1. Thomas E. Martin III

I am responding: On behalf of myself

Name: Thomas E. Martin III

Name of Organization: Elite Supply & Services, LLC - reessdata.com

Type of Organization: Professional Organization/Association

Role: Investigator/Researcher

Date Submitted: 8/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): reessdata.com

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope should explicitly recognize that biosafety depends not only on the biological agent or research activity, but also on the engineering controls and facility conditions that determine whether a biohazard is contained.
An important potential gap is oversight of real-world building and containment performance. Ventilation, directional airflow, room-pressure relationships, exhaust pathways, filtration, alarms, and related controls can affect exposure risk when biohazards are present.
I recommend that NIH ensure the policy covers failures or degradation of required engineering controls as part of biosafety oversight and requires objective verification that those controls perform as intended. Written assurances alone should not substitute for measured performance.
From my perspective as a patient with lifelong asthma and an indoor environmental quality background, this is especially important for workers, patients, research participants, and visitors with respiratory or other functional vulnerabilities.
You cannot effectively manage a biohazard if you do not also verify the systems intended to contain it.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered oversight is appropriate when it is calibrated to actual risk, but federal minimum requirements should apply wherever failure of containment could create significant risks to workers, research participants, patients, visitors, or the surrounding community.
Local institutions can manage routine implementation, but higher-risk activities should receive stronger independent oversight. Risk classification should consider not only the biohazard itself, but also the facility's engineering controls, fresh air ventilation / RH at 50% and containment requirements, potential consequences of equipment or building-system failure, and the vulnerability of potentially exposed populations.
Each tier should have clearly defined requirements for baseline “monitoring” verification, periodic

testing, incident and near-miss reporting, corrective actions, and escalation when controls fail.
A tiered system should not create different levels of protection simply because facilities are located in different jurisdictions. Federal oversight should establish and monitor the baseline in real time; local oversight should implement and strengthen it based on facility-specific risk.

3. Continued utility of Risk Groups: Risk Groups remain useful as a starting point, but they should not be the sole basis for determining appropriate oversight, particularly when an agent is genetically modified. Genetic modification can change characteristics relevant to risk, so assessment should consider the resulting organism and research activity rather than relying only on the Risk Group assigned to the original agent.
The BSL framework in the BMBL is also important because biosafety depends on how the work is actually conducted and contained. Oversight should therefore connect the biological risk assessment with the required practices, safety equipment, facility design, fresh air ventilation, relative humidity 50% directional airflow, pressure relationships, filtration, in/out/exchange exhaust, alarms, monitoring alerts, and other engineering controls.
I recommend a risk assessment → appropriate BSL/containment → objective verification approach.
When research changes the characteristics of an agent, the risk assessment and required containment should be reevaluated in real time, and critical engineering controls should be tested to verify that they perform as intended over time.
Classification identifies risk; monitoring performance helps verify and reduce risk = containment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should make voluntary compliance practical and valuable for institutions that are not formally subject to the policy.
A voluntary framework could provide standardized checklists, model Biosafety Assurances, risk-assessment tools, engineering-control verification guidance, incident and near-miss reporting templates, and training resources that institutions can adopt without excessive administrative burden.
NIH could also establish a voluntary recognition or reporting program for organizations that demonstrate compliance with these practices. Participation should emphasize measurable outcomes, including verification of required ventilation and containment controls, documentation of deficiencies, and completion of corrective actions.
Sharing de-identified lessons from incidents, near misses, engineering-control failures, and successful corrective actions could help institutions learn from one another.
The goal should be to make strong biosafety practices accessible beyond NIH-funded research: establish the baseline, verify the controls, document outcomes, and continuously improve.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The Incident Reporting and Meeting Minutes Templates should also account for patients with asthma, respiratory limitations, or environmental sensitivities when research activities occur in hospitals or healthcare facilities.
Negative-pressure rooms and zones serve important infection-control purposes, but may not be appropriate for every patient or circumstance. When a patient with asthma reports difficulty breathing or worsening symptoms, staff should promptly assess the patient, consider relocation to an appropriate environment when feasible, and provide supplemental oxygen by an appropriate delivery method when clinically indicated under applicable medical protocols.
Incident documentation should include room pressure, ventilation status, airflow, filtration and exhaust

performance, alarms, environmental measurements, symptoms, medical response, accommodations, corrective actions, and verification of engineering controls.
From my lived experience with lifelong asthma, the indoor parameters under which I function best are approximately:
Relative humidity (RH): 50%
Air temperature (AT): 68–72°F
CO_2: 400–600 ppm
VOCs: below 250 ppb
PM2.5 and PM1: as close to zero as reasonably achievable
I have found continuous indoor environmental monitoring and air-management equipment—including devices from Airthings, uHoo, and Dyson—valuable for comparing changes in my indoor environment with changes in my respiratory symptoms and functional ability. I provide these values as my individual observed parameters and accommodation information, not as proposed universal clinical thresholds or an endorsement of a particular manufacturer.
Incident reporting should preserve patient-specific environmental information so clinicians, biosafety personnel, facility professionals, and patients can compare measured conditions, symptoms, interventions, accommodations, and outcomes over time.
Measure the environment. Assess the patient. Verify the engineering controls. Accommodate individual respiratory needs.

6. Other feedback relevant to this resource: Additional implementation guidance would be beneficial on objective measurement, verification of engineering controls, and accommodations for workers, patients, research participants, and visitors with asthma, respiratory limitations, disabilities, or other environmental vulnerabilities.
NIH should provide practical guidance for establishing baseline facility conditions and periodically verifying ventilation, airflow, room-pressure relationships, filtration, exhaust, alarms, temperature, relative humidity, CO_2, VOCs, and particulate matter where these measurements are relevant to the facility and risk assessment.
Guidance should also explain what happens when measured conditions fall outside required parameters or when an individual reports respiratory symptoms or loss of function. There should be clear procedures for documenting the condition, assessing the individual, investigating potential environmental contributors, implementing corrective actions, considering reasonable accommodations or relocation, and verifying that controls are functioning properly before closing the matter.
For healthcare settings, additional guidance should address coordination among biosafety, infection prevention, facilities/engineering, occupational health, disability/accessibility personnel, and the patient's healthcare team. Negative-pressure environments may be necessary for infection control, but patient-specific respiratory needs should also be considered when determining an appropriate care environment.
Implementation resources should include standardized checklists, measurement and commissioning guidance, incident-reporting examples, accommodation procedures, corrective-action tracking, and training on interpreting environmental measurements without assuming that a single reading proves medical causation.
From my lived experience with lifelong asthma, measuring the environment alongside symptoms and functional changes can reveal patterns that would otherwise remain undocumented.
Establish the baseline. Monitor conditions. Listen to the patient. Correct deficiencies. Verify the results.

Description: Patient-supplied conceptual illustration of fresh-air intake, stale-air exhaust, filtration and ventilation controls supporting healthier indoor environments for people with asthma and respiratory vulnerabilities.

REAL ESTATE CONNECTS:
HEALTH • ENERGY • AIR QUALITY • AFFORDABILITY • RESILIENCE
HEALTH
ENERGY
AIR QUALITY
AFFORDABILITY
RESILIENCE

LONG-TERM CARE IS REAL ESTATE WITH A HEALTH MISSION

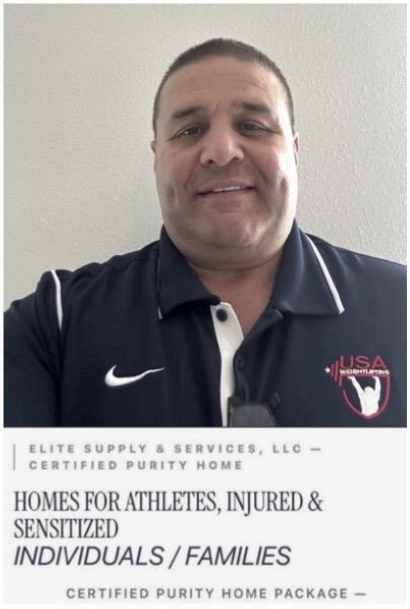
Where accessibility, comfort, care, and verified building performance meet longevity.

Healthy housing should not be a luxury upgrade. It is longevity infrastructure.

REAL ESTATE CONNECTS

Health | Energy | Air Quality | Affordability | Resilience

Housing performance affects comfort, access, operating cost, and the ability to remain safely and independently at home. Families managing asthma, chemical sensitivity, chronic health conditions, fatigue, injury, or reduced mobility may also carry costs that ordinary housing comparisons do not show.



THE HIDDEN COST OF HOUSING

- HEPA and gas-phase filtration, filter replacement, and maintenance.
- Fresh-air ventilation, dehumidification, and energy needed to operate them.
- Indoor air monitoring, safer products, water treatment, and moisture control.
- Medical care, transportation, food, relocation risk, and lost usable space or time.

WHY MEASUREMENT MATTERS

A building can look acceptable while occupied-space conditions change by room, time, weather, equipment operation, and occupant activity. Continuous trend data helps residents ask better questions and document whether corrective actions produce measurable results.

> "My mission combines real-estate and indoor-environment experience with a health, vocational, and IWF/USA Weightlifting strength-and-conditioning perspective. I understand baseline performance, recovery, access needs, and the importance of measuring change over time."

REESSDATA.COM | PUBLIC OFFICIAL & CANDIDATE BRIEF | AUGUST 17, 2026

REESSDATA.COM | BEYOND CURB APPEAL

INDOOR ENVIRONMENTAL HEALTH ALERT

Patient-documented conditions and function | Professional insight informed by lived experience

Conceptual system illustration supplied by the requester.

PURPOSE

To alert my primary-care provider and federal representatives that changes in indoor conditions have corresponded with measurable changes in my asthma symptoms and morning function. This single-patient observation requests documentation, research and verified building performance - not a claim of proven causation.

DOCUMENTED OVERNIGHT COMPARISON

08/15/2026 - controls not continuously effective

CO_2: **1,088 ppm** (peak about 1,246) | VOC: **789 ppb**
Morning: **L2-L3 symptoms and reduced function**, including wheeze and brain fog.

08/17/2026 - continuous overnight controls

Ventilation + filtration + dehumidification
CO_2: **574 ppm** | VOC: **132 ppb** | PM2.5: **2 ug/m3**
Morning: **No symptoms; asthma and productivity rated good.**

Interpretation: A temporal association in one patient - not proof of causation. CO_2 is a ventilation indicator, not a complete measure of indoor air quality.

EXAMPLES TO EVALUATE - VERIFY THE EXACT PRODUCT/SKU

TimberHP | ROCKWOOL | Knauf Insulation | Manson Insulation | CleanFiber
Also evaluate zero-/low-VOC paints, adhesives, cabinetry and sealants.

No blanket approvals or endorsements. Review product-specific emissions, ingredients, certifications and installation requirements.

PATIENT-INFORMED SYSTEM INSIGHT

As a patient with asthma since age 5 and an IEQ professional:
recirculation is not ventilation.
- Fans that only move room air do not add outdoor air.
- Outdoor air must reach occupied rooms; source areas need exhaust and transfer/return paths.
- Any patient-specific target, including 6 ACH, should distinguish outdoor-air ACH from filtration-based equivalent ACH and be professionally measured and verified.

CLINICAL + PCP ACTION

Medication remains important. If a trigger continues, medication alone may not fully control symptoms for some patients.

PCP: Document readings with symptoms and function; incorporate exposure reduction into the asthma plan; help clinicians understand accommodation needs.

CONGRESSIONAL ACTION

Support IEQ monitoring pilots; verified ventilation and moisture performance in federally supported housing and healthcare; and research involving medically vulnerable occupants.

Goal: Pair third-party macro verification with ongoing, occupant-visible monitoring and maintenance.

LIVED EXPERIENCE CAN REVEAL GAPS OTHERS MISS. Asthma and autism do not share one proven cause; study overlapping response patterns without assuming causation.

THOMAS E. MARTIN III Patient with asthma since age 5 | FL Mold Assessor MRSA #4055 | Founder, Elite Supply & Services, LLC

2. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Government Agency

Role: Institutional Review Oversight Committee Member

Date Submitted: 8/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): medical countermeasures

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: NIH should clarify how biological toxin research is categorized when the toxin is used as a research material but is not genetically modified, propagated, or otherwise altered.
The final policy should clarify the review requirements for Select Agent-listed toxins maintained below Federal Select Agent Program exclusion quantities, including whether these activities require full IBC review solely because the toxin is listed or may qualify for delegated review based on risk.
NIH should clarify how detoxified, inactivated, modified, fragmented, or otherwise non-toxic toxin derivatives are treated under the policy.
NIH should further define the boundaries of "biomedical research" when applying the policy to non-NIH-funded research at institutions receiving NIH funding, particularly federal institutions operating under multiple missions and funding authorities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The tiered review framework is appropriate, but NIH should clarify whether an institutional risk assessment may support movement between review categories when the actual risk differs from the categorical assignment.
NIH should clarify whether Select Agent-listed toxins maintained below applicable exclusion quantities may qualify for delegated IBC review based on risk assessment.
NIH should define what constitutes equivalent oversight by another federal agency and identify which NIH requirements remain applicable when research is already subject to another federal biosafety oversight program.

3. Continued utility of Risk Groups: NIH should retain Risk Groups as a baseline hazard-assessment tool, while emphasizing that RG classification does not automatically determine the appropriate Biosafety Level.
Containment decisions should continue to be based on a comprehensive risk assessment considering the agent, genetic modifications, experimental procedures, quantities, routes of exposure, and available controls.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary adoption through readily available model procedures, risk-assessment tools, training materials, templates, and decision trees rather than creating unnecessary administrative requirements.
NIH should clarify whether voluntary adoption of the policy by an otherwise non-covered institution creates additional reporting, recordkeeping, public disclosure, or other compliance obligations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: NIH should provide specific guidance for public posting and redaction of IBC minutes and incident reports involving CUI, security-sensitive information, Select Agent security information, operational security, proprietary information, or other federally protected information.
Federal institutions should be permitted to use an alternative transparency mechanism when public posting conflicts with applicable security or information-protection requirements.
NIH should coordinate incident-reporting requirements with other federal oversight programs to minimize duplicative reporting of the same event.

6. Other feedback relevant to this resource: NIH should provide a comprehensive decision tree or flowchart for determining policy applicability and whether research requires NIH + IBC, full IBC, or delegated IBC review.
Implementation guidance should include examples involving Select Agent toxins above and below exclusion quantities, non-Select Agent toxins, detoxified/inactivated toxins, and medical countermeasure research.
NIH should provide additional examples involving viral vectors, plasmids, genetically modified organisms, cell lines, animal studies, and clinical research.
NIH should establish clear qualifications and documentation requirements for delegated IBC reviewers, including whether the Biosafety Officer may serve in this role.
NIH should provide standardized risk-assessment and Biosafety Assurance templates that institutions may adapt.
NIH should clarify transition requirements for currently approved research and research newly brought into scope under the expanded policy.
Additional implementation guidance should address institutions operating under multiple federal oversight frameworks and explain how equivalent federal oversight will be recognized.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The need for a BSO seems to have changed in this new policy. Previously a BSO was needed on a committee for large scale work, however now they are only needed for BSL3 and BSL 4 work or GDMOs. I don't agree with this logic since BSL2 materials can lead to LAIs . For this reason, I believe A BSL2 designation should be included under the responsibilities of a BSO as well.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): n/a

3. Continued utility of Risk Groups: n/a

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): n/a

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: n/a

6. Other feedback relevant to this resource: Question: Since this will replace the "NIH Guidelines...", will the older classifications ((III-(a-e), III-F, etc) change as well? This new policy has summarized and combined a lot into the new section IV.

5. Paul M. Arnaboldi

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Broadly, infectious disease, neuroscience, cancer, and metabolic disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I find gaps in the policy that should be addressed in sections IV-1, 2, and 3:

In section IV-2: Research involving genetically modified cells, viruses, or organisms other than plants...directly conflicts with section IV-3 research with genetically modified RG1 biological agents. Typically a higher containment section would override a lower one. Because the research in IV-2 would also cover research with RG1 and exception should be put under IV-3

Where does research with plasmids or replication incompetent vectors that integrate fall. Please define this explicitly.

In section IV-2 there is a defined section for clinical research involving humans. Please indicate where the same research involving animals would go.

In all areas you have the words other than plants. Where does research with plants fall?

Section IV-3: Research with well-characterized cell lines. Does this now mean that any work with any cell line will now require an IBC protocol?

Section IV-3: Research conducted with transgenic organisms at BSL-1/ABSL1. Does this now mean any work with any transgenic mice, including established mice ordered from vendors will now require IBC oversight? Also please define what is meant by transgenic mice. Do you consider all genetically modified mice as transgenic. If this is not meant to refer to modified animals, other than gene drive animals, please tell us that explicitly.

Are there no longer exemption categories as under the current NIH Guidelines?

Section IV-2: Research with primary cells that may be contaminated by adventitious agents. Please clearly define what is meant by an adventitious agent.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I agree with this.

3. Continued utility of Risk Groups: I believe this is appropriate.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I agree with this

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I think the policy is overwhelming. I believe reporting every single incident to the NIH is excessive. I understand the reporting of exposures that result in interventions, but as written, this would result in reporting of every minor occurrence and would overburden the reporter and the NIH office. You might want to dial this back a bit, and reserve if for significant events. Right now it appears that it would include reporting of incidents at BSL1 which would not cause be a risk.

6. Other feedback relevant to this resource: N/A

6. N/A

6. Other feedback relevant to this resource: N/A

7. Laura Fochtmann

I am responding: On behalf of myself

Name: Laura Fochtmann

Name of Organization:

Type of Organization: Not Applicable

Role: Healthcare Provider

Date Submitted: 8/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: For any incidents in which there is a loss of containment of potentially infectious or hazardous agents, I would advocate that reporting also be required if there would be a significant risk to the health of animals or other wildlife in the community. For example, if an infectious agent poses a low risk to humans but release would pose a risk to birds, livestock, or pets in the community, I believe that it should be reportable. Depending on the affected animal/wildlife, there could be significant economic effects and there could also be risks of transformation and risk to human health at a later time.

6. Other feedback relevant to this resource: Although the CDC BMBL has now issued a clarification on service animals in laboratory settings, it would also be helpful to have that information explicitly stated in this document as well (https://www.cdc.gov/labs/pdf/Clarification-on-Service-Animals-Laboratories-Compliance-with-Federal-Laws-and-BMBL-Guidance.pdf)

Description: Feedback on proposed biosafety regulations

8. Sarah White

I am responding: On behalf of myself

Name: Sarah White

Name of Organization: Thermo Fisher Scientific

Type of Organization: Commercial Entity (Biotech/Device/Pharmaceutical Company/Small Business)

Role: Other

Role - Other: Biosafety Officer

Date Submitted: 8/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Research with genetically modified organisms, viral vectors, recombinant biology, monoclonal anitbodies, research & development and biologics manufacturing

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The new policy adequately addresses gaps identified in the prior NIH Guidelines, provides more context for genetically modified organisms, wild type biological agents and allows institutional safety professionals and IBCs to focus on health-hazard-relevant research, not simply recombinant and synthetic nucleic acids.

The acronym GDMO is used 9 times in the draft but nowhere defined, gene-drive modified organism I'm assuming?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Guidance for when NIH and/or IBC approvals prior to initiation and the addition of delegated reviews will alleviate the existing intense workload of the IBC from more routine research projects, allowing focus and discussion around topics more impactful to the institution and the surrounding community.

3. Continued utility of Risk Groups: The alignment between the NIH policy and BMBL strengthen biosafety oversight and uniformly supports risk-based assessment and management of biohazards.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): As a biosafety officer who has implemented voluntary compliance at sites who manufacture viral vectors, and contract and development manufacturing facilities, the updates will streamline IBC reviews and alleviate project management pressures as IBC approval is currently a gating activity for majority of incoming work. With these changes AAV vector work will no longer be gated by IBC approval with the addition of delegated reviews.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Templates are clean and contain all pertinent information respectively.
One suggestion for the Draft Meeting Minutes Template is to reorder the rows under New IBC Registrations and Amendments for Review such that the Readout of Any Projects Approved by Delegated

Review isn't inserted between the Project Overview and Risk Assessment and Discussion; suggest to either move it to the first row in this section or after IBC Vote.

Add a separator row above New Business/Additional Topics so that these appear separate from IBCE Registrations and Amendments for Review

6. Other feedback relevant to this resource: N/A

9. Daron L. Davis

I am responding: On behalf of myself

Name: Daron L. Davis

Name of Organization: Independent Scholar

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 8/21/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Institutional governance, public accountability, multilevel governance, and governance of biomedical research oversight

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's effort to broaden biosafety oversight beyond a narrow set of research categories. My principal concern is not the scientific definition of "biohazard," on which I defer to subject-matter experts, but the institutional perimeter created by the proposed scope.

The draft appears to extend requirements beyond NIH-funded projects to non-NIH-funded biomedical research conducted at or sponsored by institutions receiving NIH funding. NIH should therefore clarify how institutional responsibility attaches when the sponsoring institution, physical research site, IBC of record, shared core facility, affiliated entity, or off-site research location are not identical.

For covered research, the policy or implementation guidance should identify the institution whose Biosafety Assurance governs the activity, the IBC of record, the institution responsible for local implementation of IBC directives, incident reporting, corrective action, public posting, and return to approved standing.

This would reduce inadvertent oversight gaps without requiring unnecessary centralization. Distribution of research activities across institutions is not inherently problematic; ambiguity about which institution retains which authority-bearing function is.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered oversight is appropriate in principle because different levels of risk do not require identical decision structures. The governance issue is whether delegation and distributed oversight remain sufficiently attributable and bounded.

NIH should provide an implementation-level authority matrix for major biosafety decisions identifying:

decision or action → authority holder → permitted delegate → scope → conditions → duration → escalation authority → corrective/override authority → required record.

This is particularly important for delegated IBC review, externally administered IBCs, and research also subject to another federal agency's oversight.

Where another federal agency has overlapping jurisdiction, NIH should specify whether that oversight supplements NIH oversight, substitutes for a defined NIH function, or governs only a particular regulatory determination. The policy should also identify which NIH responsibilities remain, including incident reporting, Biosafety Assurance oversight, corrective authority, and funding-related enforcement where applicable.

Tiering should therefore calibrate not only scientific review intensity to risk, but also the visibility of who possesses authority, who exercises it, and who can intervene when conditions change.

3. Continued utility of Risk Groups: I do not offer a substantive recommendation on the comparative scientific utility of Risk Groups versus Biosafety Levels as a baseline for biological risk assessment. That determination should be informed primarily by biosafety, microbiology, infectious-disease, and related scientific expertise.

From a governance perspective, however, whatever classification architecture NIH adopts should make clear:

1. who is authorized to make the initial classification;
2. what evidence and criteria support that classification;
3. when modification of an agent requires reassessment;
4. who may require a more protective classification or containment level;
5. how disagreements are escalated; and
6. how classification changes are recorded over the life of the protocol.

This would preserve traceability without substituting governance analysis for scientific risk judgment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary compliance through usable governance infrastructure rather than attempting to reproduce mandatory enforcement mechanisms for institutions outside the policy's formal jurisdiction.

Useful mechanisms could include standardized model Biosafety Assurance materials, voluntary IBC templates, incident-reporting tools, decision and delegation records, training resources, and technical assistance that non-NIH-funded institutions can adopt without representing themselves as formally NIH-approved where that is not the case.

NIH should also distinguish clearly between voluntary adoption of NIH practices and formal NIH oversight. Voluntary use of a template, reporting system, or biosafety standard should not create ambiguity about whether NIH possesses authority over an institution or has approved its program.

A voluntary pathway will be more credible if institutions can obtain the benefits of standardized

governance, documentation, and learning without uncertainty about the legal or institutional status created by participation.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed templates should preserve the lineage of consequential decisions while avoiding duplication of information already captured through existing NIH IBC documentation.

For IBC meeting minutes, NIH should consider adding fields for:

oversight category;
full-IBC versus delegated review;
authority for delegated review;
cross-agency authorization where applicable;
NIH determination/reference where applicable;
current protocol approval period and standing;
material modification history;
conflict-of-interest recusals and the number of unconflicted members eligible to decide the matter; and
corrective or return-to-standing actions.

For incident reports, NIH should consider fields for:

event date/time;
date/time of designated institutional awareness;
initial reporting actor and receiving office;
preliminary classification and classification authority;
subsequent changes in classification and their basis;
NIH-reportability determination;
corrective decision and responsible authority;
public-record version/date;
NIH final response where applicable; and
closure authority and current research standing.

NIH should also clarify when the proposed 24-hour reporting clock begins and whether every listed approval or compliance violation automatically triggers immediate reporting or only those meeting the policy's stated significant-risk threshold.

For public incident reporting, I recommend a two-layer record architecture: an authoritative institutional record preserving complete decision and correction lineage, and a public-facing version subject to standardized lawful redaction. Material corrections should result in visible version history rather than silent replacement.

6. Other feedback relevant to this resource: Additional implementation guidance would be particularly useful in six areas.

First, institutional scope. NIH should identify the institution of record and local implementation authority

for multi-site, affiliated, off-site, shared-core, sponsored, and externally reviewed research.

Second, externally administered IBCs. Guidance should identify who retains local implementation, inspection, incident-response, recordkeeping, emergency-action, and corrective authority when the IBC itself is external.

Third, corrective authority. NIH should publish a clear map showing who may immediately pause research, impose temporary conditions, modify or revoke delegated approval, suspend IBC approval, escalate disagreement, and authorize return to approved standing.

Fourth, conflict of interest and quorum. Where a conflicted member may count toward meeting quorum but may not participate in a specific decision, NIH should require visibility into the number of unconflicted members actually eligible to decide that protocol and consider a decision-specific unconflicted quorum.

Fifth, the National Biosafety Data and Safety Analysis Center. NIH should clarify repository access, correction, retention, versioning, institutional updates, derivative analyses, and whether NBDSAC outputs constitute technical analyses, recommendations, or merely inputs into a separate NIH decision process.

Sixth, transition. Because the policy is proposed to become effective six months after publication and will affect ongoing research, NIH should provide a transition plan addressing existing protocols, current approvals, Biosafety Assurances, external IBC arrangements, incident records, and the sequencing of any required reclassification or re-review.

These recommendations are developed through my Institutional Authority Dynamics research program, particularly Institutional Authority and Governance Dynamics (IAGD 2.3), Authority-Control Alignment, the Institutional Layer Separation Principle, Institutional Boundary Enforcement, and Authority Provenance. The application is analytical and does not constitute empirical validation of the frameworks or imply NIH adoption.

Uploaded File: Daron_L_Davis_NIH_NOT-OD-26-112_Biosafety_PUBLIC_COMMENT.pdf

Description: Full public comment: governance analysis of the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112), applying Institutional Authority Dynamics, IAGD 2.3, Authority-Control Alignment, ILSP, IBE, and Authority Provenance.

PUBLIC COMMENT ON DRAFT NIH BIOSAFETY POLICY FOR RESEARCH INVOLVING BIOHAZARDS

Notice No. NOT-OD-26-112

National Institutes of Health - Office of Science Policy

Submitted by Daron L. Davis

Independent Black Governance Researcher and Public Scholar

August 21, 2026

To the National Institutes of Health Office of Science Policy

I submit this comment on the Draft NIH Biosafety Policy for Research Involving Biohazards issued under Notice No. NOT-OD-26-112. I support NIH's objective of modernizing biosafety oversight so that it remains transparent, adaptive, accountable, and calibrated to risk. The draft policy substantially strengthens institutional governance by expanding coverage to a broader range of biohazards, establishing tiered oversight, requiring NIH-approved Biosafety Assurances, strengthening Institutional Biosafety Committees (IBCs), formalizing incident reporting, and expanding public transparency.

My recommendations focus on a narrower governance question: as biosafety oversight becomes more distributed across NIH, institutions, IBCs, delegated reviewers, Biological Safety Officers (BSOs), Principal Investigators (PIs), externally administered IBCs, and other federal agencies, how can the policy preserve clear authority, authorization, accountability, provenance, institutional boundaries, and corrective control?

Research basis and analytical approach

I submit this comment as an independent Black governance researcher and public scholar developing the Institutional Authority Dynamics research program, an integrated political-science research enterprise examining how institutional authority is formed, exercised, distributed, governed, preserved, defended, and made accountable across complex governance systems.

This submission applies a bounded set of components from that research architecture:

- Institutional Authority and Governance Dynamics (IAGD 2.3) - the integrating theoretical architecture. IAGD treats Authority-Control Alignment as the central hinge between formally constituted Institutional Authority and practical Governance Control.
- Authority-Control Alignment - assessed across four dimensions: Locational (authority and control reside where intended); Authorization (actor, action, scope, conditions, and period are authorized); Accountability (actors answer for Authority Exercise); and Corrective (institutions detect, intervene, and correct).
- Institutional Layer Separation Principle (ILSP) - differentiates Governance, Authority, Execution, and Infrastructure so authority-bearing functions remain distinguishable and data movement remains traceable.
- Institutional Boundary Enforcement (IBE) - maintains jurisdictional, procedural, functional, and accountability boundaries and guards against persistent boundary failure.
- Authority Provenance - the cross-cutting evidentiary layer tracing consequential claims, decision rights, delegations, Authority Exercise, and Governance Control arrangements to their source, recognition, authorization, transformations, retained rights, and present standing.

This is a bounded public-policy application of the research program. It does not constitute empirical validation of these frameworks, determine whether a particular biosafety decision is scientifically or legally correct, or imply adoption of the research by NIH.

Executive summary of recommendations

1. Define the institutional perimeter of responsibility for research that is conducted at or sponsored by an NIH-funded institution, especially for affiliated entities, shared cores, off-site work, multi-site research, and externally administered IBCs.
2. Clarify when oversight by another federal agency supplements, substitutes for, or controls only a defined function of NIH oversight, and identify which NIH responsibilities remain.
3. Carry forward and make explicit the authority and accountability controls for delegated review and externally administered IBCs, including local implementation and override responsibility.
4. Strengthen decision integrity where conflicted IBC members may count toward quorum by requiring a decision-specific record of unconflicted voting capacity.
5. Clarify incident-reporting triggers, the point at which the 24-hour clock begins, the distinction between preliminary and final classifications, and the governance of public incident records.
6. Use the incident-reporting and IBC-minute templates to preserve policy-specific provenance rather than duplicating information already captured in NIH's existing meeting-minute guidance.
7. Make corrective authority and return-to-approved-standing as explicit as initial approval authority.
8. Define governance, access, correction, versioning, and analytical-status controls for the National Biosafety Data and Safety Analysis Center (NBDSAC).
9. Provide a transition architecture for existing protocols, Biosafety Assurances, externally administered IBC arrangements, and current approvals during the six-month implementation period.

I. Define the institutional perimeter and cross-agency authority configuration

A. Clarify the institutional perimeter of responsibility

The draft policy applies not only to NIH-supported research, but also to non-NIH-funded biomedical research conducted at an institution that receives any NIH funding. It further provides that, as a term and condition of NIH funding, institutions shall ensure that research conducted at or sponsored by the institution, irrespective of funding source, complies with the policy.

This expansion creates an important institutional-boundary question. The final policy or implementation guidance should define how responsibility attaches when research is conducted through affiliated entities, shared core facilities, off-site laboratories, multi-site studies, clinical locations, or other arrangements in which the sponsoring institution, physical research site, and local oversight body are not identical.

I recommend that NIH require an identifiable responsibility record for covered research that states, as applicable:

- the institution whose Biosafety Assurance governs the activity;
- the physical site where research is conducted;
- the IBC of record;
- the institution responsible for local implementation of IBC directives;
- the responsible BSO or other designated official;
- the institution responsible for incident reporting and public posting;
- the institution with immediate corrective authority; and
- the institution responsible for confirming return to approved standing.

This is principally an IBE and Locational Alignment issue. Distribution across institutions is not inherently problematic; ambiguity about which institution retains which authority-bearing function is.

B. Clarify overlapping federal oversight

The draft states that covered research also under the regulation or purview of another federal agency may proceed under the oversight of that agency once applicable approvals or clearances have been obtained. This provision should be clarified because 'under the oversight of the other federal agency' may describe several materially different relationships.

The final policy should specify whether another federal agency's oversight:

- supplements NIH oversight;
- substitutes for a defined NIH review function;
- controls only a specific regulatory determination;
- changes institutional incident-reporting obligations;
- changes containment or corrective authority; or
- leaves NIH funding, Assurance, and enforcement authority intact while another agency governs the underlying research activity.

Whenever overlapping federal jurisdiction applies, the record should identify the operative authority configuration: NIH authority, other federal authority, institutional authority, the affected decision right, continuing NIH responsibilities, reporting pathways, and corrective authority.

II. Govern delegated review and externally administered IBCs as distinct authority arrangements

A. Delegated review

The draft permits lower-risk research and minor amendments to be reviewed and approved by an individual or subgroup of IBC members. Delegated reviewers may elevate matters to the full IBC, and all delegated approvals must be reported in full to the IBC at its next scheduled meeting.

This is a reasonable streamlining mechanism, but the record should preserve the difference between authority exercised by the full IBC and authority exercised under delegation.

For delegated review, NIH should require or recommend documentation of:

- the provision authorizing delegated review;
- the reviewer or subgroup exercising delegated authority;
- the research category or amendment qualifying for delegation;
- the decision and conditions of approval;
- the period of authorization;
- mandatory escalation criteria;
- whether escalation was considered or required;
- the date the full IBC was notified; and
- the later full-IBC action, if any, affecting the delegated determination.

B. Externally administered IBCs

The proposed Biosafety Assurance asks institutions to disclose whether they use an externally administered IBC. Existing NIH guidance already establishes useful controls for such arrangements: the research-performing institution registers the IBC, the external IBC must possess appropriate local expertise and knowledge, and an individual at the research-performing institution must have authority and responsibility to implement the IBC's directives.

The final policy should expressly preserve or incorporate those safeguards so the modernization effort does not inadvertently make external review less governable than current practice.

For externally administered IBCs, the final implementation materials should identify:

- which institution is the IBC of record;
- who possesses local implementation authority;
- how local facility, training, and operating information reaches the external IBC;
- who performs local inspections and periodic compliance review;
- who receives and investigates incidents;
- who may impose an immediate local pause or additional biosafety condition;
- who maintains authoritative records and public postings; and
- how disagreements between the external IBC and the research-performing institution are resolved.

ILSP is especially useful here: review, local execution, institutional responsibility, and technical infrastructure may be distributed while remaining distinguishable.

III. Strengthen decision integrity where conflict-of-interest recusals interact with quorum

The draft appropriately prohibits an IBC member from reviewing or approving a project in which the member is engaged or expects to be engaged, or in which the member has a direct financial or other conflict of interest. The draft also provides that a recused member may nevertheless be counted toward the voting quorum for the meeting.

That design can create a decision-specific governance problem: a meeting may satisfy the formal meeting quorum while the number of unconflicted members eligible to decide a particular protocol is smaller.

I recommend that NIH require the meeting record to identify, for each affected decision, the recused member, the basis for nonparticipation at an appropriate level of detail, the number of voting members eligible to participate in that decision, and whether the decision-specific eligible membership satisfied the required voting threshold.

NIH could go further and require an unconflicted decision-specific quorum. At minimum, the record should make visible whether formal meeting quorum and actual decision capacity diverged.

This recommendation builds on NIH's existing 2025 IBC meeting-minute guidance, which already calls for documentation of quorum, member attendance, voting results, conflicts, protocol identifiers, risk assessments, conditions of approval, and verification of conditions. The new policy-specific template should extend that record rather than duplicate it.

IV. Clarify incident classification, reporting triggers, public records, and templates

A. Clarify the 24-hour reporting trigger and institutional awareness

The draft requires immediate NIH notification, within 24 hours or as soon as the institution becomes aware, for incidents posing a significant risk to human health. The listed reportable events include confirmed or potential laboratory-acquired infections, certain releases, high-containment incidents, specified BSL-2 exposures, and any compliance violations at any BSL/ABSL such as failure to obtain or maintain required IBC or NIH approval.

The final policy should clarify two points. First, NIH should state whether every listed compliance violation is automatically subject to the immediate reporting requirement or whether the violation must also satisfy the stated significant-risk threshold. Second, NIH should define when the 24-hour clock begins.

For example, 'institution becomes aware' could mean awareness by the PI, BSO, IBC Chair, AOR, institutional biosafety office, or another designated official. A defined institutional-receipt trigger would support consistent reporting and avoid incentives to argue over which individual's knowledge starts the clock.

B. Preserve classification lineage

The incident record should distinguish an event from the institutional and federal classifications later assigned to it. A useful lineage is:

event -> initial notification -> preliminary classification -> investigation -> verified facts -> institutional determination -> NIH-reportability determination -> corrective action -> final report -> NIH response -> closure

The template should separately identify incident, near miss, anomaly, suspected exposure, confirmed exposure, policy violation, preliminary information, verified fact, institutional determination, NIH determination, and final disposition where those distinctions apply.

C. Use a two-layer public-record architecture

The draft requires all incident reports to be posted on an institutional public-facing webpage, with final reports posted within 30 days of NIH's final response for NIH-reportable incidents or within 30 days of institutional

finalization for incidents not reportable to NIH. NIH's final response must be posted with NIH-reportable incidents. IBC meeting minutes and incident reports must remain publicly posted for at least five years.

I support the transparency objective. The final implementation design should distinguish the authoritative institutional record from the public-facing record.

I recommend a two-layer approach:

- Authoritative record - preserves complete provenance, internal correction history, decision lineage, and any information lawfully maintained by the institution.
- Public-facing record - contains the required incident or meeting information after standardized redaction for privacy, proprietary interests, national security, or other permissible protections.

When the authoritative record is materially corrected, the public version should be updated with a visible correction or version history rather than silently replaced. This preserves transparency while avoiding the inference that every initially reported fact remained unchanged after investigation.

D. Add new-policy fields to the required templates

NIH specifically requests comment on incident-reporting and IBC meeting-minute templates. Existing NIH meeting-minute guidance already captures substantial decision provenance. The modernization templates should therefore add only what the new policy's architecture requires.

For IBC meeting minutes, NIH should consider adding fields for:

- oversight category under Section IV;
- full-IBC versus delegated review;
- delegated-review authority and reviewer identity or role;
- cross-agency authorization or clearance where applicable;
- NIH determination or reference where applicable;
- current protocol approval period and standing;
- material modification lineage;
- decision-specific conflict recusals and eligible voting capacity; and
- corrective or return-to-standing action when a prior approval has been paused or modified.

For incident reports, NIH should consider adding fields for:

- date and time of event;
- date and time of designated institutional awareness;
- initial reporting actor and receiving institutional office;
- preliminary incident classification and classification authority;
- changes in classification and the basis for change;
- NIH-reportability determination;
- corrective decision and responsible authority;
- public-record version/date;
- NIH final response, when applicable; and
- closure authority and current research standing.

V. Make corrective authority and return to approved standing as explicit as initial approval authority

The draft already assigns meaningful corrective responsibilities. The BSO investigates incidents and reports significant problems; the IBC reviews incidents and determines whether additional biosafety measures are warranted; NIH reviews reportable incidents, verifies institutional responses, and may require additional action; and NIH may restrict or withdraw Biosafety Assurances.

The remaining gap is narrower: the policy is less explicit about the immediate and intermediate authority sequence when previously approved research must be paused, modified, or restored.

Implementation guidance should identify, by research category:

- who may order an immediate pause;
- who may impose temporary containment or procedural conditions;
- who may modify or revoke a delegated approval;
- who may suspend or modify an IBC approval;
- what emergency authority a BSO or designated official possesses;
- when NIH involvement becomes mandatory;
- how disagreement among the PI, BSO, IBC, institution, and NIH is escalated;
- what record is required for emergency action; and
- who authorizes return to approved standing after correction.

The governing principle is that the institution authorized to approve research should not be easier to identify than the institution authorized to stop, modify, or restore it.

VI. Define governance and provenance controls for the NBDSAC

The draft establishes the National Biosafety Data and Safety Analysis Center as an FFRDC that independently aggregates, de-identifies, and analyzes laboratory biosafety incident data, near misses, and anomalies. Institutions are encouraged to submit voluntary confidential reports, and NIH states that voluntarily submitted data will not be used for enforcement or funding action where the incident did not result in an environmental release or laboratory-acquired infection.

This is a promising learning architecture. The final policy or implementation materials should nevertheless distinguish technical analysis from NIH Authority Exercise and define Governance Control over the repository.

NIH should clarify:

- which entity governs repository access and access authorization;
- retention periods for raw, transformed, and derivative datasets;
- how institutions correct, supplement, or update submitted records;
- whether and how institutions may withdraw voluntary submissions;
- how de-identified records preserve version lineage without exposing institutional or individual identities;
- how derivative analyses identify the data version or corpus used;
- what review applies before analytical findings are published or used in policy development; and
- whether NBDSAC outputs are technical analyses, recommendations, or inputs to a separate NIH decision process.

The last distinction is important because expertise, technical custody, or analytical control do not by themselves establish Institutional Authority. Authority Provenance should preserve the path from NBDSAC analysis to any later NIH policy or enforcement decision without treating the FFRDC's analytical role as equivalent to NIH decision authority.

VII. Provide an explicit transition architecture for existing research and institutional arrangements

NIH proposes that the final policy become effective six months after publication and apply to existing awards and agreements, ongoing intramural research, and non-NIH-funded biomedical research at institutions receiving NIH funding. Biosafety Assurances may be approved for up to four years, while protocol approvals may extend for up to three years.

A six-month transition can succeed only if institutions know which existing approvals remain valid and which must be reclassified, re-reviewed, or incorporated into a new Biosafety Assurance.

NIH should provide implementation guidance addressing:

- whether currently approved protocols remain valid through their existing approval periods;
- which ongoing activities require reclassification under the new Section IV tiers;
- whether existing IBC registrations convert into or inform the new Biosafety Assurance;
- deadlines and sequencing for initial Biosafety Assurance approval;
- how existing externally administered IBC arrangements transition;

- treatment of pending amendments and new protocols during the transition period;
- how current incident records and public-posting obligations migrate into the new system; and
- a staged implementation option if full immediate re-review would create an avoidable institutional backlog.

This directly addresses NIH's request for feedback on administrative burden and implementation resources. A transparent transition architecture can preserve accountability without forcing institutions to reconstruct every governance relationship at once.

VIII. Preserve and build upon the draft policy's existing governance strengths

The draft already contains substantial governance infrastructure that should be retained. It requires institutional lines of authority, NIH-approved Biosafety Assurances, independent IBC risk assessment, periodic review, conflict-of-interest restrictions, unaffiliated community membership, incident review and reporting, public minutes, public incident reports, defined NIH review for specified higher-risk activities, and reporting of delegated approvals to the full IBC.

Existing NIH guidance for externally administered IBCs and IBC meeting minutes also provides useful controls that should be carried forward rather than displaced. My recommendations are intended to connect these existing and proposed safeguards into a clearer authority, provenance, boundary, and corrective-control architecture.

Consolidated recommendations

1. Define the institution of record and local implementation authority when covered research crosses institutional, geographic, sponsorship, or oversight boundaries.
2. Clarify whether other federal-agency oversight supplements, substitutes for, or controls only a defined function of NIH oversight.
3. Document delegated-review authority, scope, escalation, duration, and full-IBC reporting.
4. Expressly preserve current safeguards for externally administered IBCs, including local knowledge and local implementation authority.
5. Require decision-specific visibility into conflict recusals and unconflicted voting capacity; consider a decision-specific unconflicted quorum.
6. Clarify whether all listed compliance violations trigger 24-hour reporting and define the event that constitutes institutional awareness.
7. Preserve incident classification lineage from initial report through final disposition.
8. Use an authoritative-record/public-record model with visible correction and version history.
9. Add policy-specific provenance fields to the incident-reporting and IBC-minute templates rather than duplicating existing minute requirements.
10. Publish a corrective-authority map for pause, modification, override, emergency action, escalation, and return to approved standing.
11. Define NBDSAC repository governance, correction, versioning, access, and the institutional status of its analytical outputs.
12. Publish a transition plan for existing protocols, Biosafety Assurances, external IBCs, incident records, and ongoing research during the six-month implementation period.

Conclusion

The draft NIH Biosafety Policy recognizes that modern biomedical research requires a more distributed and adaptive oversight system. Distributed governance can improve expertise, responsiveness, risk calibration, and institutional learning. It also increases the importance of knowing where authority resides, who is authorized to exercise it, how consequential decisions move across institutional layers, who remains accountable, and who possesses corrective control when conditions change.

A durable governance principle follows: oversight should not distribute Authority Exercise faster than institutions can preserve its location, authorization, accountability, provenance, boundaries, and corrective control.

The draft already contains much of the infrastructure necessary to meet that standard. Clearer institutional perimeters, cross-agency rules, delegation records, decision-integrity controls, incident provenance, corrective pathways, NBDSAC governance, and transition guidance would strengthen the architecture without requiring unnecessary centralization.

Respectfully submitted,

Daron L. Davis

Independent Black Governance Researcher and Public Scholar

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Baseline commissioning and periodic verification of required ventilation and containment controls using calibrated equipment.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Documentation of applicable fresh air airflow, pressure relationships, exhaust pathways, HEPA-filter integrity, alarm performance, maintenance, deficiencies, and corrective actions.

3. Continued utility of Risk Groups: Incident and near-miss reporting that captures ventilation failures, abnormal pressure or airflow, equipment failures, potential exposures, reported symptoms, and medical responses.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Occupational-health and disability planning for workers, patients, and research participants with asthma, reduced respiratory function, or other health vulnerabilities.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public summaries identifying when engineering controls were verified, what deficiencies were found, and whether corrective actions were completed—while protecting security and personal information.

6. Other feedback relevant to this resource: Patient symptoms alone do not establish causation, and consumer monitors do not certify laboratory performance. However, reported symptoms, sensor anomalies, equipment alarms, and repeatable patterns should trigger a qualified investigation rather than dismissal.

Establish the baseline. Verify the controls. Document incidents and outcomes. You cannot manage what you do not monitor.

6. Other feedback relevant to this resource: The guidance states that “IBC approval is required to lower the containment of wild-type or genetically modified RG3 or RG4 biological agents that NIH has previously approved to be conducted at lower containment.” It would be helpful for NIH to provide additional guidance or a publicly available list identifying the wild-type or genetically modified RG3/RG4 agents that have previously been approved for work at lower containment levels. It is currently unclear how institutions are expected to determine whether a particular agent has received such prior NIH approval. Additionally, clarification would be helpful regarding whether these approvals are specific to individual projects or institutions (e.g., NIH-funded research) or whether a prior NIH approval may be applied more broadly when an IBC evaluates similar work.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The inclusion of the non-specific term "toxins" is problematic as defined. The proposed rules define "toxins" as "A protein or peptide produced by living organisms that causes harm in humans." This definition effectively turns any work with any cell - regardless of lack of genetic alterations - into a "biohazard" as virtually any cell produces proteins that can cause harm in humans. For example, many types of cells produce classes of proteins known as cytokines. While these are normally signaling proteins, they in humans they can become elevated to the point of becoming a medical emergency - "cytokine storm" - thus demonstrating harm. As such, even someone doing simple work culturing very basic endothelial cells is engaged in "biohazardous" work due to the ability of those cells to produce a protein - any of a number of cytokines - that has the potential to cause harm. This illustrates why the definitions proposed are vague, unworkable, and require revision.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer, general research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Perspective of Respondent
I am a biomedical scientist with extensive experience conducting cancer research using established human cancer cell lines, genetically modified cells, and animal xenograft models. I also served as a member of an Institutional Biosafety Committee for approximately 20 years, including many years as Chair. These comments therefore reflect experience both as an investigator conducting laboratory research and in the institutional oversight and risk assessment of such research. These comments are submitted in my individual capacity and are not submitted on behalf of my institution.
Clarify whether well-characterized human cell lines are actually within the scope of the Policy

There appears to be an important ambiguity between Section II and Section IV-3.

Section II defines covered biohazards as disease-causing biological agents, genetically modified cells or organisms, toxins/prions, or cells or organisms containing such hazards. A well-characterized, unmodified human cancer cell line without an identified infectious agent does not clearly meet this definition.

Nevertheless, Section IV-3 specifically identifies “research with well-characterized cell lines” as research requiring delegated review and approval.
NIH should clarify whether all established human cell lines are intended to fall within the Policy, or only those that otherwise meet the definition of a covered biohazard.

Established cancer cell lines are used in a large fraction of routine biomedical research. Ambiguous language could result in institutions interpreting essentially all human cell-culture research as subject to IBC oversight, even when no infectious agent or other defined biohazard is present.

There is also a scientifically important difference between primary human material that may contain unknown adventitious agents, established cell lines with incomplete characterization, and authenticated, well-characterized cell lines with no known infectious hazard. The draft already recognizes this

distinction by placing primary cells potentially contaminated by adventitious agents into a higher category of review than well-characterized cell lines. NIH should make the implications of that distinction explicit.

Suggested NIH clarification:
Well-characterized, established human or animal cell lines that have not been genetically modified, do not contain a known or reasonably suspected infectious biological agent or other biohazard covered by this Policy, and do not otherwise meet the definition of research involving biohazards are outside the scope of the Policy.
For cell lines that are within the Policy solely because they have been genetically modified, the risk assessment should focus on the biological consequences of the modification rather than treating genetic modification itself as evidence of increased hazard.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Clarify the treatment of BSL-1 and other very-low-risk research

The draft appropriately excludes research involving wild-type RG1 biological agents from the Policy. However, genetically modified RG1 agents, transgenic organisms at BSL-1/ABSL-1, and other low-risk materials remain subject to prior review and approval, albeit through delegated review.

This creates the potential for very-low-risk research to receive controls that are not clearly proportional to the hazard identified in the protocol-specific risk assessment.

The stated goal of the revised Policy is to expand appropriate biosafety oversight while reducing unnecessary administrative burden for low-risk research. For this objective to be realized, institutions need clearer direction that BSL-1 and equivalent low-risk research should not automatically acquire BSL-2 practices or additional engineering controls simply because it technically falls within the scope of the Policy. Risk mitigation should be proportional to the identified hazard, not simply to the fact that genetic modification has occurred.

Suggested NIH clarification:

For research involving RG1 agents, BSL-1/ABSL-1 transgenic organisms, and other low-risk biological materials, additional containment practices or engineering controls beyond those appropriate to BSL-1/ABSL-1 should be required only when the protocol-specific risk assessment identifies a scientifically plausible hazard and exposure pathway that warrants those additional controls.

NIH should also encourage institutions to establish standardized or expedited delegated-review procedures for recurring categories of low-risk research rather than requiring protocol-by-protocol reconsideration of well-established activities.

More generally, additional containment requirements should be proportional to risk and supported by an identified biohazard, a scientifically plausible route of exposure, and an assessment of both the likelihood and potential consequence of that exposure.

Local IBC discretion remains important because facilities, personnel, and experimental circumstances differ. However, local discretion should operate within an evidence-based framework established by NIH so that low-risk research is not subjected to substantially different containment requirements among institutions based primarily on theoretical rather than reasonably supported hazards.

3. Continued utility of Risk Groups: RG and BSL should both remain useful components of risk assessment, but they should not be treated as interchangeable.

RG primarily characterizes the inherent hazard associated with a biological agent, whereas BSL describes a combination of containment practices, safety equipment, and facility requirements appropriate to particular work. The appropriate containment for an experiment should therefore be determined through protocol-specific risk assessment that considers both the biological properties of the material and the manipulations being performed.

Assignment of a material or experiment to BSL-2 should not automatically imply that every manipulation requires every available BSL-2 engineering control. Conversely, a particular manipulation may warrant additional controls when it creates a credible exposure pathway.

NIH should preserve this distinction explicitly in the final Policy and implementation guidance. For genetically modified agents, the starting RG of the parent agent remains useful, but the actual effects of the modification on pathogenicity, replication, host range, transmissibility, and other relevant properties should determine whether the risk has increased, decreased, or remained unchanged. Genetic modification itself should not be treated as evidence that risk has increased.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comment. My comments are focused on NIH-supported and institutionally overseen research, risk-proportionate oversight, and implementation guidance for low-risk biomedical research.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: No comment at this time.

6. Other feedback relevant to this resource: I strongly recommend that NIH implementation resources provide additional guidance in the following four areas. Based on my experience both conducting biomedical research and serving for approximately 20 years on an IBC, including many years as Chair, these are areas in which lack of clear guidance can result in substantial variation among institutions and precautions that may not be proportional to the identified risk.

1. Routine xenograft research with established human cancer cell lines

Routine implantation or injection of established human cancer cells into laboratory mice is common in cancer research. Institutional requirements for these experiments can vary, including requirements for biosafety-cabinet use based on the possibility of an unrecognized infectious agent even when no agent has been identified. Clear NIH guidance would help ensure that such requirements are tied to protocol-specific evidence and plausible exposure pathways.

There are legitimate hazards associated with these procedures, particularly the use of sharps and the possibility of accidental inoculation of viable cells. Those risks should be addressed. However, the hazard presented by accidental percutaneous inoculation is fundamentally different from an inhalational infectious hazard. A risk assessment should distinguish among accidental needle-stick or self-inoculation, splash or mucosal exposure, adventitious infectious-agent exposure, and aerosol-mediated exposure.

The fact that human tumor cells can form a tumor in an immunodeficient mouse does not, by itself, demonstrate that those cells constitute an aerosol-transmissible infectious hazard to laboratory personnel.

Suggested NIH clarification:

For animal studies involving well-characterized human cell lines, containment and procedural requirements should be based on identified or reasonably supported hazards associated with the cell line and the experimental procedure. The ability of a cell line to form a tumor in an experimental animal should not, by itself, be considered evidence of an infectious or aerosol-transmissible hazard.

When the primary identified hazard is accidental inoculation of viable cells through the use of sharps, risk mitigation should primarily address that exposure pathway. Additional containment measures intended to prevent inhalational exposure should be required only when an inhalational hazard has been identified through the protocol-specific risk assessment.

2. Clarify when use of a biosafety cabinet is actually required

Section V-E identifies biosafety cabinets as one possible form of primary containment but does not establish criteria for determining when a biosafety cabinet is necessary. Without additional guidance, BSL-2 designation could be interpreted as supporting routine BSC use even for manipulations in which the protocol-specific assessment has not identified a meaningful exposure pathway that the BSC is intended to mitigate.

A biosafety cabinet is an engineering control. Like any engineering control, its use should correspond to an identified hazard. BSL designation should not be interpreted to mean that every manipulation associated with that BSL must necessarily be performed within a BSC.

For example, a procedure involving a needle and syringe may primarily present a percutaneous inoculation hazard. Conducting the procedure inside a BSC does not eliminate the sharps hazard and may not materially reduce the primary risk. Conversely, manipulations of infectious material that generate respirable aerosols may clearly warrant primary containment.

Suggested NIH clarification:

Assignment of BSL-2 or ABSL-2 containment does not, by itself, require that every manipulation be performed within a biosafety cabinet. The requirement for use of a biosafety cabinet or other primary containment device should be based on the specific agent, procedure, quantity, route of exposure, and

likelihood and consequence of exposure identified in the protocol-specific risk assessment.

When an IBC requires an engineering control beyond standard practices for the assigned containment level, the risk assessment should identify the specific hazard and credible exposure pathway addressed by that control.

3. Define aerosol generation in terms of biological risk rather than merely physical aerosol production

Section V-D appropriately identifies generation of aerosols as a factor that can modify risk. However, the term “generation of aerosols” is sufficiently broad that almost any manipulation of liquid biological material could theoretically be described as aerosol generating.

Aerosol risk depends upon more than whether microscopic droplets can theoretically be produced. A meaningful aerosol hazard requires consideration of whether the material in the aerosol can cause harm; whether the procedure produces particles capable of reaching an appropriate route of exposure; whether the material remains viable or biologically active; the quantity or concentration potentially generated; the infectious or harmful dose, where known; and whether inhalation or mucosal deposition is a biologically plausible route of exposure.

Without this distinction, the theoretical ability to create droplets during pipetting, injection, animal inoculation, or other commonplace procedures could become sufficient justification for additional containment even where no inhalational hazard has been demonstrated.

Suggested NIH clarification:

An aerosol-generating procedure is a manipulation that can reasonably be expected to generate droplets or particles containing a biological material in a form, quantity, and particle size capable of producing a biologically meaningful exposure through inhalation or mucosal deposition.

The theoretical physical generation of droplets or aerosol particles should not, by itself, constitute an aerosol hazard requiring additional containment. The risk assessment should consider whether the biological material presents a credible hazard through the relevant route of exposure.

4. Ensure appropriate clinical expertise is available when assessing potential human-health consequences

The proposed Policy requires IBCs to assess both the likelihood of exposure to a biohazard and the potential severity of resulting harm to research personnel. However, the proposed IBC membership requirements do not specifically require clinical or occupational-health expertise when the committee is evaluating the medical consequences of a potential exposure or developing exposure-response requirements.

Biosafety professionals have essential expertise in containment, laboratory practices, and exposure prevention. However, determining whether a particular exposure is likely to result in infection, disease,

or other clinically meaningful harm may require different expertise. This distinction is particularly important when a risk assessment involves the clinical significance of inhalation, mucosal exposure, accidental inoculation, adventitious agents, susceptibility to infection, or the appropriate medical response following an exposure.

The need is not necessarily for a physician to serve on every IBC or participate in every review. Rather, the committee should obtain relevant clinical expertise when its safety determination depends materially on a medical judgment.

Suggested NIH clarification:

When an IBC risk assessment depends materially upon the predicted human-health consequences of a potential exposure, the IBC should include or obtain consultation from an individual with appropriate clinical or occupational-health expertise relevant to the potential exposure. Such expertise may be provided by an appropriately qualified physician, occupational-health clinician, infectious-disease specialist, or other qualified healthcare professional, as appropriate to the specific risk being evaluated.

Clinical consultation should be considered particularly when the severity of a hypothetical health consequence is being used to justify additional containment, engineering controls, personal protective equipment, or restrictions on otherwise low-risk research.

Overall recommendation

The proposed Policy appropriately moves toward protocol-specific, risk-based oversight and recognizes that Risk Group and Biosafety Level are related but distinct concepts. To achieve the stated objective of reducing unnecessary burden for low-risk research, NIH should provide stronger safeguards against equating theoretical possibility with meaningful biological risk.

Additional containment requirements should be proportional to risk and supported by an identified biohazard, a scientifically plausible route of exposure, and an assessment of both the likelihood and potential consequence of that exposure.

IBC discretion remains important because local facilities, personnel, procedures, and circumstances differ. However, local discretion should operate within an evidence-based risk-assessment framework. A requirement for additional containment should identify the hazard being mitigated and explain how the required intervention materially reduces that risk. Risk assessments that depend on predicted medical consequences should also incorporate appropriate clinical or occupational-health expertise.

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 8/23/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biochemistry

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's goal of expanding the biosafety framework beyond recombinant and synthetic nucleic acid research and establishing a more comprehensive, risk-based policy. However, the proposed scope is extremely broad and should be more clearly calibrated to actual biosafety risk.

In particular, the definition of genetic modification would bring a very large amount of routine molecular and cell biology under the policy, including many experiments involving established mammalian cell lines, plasmid transfection, reporter constructs, CRISPR-modified cells, and other low-risk activities. The policy appropriately recognizes some of these activities as lower risk, but they nevertheless remain formally subject to oversight.

I recommend that NIH distinguish more clearly between research that presents a meaningful biosafety hazard and routine laboratory manipulation that is technically a genetic modification but does not materially increase risk. NIH should consider a categorical exemption or registration-only pathway for well-characterized low-risk activities, such as routine plasmid transfection of established mammalian cell lines, non-replicating reporter constructs, and comparable BSL-1 activities.

I am also concerned about the provision extending the policy to non-NIH-funded research conducted at institutions that receive NIH funding. As written, NIH requirements would effectively become the institutional biosafety framework for covered research regardless of funding source. This may be reasonable for research involving substantial biohazards, but NIH should consider providing institutions greater flexibility for unrelated, low-risk, non-NIH-funded work.

The overall principle should be that scope follows meaningful biosafety risk, rather than simply whether an experiment meets a broad technical definition of genetic modification.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I strongly support the concept of tiered oversight. Federal review should be reserved for research involving substantial uncertainty or potentially significant consequences, while institutions and IBCs should retain

responsibility for routine risk assessment and local oversight.

The proposed distinction among research requiring NIH and IBC approval, full IBC review, and delegated IBC review is a useful framework. However, the lowest-risk tier should be made substantially more streamlined.

For example, the draft places well-characterized cell lines, plasmids, replication-incompetent non-integrating viral vectors expressing low-risk transgenes, and certain other low-risk work into a delegated-review pathway. Although preferable to full committee review, delegated review still requires submission, review, documentation, tracking, and renewal. At institutions conducting large amounts of molecular and cell biology, this could result in substantial administrative workload without a corresponding increase in biosafety.

I recommend adding an additional category for activities that require only institutional registration or notification, rather than formal approval. Such a pathway could include clearly defined routine BSL-1 and low-risk BSL-2 activities.

Federal review should remain focused on research involving novel, emerging, zoonotic, RG3/RG4, gene-drive, or otherwise uncertain hazards where national consistency and specialized expertise are necessary. Local IBCs are better positioned to evaluate routine work because they understand the facilities, personnel, training, and institutional context.

Tiering will be successful only if each tier represents a meaningful difference in administrative burden as well as a difference in risk.

3. Continued utility of Risk Groups: Risk Groups remain useful as a starting point for characterizing the inherent properties of a biological agent, but they should not be treated as equivalent to Biosafety Levels or used by themselves to determine containment.

I strongly support the draft policy's recognition that RG and BSL are related but distinct concepts. RG classification reflects properties of the agent, while appropriate BSL depends on the actual experiment, including genetic modifications, volume, aerosol generation, use of sharps, routes of exposure, animal procedures, and other manipulations.
This distinction becomes particularly important for genetically modified agents. A modification may increase risk by changing host range, transmissibility, pathogenicity, stability, or other biological properties, but it may also reduce risk through attenuation or replication deficiency. Therefore, neither the parent-agent RG nor a fixed BSL assignment should substitute for experiment-specific risk assessment.

I recommend retaining RGs as a baseline descriptor while using BSL/ABSL as the outcome of a comprehensive risk assessment. NIH should provide clear examples illustrating situations in which genetic modification or experimental manipulation appropriately raises or lowers containment relative to the baseline RG.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary adoption by making the policy practical, scalable, and clearly proportional to risk rather than by attempting to reproduce the full administrative structure required of NIH-funded institutions.

The most effective mechanism would be a set of freely available model resources that institutions can adopt in whole or in part. These could include standardized risk-assessment tools, model biosafety procedures, training materials, incident-reporting guidance, template IBC procedures, and simplified pathways for low-risk research.

A tiered voluntary framework would be especially useful for smaller institutions that may not have extensive biosafety infrastructure. For example, NIH could provide a basic framework for institutions conducting only BSL-1 and BSL-2 work and a more extensive framework for institutions conducting higher-risk research.

NIH should also promote access to regional or external biosafety expertise for institutions that do not maintain a full internal biosafety program.

Voluntary compliance will be more successful if institutions perceive the policy as a useful safety framework rather than as an administratively burdensome compliance system. NIH should therefore emphasize technical assistance, model resources, training, and incentives for adoption rather than enforcement-oriented mechanisms for institutions outside the formal scope of the policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident-reporting and transparency provisions require careful balance. Serious incidents involving laboratory-acquired infection, meaningful loss of containment, environmental release, or potential community risk should clearly be documented and, where appropriate, made public.

However, broad public posting requirements for lower-level incidents could unintentionally discourage reporting. A strong biosafety culture depends on investigators, students, and staff being willing to report mistakes, near-misses, minor exposures, and procedural failures promptly. If individuals believe that every reported event may ultimately become part of a publicly accessible institutional record, there is a risk of creating incentives for under-reporting.

The draft itself recognizes the value of protected reporting by proposing confidential, de-identified submission of near-misses and other safety information to the National Biosafety Data and Safety Analysis Center. I encourage NIH to apply the same principle more broadly.

I recommend distinguishing among:

serious reportable incidents that warrant NIH notification and public transparency;
lower-risk incidents that require institutional review but not public posting; and
near-misses that should be encouraged through confidential, non-punitive reporting systems.

The templates should also minimize collection and disclosure of personally identifiable information and

should focus on the nature of the hazard, circumstances of the event, corrective actions, and lessons learned.

For meeting minutes, transparency is appropriate, but templates should avoid requiring unnecessary technical detail that could disclose confidential research information, security-sensitive information, or details that do not contribute meaningfully to public understanding of biosafety oversight.

The goal should be transparency that improves safety and accountability without undermining reporting culture.

6. Other feedback relevant to this resource: Implementation guidance will be critical because the proposed policy substantially expands both the scope of covered research and the responsibilities of institutions, IBCs, and investigators.

NIH should provide detailed guidance in several areas.

First, NIH should provide concrete examples distinguishing research requiring full IBC review, delegated review, registration-only oversight if such a category is adopted, and activities outside the scope of the policy. Routine examples from molecular and cell biology would be particularly valuable, including plasmid transfection, CRISPR-modified mammalian cell lines, stable and transient expression, replication-deficient viral vectors, reporter constructs, primary cells, and established cell lines.

Second, NIH should provide decision trees or risk-assessment tools that allow investigators and IBCs to determine the appropriate level of oversight and containment consistently.

Third, additional guidance is needed on how genetic modification should influence risk assessment, particularly when modifications attenuate rather than increase risk.

Fourth, NIH should clearly distinguish PI responsibilities from institutional responsibilities. Investigators should be responsible for appropriate conduct, training, supervision, risk assessment, and reporting. However, responsibility for institutional infrastructure, certification and maintenance of containment equipment, occupational health programs, and institutional safety systems should remain clearly assigned to the institution. The current draft assigns a broad range of responsibilities to PIs that could benefit from greater clarification.

Fifth, NIH should provide clear guidance on what constitutes a change requiring prior IBC review versus a minor modification that does not materially alter risk.

Finally, implementation resources should be designed with institutions of different sizes and research intensities in mind. A framework that works for an institution with extensive BSL-3 infrastructure may impose unnecessary burden on an institution conducting primarily BSL-1 and routine BSL-2 molecular and cell biology.

Overall, implementation guidance should reinforce the central principle that the degree of oversight and administrative burden should be proportional to the actual biosafety risk of the research.

6. Other feedback relevant to this resource: Given the intention to shift focus away from "red-tape" and to real risks, I am very surprised by a few things that now are no longer exempt from needing IBC review.

To now require the use of previously generated transgenic rodents to now be submitted to the IBC significantly increases the administrative burden on the PI, biosafety staff, and whichever committee member is delegated with no real benefit. Biosecurity (animal escape) is a consideration of the IACUC. I would argue you went the wrong way as I would have exempted purchase of all transgenic vertebrates (but I do appreciate the other animals now can be delegated rather than going to a meeting).

Also, it is unclear to me whether a human research protocol that involves a human blood draw now needs to go to a convened meeting (it seems to meet the definition of primary cells that could be contaminated by adventitious agents). That is a vast percentage of human studies and to make them go to a meeting seems to create a huge administrative burden when the OSHA bloodborne pathogen standard already prescribes precautions that must be in place.

I also don't know how we're going to keep track of every plasmid used in E. coli. Delegated member review is still a lot of regulation added where it wasn't before.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Two incongruities in the tiered oversight are as follows:
- research involving genetically modified cells. It would be appropriate to differentiate research using previously modified cells (e.g. stable expressing cell lines) that are better placed in IV-3 than in IV-4 from generation of new genetically modified cells.
- similarly, genetic modifications of RG-2 pathogens that *decreases* virulence but still handled at BSL-2 would be more naturally placed with IV-4 than IV-3.
Implementing both of these changes would both give more consistent risk classifications and would incentivize institutions and investigators towards lower-risk activities when those are feasible (e.g. re-using previously generated cell lines and working with attenuated pathogens).

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The scope of public disclosure of research details before the research even begins has broad implications for both intellectual property and biosecurity. Public disclosure means that these can be scraped by AI agents by commercial and military adversaries of the United States and thus an incredibly granular picture of early-stage research will be obtained. This could be used to readily analyze and pre-empt NIH-funded research of commercial interest and also to target adversarial actions against the United States. Public reporting should be redacted and aggregated. There are two sets of concerns here - one is the United States public's interest in transparency. This would naturally focus on higher-risk research that carries risks for the public. This also has greater potential for non-commercial adversarial exposure (bioterror attacks, for instance). That is a trickier balance. For research that is low-risk to the public, the primary risks involve exposure of commercial information, either individually or at a large scale, that could be used both within the United States and, of particular national concern, by international commercial adversaries.

With the proposed disclosure, it would be easy to ask an AI agent "In what buildings and rooms are samples of virus X stored in city Y" or "analyze the disclosed activities of institution X and predict 10 future patent filings".

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: In the "Purpose; Background" section, it is stated "The feedback received to date has informed a new policy proposal that expands the scope of the NIH Guidelines to all biohazards while removing red tape for low-risk research," however, the new policy actually creates a truly significant amount of red tape for low-risk research in doing away with exemptions in Section III-F and Appendix C.
The draft policy lacks a category for exempt recombinant material, and therefore E. coli and S. cerevisiae protein expression experiments and work with previously exempt, commercially available transgenic rodents both read as explicitly included in Section IV-3, Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members.
If I'm not mistaken, this additional oversight represents a massive workload expansion, and the administrative burden is not commensurate with the risks of the research.
I urge the policy makers to re-implement the exemptions that were provided by Section III-F and Appendix C of the NIH Guidelines.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: In the "Purpose; Background" section, it is stated "... NIH also seeks to strengthen the role of Institutional Biosafety Committees (IBCs) and reinforce consistency with Institutional Review Boards and Institutional Animal Care and Use Committees, which serve as three foundational pillars of institutional oversight of biomedical research."

By raising the incident reporting thresh hold to BSL3/ABSL3, the draft policy actually disempowers IBCs at institutions that do not have high containment research.

Incidents incurred during research containable at BSL2/ABSL2 ought to continue to be reportable to NIH.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: The continued use of risk groups as a baseline for the risk assessment is absolutely needed. Although they often coincide, there is a difference between the risks of exposure to an organism and the containment level assigned to perform specific procedures using the organism. Referring to biosafety levels to describe organisms causes confusion when that containment level needs to be raised or lowered due to the procedures being used when a non-pathogenic strain is used. Additionally, it is important for people to understand the risks of exposure to an organism. If the "rules" of determining the risk groups are maintained, saying that an organism means a very specific thing; similar to how saying that you need to use BSL-2 containment invokes several requirements related to PPE and facilities.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Meeting Minutes Template: The template is not clearly organized, and although it references sections of the Policy, those Policy sections do not match the required information in the minutes template notes column (e.g., inspections in Section III-B). Some of the sections that appear to be required for every meeting should instead be included as items to consider as "Other Business". Some examples
A. The template starts providing requirements for application reviews/discussions. But in the middle of what should be a discussion on a specific application, the template says you should record discussion of any delegated review approvals?
B. There is a section for "inspections/ongoing oversight". According to the [policy, the BSO is only required for BSL-3 and GDMO applications. So, is this only for those inspections? The Policy states that the IBC is responsible for reviewing the facilities. There are many ways, outside of an inspection, that the members can review the facilities as they relate to the work proposed, while allowing EHS to handle lab inspections outside of the IBC process and schedule.

C. IBC Training: Is the IBC expected to receive training every time they meet? If not, this should be part of "Other Business".

Incident Reporting: Requiring all incidents to be posted online will completely undo all efforts made to have cultures of safety and reporting between researchers and administrators, EHS, and occ. health when an accident occurs. Especially in academic institutions where students are involved with research. It has taken years of building trust, and helping researchers understand that reporting incidents is not for punitive measures, but to make sure that they are OK, and that the people, animals, and environment around them are OK, as a result of what has happened. And that review of what happened and updating related processes and procedures helps to mitigate future occurrences. Posting every incident online will be viewed, especially by students, as 100% punitive, and will ultimately result in people having incidents occur that go unreported because they didn't want it posted online. Keeping names out of the online publication is not enough to stop this from happening. I understand the need for transparency and would understand having to publish incidents that were risky enough they required submission to NIH, but publishing every incident online is the best way to cause issues that could have been contained or treated before they become disasters, become disasters.

6. Other feedback relevant to this resource: The Policy mentions GDMO several times, but that acronym is not defined anywhere (unless you are familiar with the NIH Guidelines). This needs to be included in the definitions.

The Policy references risk groups and mentions that the BMBL is a resource for determining risk groups. The BMBL does not have risk group lists. It mentions risk groups of some agents, but mostly references the NIH Guidelines appendices to obtain that information. Where will the currently assigned risk group determinations "live" when the NIH Guidelines cease to exist? The risk groups are an excellent base assessment and educational tool, and should not be dropped. But a reputable and trustworthy resource/website is needed, and needs to be referenced in the Policy.

21. Yefrenia Henriquez Taveras

I am responding: On behalf of myself

Name: Yefrenia Henriquez Taveras

Name of Organization: Weill Cornell Medicine

Type of Organization: Academic Institution

Role: Other

Role - Other: Research Compliance Administrator

Date Submitted: 8/27/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical research across multiple disciplines, including gene therapy, virology, and translational research.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: This is a substantial expansion of IBC jurisdiction. Many IBCs are currently staffed, trained, and resourced around rDNA and gene transfer review. Extending IBC review to all wild-type biological agent research, including agents already subject to overlapping oversight (institutional biosafety officers, occupational health programs, and in some cases the Federal Select Agent Program), will require institutions to substantially rebuild committee composition, agenda capacity, and administrative infrastructure well in advance of the proposed six-month effective date.

I recommend that NIH: (a) provide a transition period longer than six months for research newly brought into scope solely by the expanded biohazard definition, distinct from research already subject to the current Guidelines; and (b) clarify how this Policy's oversight is intended to interact with, rather than duplicate, existing institutional biosafety programs governed by OSHA bloodborne pathogen standards, the Federal Select Agent Program, and institutional occupational health services, particularly for wild-type agent research with no genetic modification component.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Section V-E acknowledges that RG and BSL are related but not equivalent, and that the appropriate BSL for a given experiment may be higher or lower than the RG of the source agent depending on genetic modification and manipulation. However, the Policy does not provide a decision framework for resolving this determination consistently across institutions.

In practice, this ambiguity falls to individual IBCs to resolve, which will produce inconsistent containment determinations for functionally similar constructs across institutions, undermining one of the Policy's stated goals of harmonized, transparent oversight. This is most acute for the multi-source construct scenario addressed in Section V-C, where an IBC must weigh RG classification, encoded function, and synergistic effect without a specified method for arriving at a final containment determination.

I recommend that NIH develop and publish, as part of the implementation resources referenced in the Policy, a structured decision tool or worked examples illustrating how RG classification, genetic modification, and manipulation risk are to be weighted against one another in arriving at a BSL determination, particularly for GDMO and synthetic construct research.

3. Continued utility of Risk Groups: Neither the current Guidelines nor this draft defines "surrounding community" by geography, and NIH has historically interpreted the phrase narrowly to require that non-affiliated members reside in or near the institution's local community. This interpretation has already led institutions to construct workaround arrangements, such as multi-institution reciprocal IBC agreements limited to geographically clustered institutions, in order to share qualified non-affiliated members rather than each recruiting independently.

As NIH is now modernizing the Policy and substantially expanding IBC jurisdiction to cover all biohazards, this is a natural opportunity to resolve the ambiguity rather than carry it forward unchanged. Institutions outside major research hubs, or those with multiple affiliated sites, face genuine difficulty recruiting qualified non-affiliated members under a strict local-residency reading, and the expanded scope of research subject to IBC review under this Policy will increase, not decrease, the demand on this pool of members.

I recommend that NIH either define "surrounding community" with explicit flexibility (for example, permitting non-affiliated members who reside within a defined regional area rather than strict local proximity), or expressly authorize multi-institution reliance arrangements for shared non-affiliated membership, particularly for institutions that are geographically proximate or under common administration.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Institutions that operate mixed research portfolios, including non-NIH-funded programs or affiliated entities that do not themselves receive NIH funds, have little practical basis for extending IBC oversight to those programs absent a defined mechanism.

I recommend that NIH consider concrete measures to support voluntary adoption, such as a public registry or attestation process for institutions extending Policy-consistent oversight to non-covered research, or guidance addressing how institutions may apply a single IBC review process across covered and non-covered research without creating inconsistent administrative records.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The Draft Incident Reporting Template instructs institutions not to include attachments, while Part 3 of the template calls for narrative detail sufficient to reconstruct the timeline, root cause, equipment or facility failures, and personal protective equipment performance associated with the incident. For incidents involving equipment failure or complex root cause analysis, supporting documentation (equipment logs, inspection records, laboratory diagrams) is often necessary to substantiate the narrative and support NIH's review, but the template as drafted precludes submitting it.

I recommend that NIH either permit limited supporting attachments for final reports (as distinct from initial 24-hour notifications), or clarify that institutions may reference underlying documentation

retained on file and available to NIH upon request, rather than requiring all substantiating detail to be captured in narrative form alone.

6. Other feedback relevant to this resource: NIH has indicated it will publish implementation resources addressing IBC functions, gene drive modified organism biosafety considerations, Risk Group classifications, and RG3 influenza-specific requirements. Two additional areas warrant implementation guidance given the Policy's scope:

First, Sections III-D and IV-1 direct institutions to petition NIH for containment determinations involving emerging, novel, or zoonotic agents without an available RG classification, and for initial requests to lower containment for RG3 or RG4 agents or GDMOs. The Policy states that NIH will review such requests "in a timely manner" but specifies no target turnaround. Because research subject to Section IV-1 cannot begin until NIH acts, an undefined review timeline creates planning uncertainty for institutions and investigators, particularly for time-sensitive or externally funded research. I recommend that NIH publish target review timeframes for Section IV-1 determinations, distinguishing routine requests from those requiring novel scientific assessment.

Second, Section III-A requires institutions to submit a written Biosafety Assurance approved by NIH before conducting any research subject to the Policy, renewable for periods of up to four years. The Policy does not describe a submission format, portal, or review timeline for this Assurance, unlike the Federalwide Assurance process OHRP has long maintained for human subjects research. Because the Policy's expanded scope will require many institutions to submit an Assurance for the first time, I recommend that NIH publish, as an implementation resource, a defined Assurance submission mechanism and an expected review timeline comparable to the OHRP FWA process.

22. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

23. Kathleen George

I am responding: On behalf of myself

Name: Kathleen George

Name of Organization: WCG

Type of Organization: Commercial Entity (Biotech/Device/Pharmaceutical Company/Small Business)

Role: Institutional Review Oversight Committee Member

Date Submitted: 9/1/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): human gene therapy clinical trials

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Period of IBC oversight. The update states that oversight may conclude after the last participant is administered the final dose. For clinical trials, the study agent is often present at the institution for a long time after last dose. The site will need send the agent back to the sponsor or dispose of it at the site. Storage, transport, and biohazard waste management should still be reviewed by the IBC until the agent is no longer at the institution.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I wasn't aware of NIH biosafety education until I read about it in the update. I think its great that NIH provides biosafety education, however, the education should be more prominently promoted so biosafety personnel are aware of its existence.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

24. Anna McLoon

I am responding: On behalf of myself

Name: Anna McLoon

Name of Organization: Siena University

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 9/1/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Molecular microbiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Hello,

I am a member of the IBC at Siena, and I am confused about how to apply the updated guidelines to these situations:

1. What about work with organisms like Bacillus subtilis or Saccharomyces cerevisiae that are generally recognized as safe? These do not meet the definition of "biological agent" so does that mean work with GRAS organisms are exempt from oversight? Or does any project with transgenic yeast or Bacillus subtilis require approval before initiation?

2. All language here is focused on research, but across the country, recombinant DNA, genetically modified animals like fruit flies, and biological agents are often used in teaching laboratories. What are expectations about registration and oversight of projects that are carried out in the teaching laboratory? These do not fit under the definition of research. Do ALL teaching exercises require individual approval, or are they not covered by the guidelines intentionally?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Are the new policies purposely getting rid of the category that previously just required submission at the time of initiation? This is unclear.

For smaller, teaching focused institutions, these guidelines are a bit hard to interpret in terms of how much oversight is needed for basic-science research or teaching laboratory activities with organisms with

no real threat to researcher or community (GFP expressing zebrafish, gene knockout strains of yeast, etc.). More guidance about low-risk cases would be helpful, especially any ways to simplify the process for educators and researchers, which will help increase understanding and compliance.

25. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Date Submitted: 9/2/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): University of Missouri-Kansas City

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The expanded scope : from recombinant/synthetic nucleic acid molecules to any biomedical research involving wild-type human pathogens, genetically modified organisms, toxins/prions, or agents containing these, represents a substantial broadening of institutional oversight responsibility. While closing genuine gaps (e.g., wild-type pathogen work that previously fell outside IBC purview) is a reasonable goal, the definition as drafted creates ambiguity that will produce inconsistent institutional interpretation:

The phrase "known or potential risk to human health" is not quantified or bounded. Institutions need clearer thresholds (e.g., does BSL-1 wild-type work with no meaningful pathogenicity in immunocompetent hosts fall under the policy, or only agents with a defined risk group designation?). "Self-aggregating proteins" as a category alongside toxins and prions is vague, this could sweep in basic protein-folding research never intended for biosafety oversight. NIH should provide a non-exhaustive list of covered agent classes or a decision-tree tool.
There is no explicit treatment of in vitro diagnostic reagents, environmental/wastewater surveillance samples, or clinical specimens of unknown infectious status, all of which are common in academic biomedical research and sit in a gray zone under the proposed definition.
We recommend NIH clarify whether human cell lines or patient-derived samples that are not genetically modified but carry endogenous or adventitious agents (e.g., primary tissue with unknown viral status) fall within scope, since "cells... that have been genetically modified" is explicit but non-modified but potentially infectious samples are not addressed.

Without this clarification, institutions will apply inconsistent scoping determinations, undermining the goal of national consistency this policy is meant to achieve.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The general direction; delegating more RG2-level containment decisions to the IBC while retaining NIH review for RG3/RG4, is appropriately risk-calibrated in principle. However, several elements of the tiering warrant reconsideration:

Local IBCs vary widely in technical capacity and available expertise across institutions of different sizes. A tiering scheme that assumes uniform IBC sophistication nationally risks inconsistent risk management at smaller or resource-limited institutions that lack in-house biosafety expertise to responsibly exercise newly delegated authority (e.g., approving containment reductions or exercising delegated review) without an NIH backstop.

The tiering of incident reporting (NIH-reportable vs. institution-only) is a reasonable federal/local split for genuinely low-risk events, but the criteria for the local tier (e.g., "agent-specific treatment beyond basic first aid") require more precise, auditable definitions to prevent under-reporting or inconsistent classification across institutions

3. Continued utility of Risk Groups: Risk Groups remain a useful baseline for intrinsic agent hazard (transmissibility, severity, availability of treatment) but are increasingly poor proxies for actual risk once genetic modification is introduced. We recommend the following:

RG classifications are typically assigned to wild-type organisms and do not automatically capture risk changes from genetic modification (e.g., host range expansion, enhanced transmissibility, altered virulence, or novel gain-of-function characteristics). The policy should require an explicit, documented risk reassessment for any genetically modified derivative of an RG-classified agent, rather than allowing the parental RG designation to be inherited by default.

BSL/ABSL, by contrast, reflects the containment and practice controls actually applied to mitigate risk in a given experimental context, and is a more operationally meaningful metric for day-to-day IBC and reporting purposes (as reflected in the incident-reporting tiers, which are BSL-based, not RG-based).

The final policy should explicitly state that RG is a starting point for hazard identification, not a substitute for a documented, agent- and modification-specific risk assessment, and that containment decisions (BSL/ABSL) must be justified by that assessment rather than derived mechanically from RG. This is particularly important for the newly delegated review categories (e.g., "RG1 genetically modified biological agents"), where a low starting RG could mask a significant risk change introduced by the modification itself.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Because the Policy remains a term and condition of NIH award (not a general regulatory requirement), non-NIH-funded entities conducting comparable biohazard research have no obligation to comply, creating an uneven national biosafety landscape. To encourage voluntary adoption:

NIH could develop a formal "recognition" or attestation program allowing non-federally-funded institutions to publicly certify adherence to the Policy, which would carry reputational and partnership value (e.g., for institutions seeking to collaborate with NIH-funded partners or attract sponsored research).

NIH could tie eligibility for future funding mechanisms, training grants, or NIH-sponsored biosafety resources (e.g., the mandated templates, technical assistance) to demonstrated voluntary compliance,

creating an incentive short of a funding mandate.

Providing the compliance templates, training materials, and model assurance language freely and prominently (not gated behind an active award) would lower the barrier for non-funded institutions to adopt the framework voluntarily, particularly smaller institutions without the administrative capacity to build a compliance program from scratch.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting template should include a clearly delineated field for the reporting tier determination (NIH-reportable vs. institution-only) with the specific criterion cited, to create an auditable record of why an incident was or was not escalated to NIH, this supports consistency review and reduces ambiguity in borderline cases.

The incident template should include a structured field for corrective action and follow-up verification, distinct from the initial incident description, so that both NIH and the public (given the new public-posting requirement) can see resolution status, not just the initial event.

The mandated meeting minutes template should accommodate institution-specific business (e.g., local policy items unrelated to federal reporting) as an optional addendum section, rather than forcing all IBC business into a federally-defined structure. Without this flexibility, institutions may end up maintaining two sets of minutes (one for federal compliance, one for internal governance), duplicating administrative effort.

Both templates should be released in an editable, structured electronic format (not PDF) compatible with common IBC/protocol management software, to avoid a costly manual re-entry burden across institutions transitioning from existing systems.

6. Other feedback relevant to this resource: This is my most significant concern with the draft as a whole, and I urge NIH to address it before finalization.

The Policy's requirement that all incidents : including those that remain institution-only and never reach NIH, be posted to a public-facing institutional website represents a substantial departure from current practice, where only NIH-reportable incidents are subject to public disclosure (via FOIA request, which involves a review and redaction process). We are concerned this requirement, as drafted, will have the opposite of its intended effect:

Chilling effect on self-reporting. Laboratory personnel are the first line of incident identification. If staff know that even minor, appropriately-managed events (e.g., a needlestick with only first-aid treatment, an animal bite) will be published publicly and potentially attributable to their lab or specific personnel, institutions should reasonably expect a decline in voluntary self-reporting, the opposite of the transparency and safety-culture goals the policy intends to advance. Underreporting of "minor" events is also how institutions typically identify systemic or trending risks before they escalate; suppressing that data pipeline undermines proactive safety management.

Absence of privacy/redaction standards. The draft does not specify what level of detail must be publicly posted, whether personally identifiable information (employee names, specific lab locations, treatment

details) must be redacted, or who is responsible for reviewing postings for privacy and legal compliance before publication. Without this guidance, institutions face genuine legal exposure (potential HIPAA-adjacent issues, workers' compensation implications, and defamation/privacy tort risk) and will likely respond by either over-redacting postings to the point of uselessness or, more likely, under-reporting or delaying disclosure while legal review occurs, undermining the timeliness the policy seeks.

No defined retention or format standard. The draft does not specify how long postings must remain public, whether they must be updated as investigations conclude, or in what format (searchable log vs. static PDF) they must appear, this ambiguity will produce widely inconsistent public transparency across institutions, undermining comparability.
Recommendation: NIH either (a) limit the public-posting requirement to incidents that meet the NIH-reportable threshold, consistent with current FOIA-based public availability, and allow institution-only incidents to remain within existing institutional safety/HR reporting channels; or (b) if public posting of all incidents is retained, issue detailed guidance on required redaction standards, a standardized aggregate/de-identified reporting format (e.g., annual summary statistics rather than incident-level detail for the lowest tier), and a defined review and retention process, developed in consultation with institutional legal counsel, biosafety officers, and IBC chairs before finalization, given the direct tension between public transparency and the self-reporting behavior the biosafety oversight system depends on.

Additional implementation guidance would also be valuable on: (1) a model SOP or decision criteria for delegated review to promote consistency across institutions exercising this new authority for the first time; (2) clarification of the "higher risk manipulations" threshold referenced for clinical research triggers; and (3) a transition timeline and grace period for institutions to complete the scope-gap analysis, revise IBC charters, and build new public-reporting infrastructure before enforcement begins.

26. Shubhashish Sarkar

I am responding: On behalf of myself

Name: Shubhashish Sarkar

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 9/3/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): All types of biomedical research.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The inclusion of wild type organisms for biosafety oversight is a right step taken by NIH and is much appreciated. This will be beneficial to safeguard the researchers and the environment. However, the policy gives a vague approach towards identifying the dangerous organism that will need a biosafety oversight. It is difficult to understand who will decide the pathogenicity of any organism an investigator wants to use in research. Will NIH revise the existing databases or create a totally new database with additional organisms.
The policy has emphasized genetic modification of any kind that will result in pathogenicity of an organism or vice versa. However, changes in growth conditions or other environmental factors are also associated with pathogenicity of an organism (Fierer J, Looney D, Pechère JC. Nature and Pathogenicity of Micro-organisms. Infectious Diseases. 2017:4–25.e1. doi: 10.1016/B978-0-7020-6285-8.00002-2. Epub 2016 Aug 12. PMCID: PMC7173513.). Are these exempted modifications ignored?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

27. Jennifer Hill

I am responding: On behalf of myself

Name: Jennifer Hill

Name of Organization:

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 9/3/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am concerned that the proposed scope would unintentionally bring substantial amounts of routine, low-risk biomedical research under IBC oversight without a corresponding biosafety benefit. One example is the proposed requirement for review and approval of research conducted with transgenic organisms at BSL-1/ABSL-1. This appears to encompass routine use of established genetically modified mouse lines, including commercially available Cre, floxed, knockout, and reporter strains that have been developed, characterized, and widely used by the research community. In most experiments, the genetic modification does not itself create a meaningful biosafety hazard. A laboratory may purchase an established transgenic mouse line and use it to study normal physiology, metabolism, behavior, or responses to pharmacologic treatments. Requiring IBC approval solely because the animal carries a defined genetic modification would add another regulatory layer to studies that may present no greater biosafety risk than comparable experiments in wild-type animals.

I encourage NIH to retain an exemption or establish a categorical exclusion for established transgenic rodent lines maintained and used at ABSL-1 when the genetic modification does not reasonably increase risk to human health or the environment. IBC oversight would be more appropriately focused on genetic modifications that materially alter pathogenicity, toxicity, transmissibility, environmental persistence, host range, or another characteristic relevant to biosafety.

I am also concerned that the proposed definition of "toxin" is broad enough to encompass ordinary endogenous proteins and peptide hormones. The draft defines a toxin as a "protein or peptide produced by living organisms that causes harm in humans." Taken literally, this could include insulin, since insulin is a naturally produced peptide hormone and inappropriate exposure or administration can cause severe hypoglycemia. The same ambiguity could extend to other peptide hormones, cytokines, growth factors, and physiological signaling molecules. It seems unlikely that routine administration of insulin in an animal physiology experiment is the type of biological-toxin research NIH intends to place under IBC oversight, but the proposed definition does not clearly exclude it.

I recommend revising the definition of toxin so that it clearly distinguishes recognized biological toxins from endogenous proteins, peptide hormones, cytokines, growth factors, and similar physiological molecules used in routine biomedical research. The definition should focus on inherent toxic activity or established biosafety classifications rather than simply whether a protein or peptide can cause harm under some exposure condition.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed use of delegated IBC review for lower-risk research is a useful mechanism for reducing burden, but delegated review does not fully address the underlying problem if very low-risk activities are unnecessarily brought within the policy in the first place. Routine use of an established ABSL-1 transgenic mouse line should not require IBC approval simply because the animal is genetically modified when the modification has no plausible effect on biosafety risk.

A risk-calibrated system should distinguish between research that warrants oversight and research that is sufficiently low risk to be categorically excluded. Delegated review is appropriate for research that presents a low but non-negligible biosafety risk. It should not substitute for an exemption where there is no meaningful biohazard to assess. NIH should therefore consider explicit exclusions for established ABSL-1 transgenic rodent lines whose genetic modifications do not increase biosafety risk, while retaining IBC review for modifications that alter characteristics relevant to human, animal, or environmental safety.

3. Continued utility of Risk Groups: Risk Groups and Biosafety Levels remain useful frameworks for biological agents for which pathogenicity, transmissibility, routes of exposure, and containment are meaningful considerations. However, neither framework by itself resolves the problem of applying biosafety oversight to routine genetically modified animals or physiological proteins that do not present hazards analogous to infectious agents.

For these categories, the risk assessment should focus on whether the particular genetic modification, protein, or experimental manipulation actually changes the risk of harm to research personnel, the public, or the environment. The mere presence of a genetic modification in an ABSL-1 mouse should not itself be treated as evidence of increased biosafety risk.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed incident-reporting requirements could have unintended consequences when combined with the expansion of the policy to routine ABSL-1 transgenic animals. The draft identifies events such as bites, scratches, animal escapes, and improper disposition involving animals used in research subject to the policy as incidents requiring IBC review. If an ordinary commercially available transgenic mouse is now considered covered research solely because it is genetically modified, a routine mouse bite, scratch, or escape could become an IBC-reportable incident even when the genetic modification has no relationship to the risk posed by the event.

This could generate substantial administrative reporting of events that do not represent meaningful biosafety incidents. The requirement for public posting of finalized incident reports further increases the

consequences of classifying very low-risk events in this manner. NIH should distinguish incidents involving an actual biohazard from routine animal-handling events in which the covered characteristic of the animal did not contribute to the hazard. Incident reporting should be calibrated to the biological risk posed by the event rather than triggered solely because the animal happens to fall within the policy's broad scope.

6. Other feedback relevant to this resource: Additional guidance would be particularly valuable in several areas created by the expanded scope of the policy. NIH should clearly define which established transgenic rodent lines require IBC review and whether routine breeding, colony maintenance, and experiments involving commercially available Cre, floxed, knockout, and reporter lines are intended to be covered. NIH should also define what constitutes a "low-risk transgene" for purposes of delegated review of viral-vector research.

Most importantly, NIH should provide explicit guidance on the meaning of "toxin." The current wording could reasonably be interpreted to include endogenous peptide hormones such as insulin and potentially many other physiological proteins that can cause harm at sufficiently high doses. Implementation guidance should make clear whether such compounds are outside the intended scope. Preferably, this distinction should be incorporated directly into the policy definition rather than left solely to subsequent guidance, since inconsistent institutional interpretations could otherwise lead to substantial variation in IBC oversight.

NIH should also clarify how incident-reporting requirements apply to routine ABSL-1 transgenic animal research. If NIH intends standard transgenic rodent lines to remain within the policy, guidance should distinguish events that actually implicate the genetic modification or another biohazard from ordinary animal-handling incidents that pose no additional biosafety risk because the animal is transgenic.

28. Jenifer Coburn

I am responding: On behalf of myself

Name: Jenifer Coburn

Name of Organization: Medical College of Wisconsin

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 9/4/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): pathogenic microbiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I do not believe that it is appropriate to require public posting of Institutional Biosafety Committee (IBC) members' names. This is due to concerns regarding some members of the public targeting individuals at work and/or at home. These sorts of attacks may be rare but the population of those who believe that this is legitimate appears to be growing.

For the same reason, I do not believe that the Principal Investigator's name should appear in the IBC meeting minutes. I suggest that the PI's name be redacted. Laboratory personnel names should not be included in any public-facing document or website.

Why is genetic manipulation of plants not considered potentially risky to human health? Humans eat plants.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

29. Partha Krishnan

I am responding: On behalf of myself

Name: Partha Krishnan

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 9/4/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Recombinant DNA

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft expands coverage to include wild-type pathogens, genetically modified organisms, toxins, prions, and other biohazards, rather than focusing primarily on recombinant nucleic acid research. This better aligns oversight with contemporary synthetic biology, gene editing, and emerging pathogen research. Can the definition of biohazard be so broad to encompass any agent - living or dead of biological origin that causes a threat to the healthy human condition?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Institutions receiving NIH funding would be required to ensure compliance for all covered research conducted at their institution, regardless of funding source. The proposed Biosafety Assurance mechanism may improve institutional ownership of biosafety programs.

3. Enhanced Transparency

The requirement to publicly post IBC meeting minutes and incident reports could substantially improve public trust and enable cross-institutional learning from biosafety events

3. Continued utility of Risk Groups: Move toward a multi-factor risk framework including:

Agent characteristics
Modification type
Experimental procedures
Exposure potential
Scale of work
Environmental consequences
Availability of countermeasures

Benefit : Traditional RG classifications may not adequately capture risks from genetically modified or synthetic organisms.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Mandate Near-Miss Reporting
Issue :The policy emphasizes incidents but provides less clarity on systematic near-miss reporting.

Recommendation : Create tiered reporting requirements:

Near miss - Institutional database
Significant near miss- NIH database
Exposure/release - Immediate NIH notification

High-reliability industries (aviation, nuclear power) derive tremendous safety benefits from near-miss analysis before harm occurs.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting template is comprehensive and supports the policy goals of transparency and accountability. However, several enhancements could improve its value for institutional learning and national biosafety analysis.

1. Add Structured Near-Miss Reporting

Comment: The template focuses on reportable incidents but does not explicitly capture near misses.

Recommendation: Add a field:

Was this:
Incident
Potential exposure
Near miss
Unsafe condition

Rationale: Near misses provide some of the most valuable opportunities for prevention and are a cornerstone of high-reliability safety programs.

2. Strengthen Root Cause Analysis Requirements

The current template requests a root cause description and corrective actions.

Recommendation: Require categorization of root causes:

Human factors
Training deficiency
SOP deficiency
Equipment failure
Facility failure
Organizational/process failure

Communication failure
Risk assessment deficiency

Benefit: Facilitates trend analysis by the proposed National Biosafety Data and Safety Analysis Center.

3. Track Contributing Factors Separately

Recommendation: Add a section:

"Contributing Factors (check all that apply)"

Fatigue
Workload
Time pressure
Staffing shortage
Inexperience
Inadequate supervision
Equipment design
Environmental conditions
Other

Reason: Most incidents arise from multiple factors rather than a single root cause.

4. Add Risk Severity Classification

Recommendation:

Include:

Actual Consequence
No impact
Minor injury
Medical treatment
Laboratory-acquired infection
Environmental release
Potential Consequence
Negligible
Low
Moderate
High
Severe

Benefit: Improves national comparisons and prioritization of corrective actions.

5. Include Corrective Action Effectiveness Review

Currently, corrective actions are documented, but effectiveness is not evaluated.

Recommendation:

Add:

Responsible person
Implementation date
Verification method
Follow-up review date
Effectiveness assessment

This ensures corrective actions are not merely documented but validated.

6. Improve Biosecurity Capture

Recommendation:

Add specific fields addressing:

Inventory discrepancy
Unauthorized access
Security breach
Suspected misuse
Cybersecurity-related laboratory event

This would better integrate biosafety and biosecurity.

7. Clarify Public Transparency Expectations

The template appropriately promotes public transparency using lay language.

Recommendation:

Provide:

A public summary section (1-2 paragraphs)
A technical section for NIH review

This balances transparency with technical completeness.

Comments on Draft_IBC-Meeting-Minutes-Template.pdf

The template is thoughtfully designed and likely represents a major improvement in transparency. It should, however, provide additional structure to improve consistency across institutions.

1. Add a Safety Culture Review Section

Current minutes focus on protocol review and compliance activities.

Recommendation:

Include a standing agenda item:

Biosafety Program Metrics
Number of incidents
Number of near misses
Laboratory inspection findings
Training completion rates
Outstanding corrective actions

Benefit: Promotes proactive oversight rather than reactive incident review.

2. Require Documentation of Risk-Benefit Discussions

The template requests risk assessment discussion, but not the rationale for acceptability of risk.

Recommendation:

Add:

Risk-Benefit Rationale
Key risks identified
Mitigation measures
Scientific value
Reason risks were considered acceptable

This improves transparency and consistency.

3. Capture Emerging Technology Considerations

The broader biosafety policy explicitly addresses novel organisms and AI-enabled synthetic biology.

Recommendation:

Include a review prompt:

Emerging Technology Considerations
Synthetic biology
Gene editing
Gene drives
AI-assisted biological design
Novel organisms

Helps ensure consistent review of future technologies.

4. Improve Conflict of Interest Documentation

The template requires disclosure of conflicts but provides limited detail.

Recommendation:

Document:

Name of conflicted member
Nature of conflict (general category)
Recusal confirmed
Member absent during vote

This strengthens transparency.

5. Require Documentation of Containment Justification

The template records assigned biosafety levels.

Recommendation:

Add:

Containment Justification
Basis for containment selection
Deviations from standard guidance
Enhanced containment measures

This improves consistency and auditability.

6. Add Oversight Tracking Dashboard

For each meeting include:

Metric NumberActive protocols
New protocols reviewed
Amendments reviewed
Deferred reviews
Open incidents
Closed incidents
Conditional approvals

This enables institutions and NIH to identify trends over time.

7. Add Corrective Action Tracking

The current format discusses incidents and inspections but lacks formal tracking.

Recommendation:

Create a standing section:

Open Corrective Actions
Description
Responsible party
Due date
Status

This supports continuous improvement.

8. Clarify Redaction Standards

The template permits redaction of private, proprietary, or security-sensitive information while emphasizing transparency.

Recommendation:

NIH should publish:

Standard redaction guidance
Example acceptable redactions
Example unacceptable redactions

This would improve consistency across institutions.

6. Other feedback relevant to this resource: I am submitting a manuscript to Applied Biosafety with the abstract below for a NEW biosafety paradigm moving away from regulation based checklists

Abstract

Ensuring safe operation of research and clinical laboratories requires a structured, repeatable, and rapid method for assessing baseline safety conditions.2–5 Traditional inspections and audits, while essential, are often time intensive, episodic, and dependent on the expertise of individual reviewers.4,5,9,10 This creates variability in safety assessments and delays in identifying critical gaps. To address this challenge, a simplified, four domain scoring system designed to provide an immediate snapshot of facility safety readiness is proposed. The SAFE Score evaluates Signage, Awareness, Facility, and Emergency Equipment, assigning each a score from 0 to 2. The total score (0–8) functions as a “safety vital sign,” analogous to the APGAR score used in pediatrics to rapidly assess newborn health.1,6 Like APGAR, the SAFE Score is not a substitute for comprehensive evaluation but serves as a standardized, rapid triage tool that determines the urgency of intervention and guides next steps.1,6 This article presents the conceptual foundation, development, and application of the SAFE Score, explores its parallels with the APGAR framework, and demonstrates how it can transform laboratory safety culture by enabling consistent, data driven decision making.7,9,13

Draft of manuscript is attached.

Uploaded File: SAFE_Score_Research_Article_SAGE_Format.pdf

The SAFE Score: A Rapid, Standardized Framework for Assessing Laboratory Safety Readiness

Abstract

Ensuring safe operation of research and clinical laboratories requires a structured, repeatable, and rapid method for assessing baseline safety conditions.[2–5] Traditional inspections and audits, while essential, are often time-intensive, episodic, and dependent on the expertise of individual reviewers.[4,5,9,10] This creates variability in safety assessments and delays in identifying critical gaps. To address this challenge, a simplified, four-domain scoring system designed to provide an immediate snapshot of facility safety readiness is proposed. The SAFE Score evaluates Signage, Awareness, Facility, and Emergency Equipment, assigning each a score from 0 to 2. The total score (0–8) functions as a "safety vital sign," analogous to the APGAR score used in pediatrics to rapidly assess newborn health.[1,6] Like APGAR, the SAFE Score is not a substitute for comprehensive evaluation but serves as a standardized, rapid triage tool that determines the urgency of intervention and guides next steps.[1,6] This article presents the conceptual foundation, development, and application of the SAFE Score, explores its parallels with the APGAR framework, and demonstrates how it can transform laboratory safety culture by enabling consistent, data-driven decision-making.[7,9,13]

Introduction

Laboratory environments—academic, industrial, clinical, and commercial—are dynamic systems where people, procedures, equipment, and materials interact continuously. Safety in these settings is not a static achievement but an ongoing operational requirement that must be actively managed at every level of the organization. Engineering controls, administrative policies, and written procedures form the backbone of a safe laboratory, but they are effective only when paired with routine verification, clear communication, and a culture that prioritizes readiness. When any of these elements weaken—through staffing turnover, deferred maintenance, or simple human complacency—the probability of incidents rises, often in ways that are subtle and cumulative rather than dramatic and immediate.

Traditional safety programs rely heavily on formal audits, regulatory inspections, and incident investigations. These activities are indispensable for ensuring compliance and for uncovering systemic weaknesses, but they share common limitations: they are episodic, resource-intensive, and often scheduled far enough apart that small degradations can go unnoticed. An annual or semiannual audit can document compliance at a point in time without revealing the day-to-day drift that precedes many near misses and accidents. Moreover, audits frequently depend on the expertise and judgment of individual inspectors, which introduces variability in findings and in the prioritization of corrective actions. For organizations that operate multiple sites or diverse laboratory types, this variability complicates comparisons and obscures broader trends.

To address these gaps, safety programs need tools that are rapid, repeatable, and standardized tools that convert qualitative observations into quantitative signals that can be trended, compared, and acted upon. The SAFE Score proposed here as a framework meets that need. By condensing readiness into four universal domains—Signage, Awareness, Facility, and Emergency Equipment—and scoring each domain on a simple 0–2 scale, SAFE produces a single, interpretable metric that functions as a "safety vital sign." This metric is intentionally lightweight so it can be collected frequently by a range of observers, from EHS professionals to laboratory supervisors and trained frontline staff, without the need for lengthy checklists or specialized audit teams.

The design philosophy behind SAFE draws directly from successful rapid-assessment models in other high-risk fields. The APGAR score in neonatology is a paradigmatic example: a short, standardized assessment that does not replace comprehensive clinical evaluation but provides an immediate, reproducible trigger for intervention as to whether a newborn baby, minutes after birth, is adapting well to life outside of the womb. SAFE adopts the same architecture—few domains, simple scoring, and clear triage thresholds—so that a low score prompts predefined actions rather than protracted deliberation**.** This reduces the time between detection and remediation and embeds a culture of immediate, evidence-based response into routine operations.

Each SAFE domain was chosen for its universal relevance and its capacity to reveal early signs of degradation. **Signage** communicates hazards and controls; missing, illegible, or incorrect signs are often the first visible indicator of broader lapses in maintenance or oversight. **Awareness** captures the human dimension: whether personnel recognize hazards, know where to find controls, and can articulate basic response steps. Awareness deficits frequently precede unsafe behaviors even in well-equipped facilities. **Facility** assesses the presence and functionality of engineering controls—ventilation, containment devices, and certified equipment—that materially reduce exposure risk. Finally, **Emergency Equipment** evaluates whether eyewash stations, showers, fire suppression, spill kits, and other critical resources are present, accessible, and operational. Together these domains provide a balanced view of communication, human factors, infrastructure, and emergency readiness.

The practical advantages of a standardized, short-form tool are multiple. First, frequent SAFE assessments create a continuous data stream that enables trend analysis, early detection of seasonal or staffing-related patterns, and objective evaluation of interventions such as training or maintenance programs. Second, a numeric, color-coded output simplifies communication across organizational levels: a single dashboard can show which units are trending toward risk and which require immediate attention. Third, standardization reduces inter-rater variability and allows aggregation of results across sites, which is essential for organizations that must allocate limited EHS resources strategically.

At the same time, SAFE is explicitly designed to complement—not replace—formal audits and regulatory reviews. Short-form assessments are inherently reductive and cannot capture the full complexity of systems, documentation, and procedural compliance that comprehensive audits examine. To mitigate this limitation, SAFE should be integrated into a broader governance framework that includes periodic comprehensive audits, cross-audits for calibration, and

mechanisms for verifying the accuracy of routine assessments. Training, inter-rater reliability checks, and periodic recalibration of scoring criteria are essential to maintain the tool's validity and usefulness.

Finally, the cultural implications of adopting a tool like SAFE are significant. When safety readiness is measured frequently and communicated clearly, it becomes part of everyday work rather than an occasional administrative burden. A simple, repeatable metric empowers frontline staff to participate in safety monitoring, creates transparent accountability, and fosters a proactive approach to risk reduction. In an era of increasing laboratory complexity, staffing pressures, and regulatory scrutiny, embedding rapid, standardized readiness checks into routine practice offers a pragmatic path to more resilient, safer laboratory operations.

Background and Rationale

Laboratory safety is an ongoing operational requirement, not a one-time compliance exercise. Traditional audits and regulatory inspections are essential but episodic, resource-intensive, and subject to inter-inspector variability, which limits their ability to detect early drift in day-to-day readiness. Standardized, short-form assessments convert sporadic checks into continuous monitoring, enabling organizations to detect small but consequential degradations (e.g., faded signage, uninspected eyewash stations, or lapses in personnel awareness) before they escalate into incidents. Frequent, standardized checks also create comparable data streams that support statistical monitoring, targeted interventions, and evidence-based resource allocation.

The SAFE Score operationalizes these principles by reducing laboratory readiness to four universal domains—Signage, Awareness, Facility, and Emergency Equipment—each scored 0–2**,** producing a single 0–8 metric that is easy to record, interpret, and trend. The SAFE Score provides a rapid, structured, and standardized method for assessing laboratory safety readiness. By evaluating four essential domains—Signage, Awareness, Facility, and Emergency Equipment—the SAFE Score enables organizations to identify gaps early, track trends over time, and cultivate a proactive safety culture.

Why mirror APGAR? The APGAR score's enduring utility in neonatology stems from five attributes: simplicity, universal applicability, rapid execution, reproducible scoring, and direct linkage to immediate actions. APGAR's 0–2 per-item scale and clear triage thresholds trained clinicians to act quickly and consistently; it did not replace comprehensive neonatal assessment but provided a standardized trigger for urgent intervention. Adopting the same architecture for laboratory safety means a low SAFE Score triggers predefined escalation steps rather than subjective debate, shortening the time from detection to remediation and embedding safety triage into routine workflows.

Standardization reduces variability and enables aggregation. A numeric, color-coded SAFE Score creates a common language across units and institutions, allowing EHS teams to aggregate

results, identify systemic weaknesses, and measure the impact of corrective actions. This is consistent with contemporary biosafety guidance that emphasizes protocol-driven risk assessment and repeatable controls as foundations for laboratory safety programs.[8,14]

Practical benefits and limitations.

SAFE assessments take minutes, require minimal training, and produce data suitable for dashboards and predictive trend analysis. **They are best used as a complement—not a replacement—for formal audits**: frequent SAFE checks maintain operational readiness while comprehensive audits evaluate systems, documentation, and compliance in depth.[11,12] Limitations include potential oversimplification of complex hazards and dependence on honest observation; these are mitigated by periodic calibration, cross-audits, and integration with incident reporting and formal audit cycles.

Implementation essentials:

To realize SAFE's value, organizations should adopt standardized scoring sheets, train assessors, define governance for escalation thresholds, and integrate scores into EHS dashboards. Over time, aggregated SAFE data can reveal seasonal patterns, staffing impacts, and the effectiveness of training—turning a simple triage tool into a predictive element of a mature safety program.

Quick comparison (key attributes)

Attribute	APGAR	SAFE
Purpose	Rapid newborn triage.	Rapid lab safety triage.
Domains	5 clinical signs.	4 safety domains.
Scoring	0–2 per item; total 0–10.	0–2 per domain; total 0–8.
Action	Immediate clinical interventions.	Immediate safety escalation and remediation.

Conclusion

The SAFE Score provides a rapid, structured, and standardized method for assessing laboratory safety readiness. Modeled after the APGAR score in pediatrics, it serves as a "safety vital sign" that guides immediate action without replacing comprehensive inspections. By evaluating four essential domains—Signage, Awareness, Facility, and Emergency Equipment—the SAFE Score enables organizations to identify gaps early, track trends over time, and cultivate a proactive safety culture. As laboratories face increasing complexity, staffing challenges, and regulatory

scrutiny, tools like the SAFE Score offer a practical and scalable approach to ensuring safe operations.

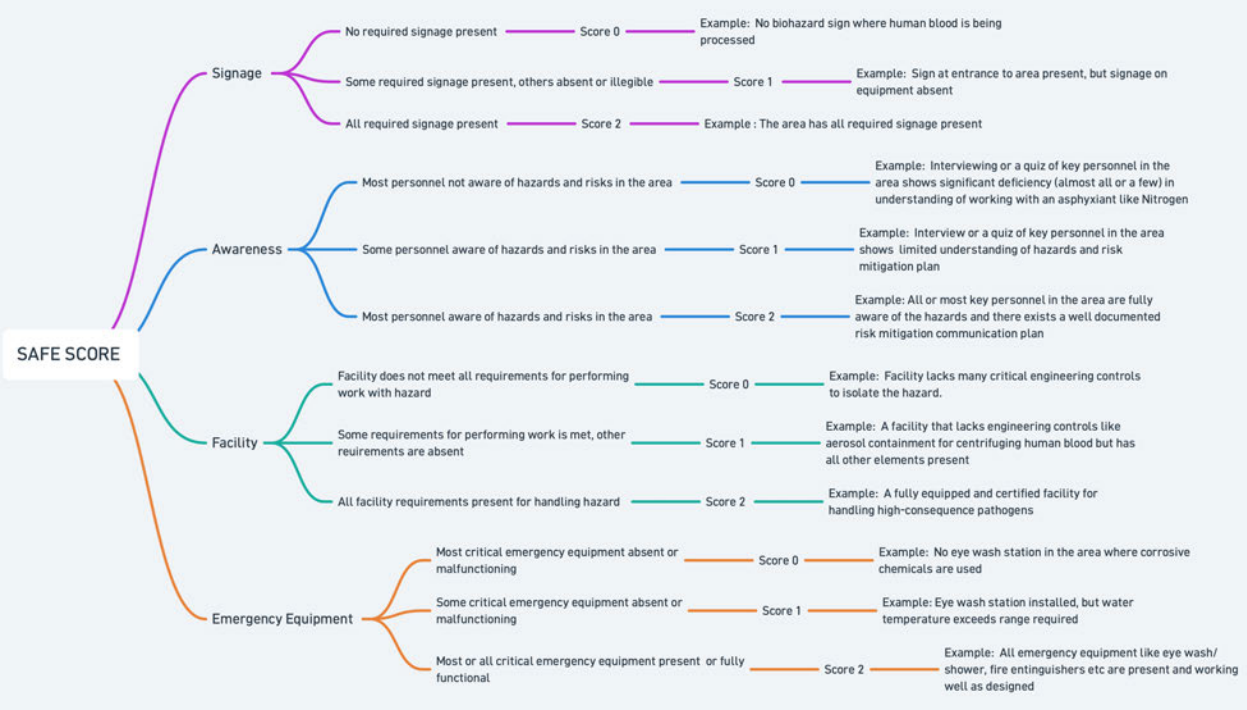

Figure 1. SAFE Score domain map. Schematic representation of the four SAFE Score domains: Signage, Awareness, Facility, and Emergency Equipment. Each domain is assessed using a 0–2 scale to generate a cumulative score ranging from 0 to 8. The framework is intended to provide a rapid, standardized indication of laboratory safety readiness by linking observable field conditions to a concise readiness metric.

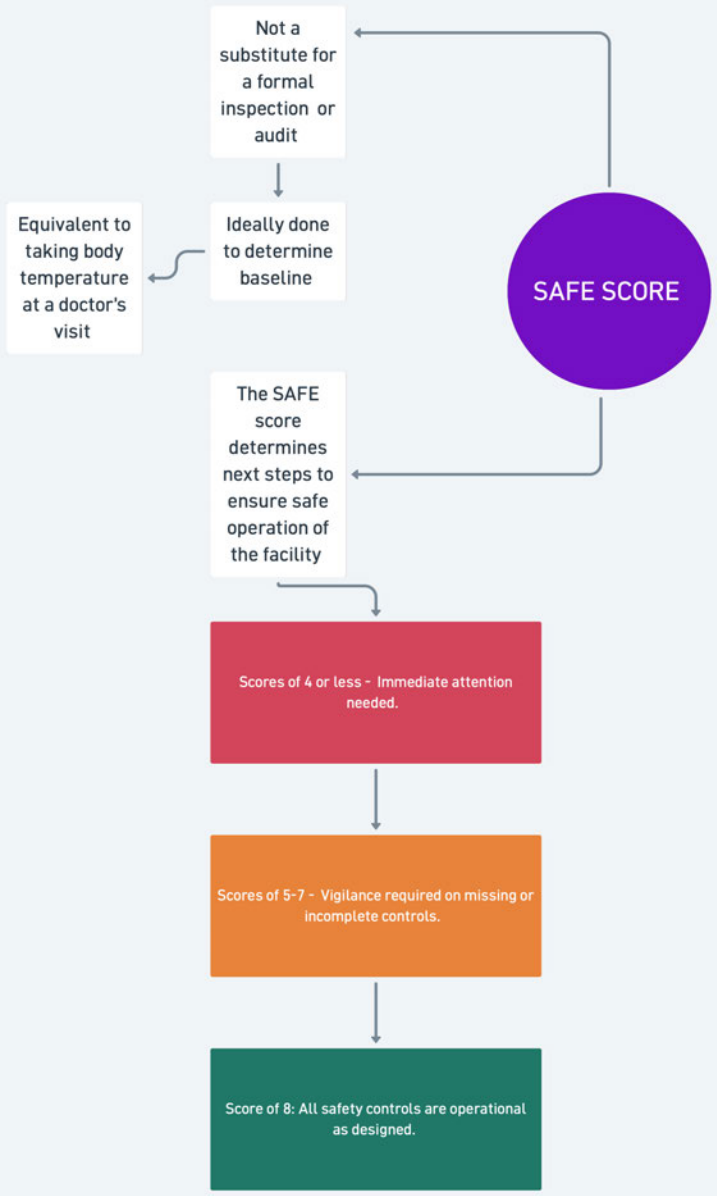

Figure 2. SAFE Score triage and response framework. Proposed interpretation of SAFE Score results as a decision-support tool for laboratory safety readiness. Higher scores indicate acceptable readiness with routine monitoring, intermediate scores indicate the need for targeted corrective action and reassessment, and lower scores indicate urgent escalation and immediate remediation. The framework links numeric scoring to predefined response thresholds to support consistent safety decision-making.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The major problem is that these definitions of biohazards are overly broad, and will in effect be like catching dolphins in the tuna nets. The first and third criteria are understandable and indeed would classify as biohazards. Applying this as done in #4 is then fine as well. However, #2 is a catchall - essentially any genetically modified model, cellular, viral, bacterial, or organism (i.e. animal) is considered a biohazard. This is not true, the vast majority of these conditions that are widely used in virtually all basic science laboratories in all fields do not pose any biohazard to humans in anyway. The mutations engineered are designed to alter the function of a protein or gene itself, they are then used to study molecular signaling, disease mechanisms, potential therapeutic avenues, etc.. None are transmissible and/or toxic to humans in anyway. Many of these are readily purchased by commercial entities, such as Jackson Labs for mouse models, or VectorBuilder and other companies for viruses that express mutated genes to form altered proteins. Many are made in our own laboratories using commercial kits and then used in cell culture or other experiments to study the molecular biology involved. If every one of these uses is now going to require the extensive documentation, surveillance, and oversight-approval from the academic institution and the PI investigator, this will amount to a huge time and administrative burden that will not result in any change in national or personal security. The administrative structures that are identified - both federal and local - should be applied to REAL RISKs - e.g. those entities that are in fact true biohazards. Labs that are involved with these types of materials already have procedures and administrative oversight in place and if these could benefit from added security by additional oversight - I am all for that. But for the 99.9999% of labs that routinely use genetically engineered models at molecular, cellular, or organ levels for their research, none of which pose biohazards to the investigators, the university where the studies are being done, or to the nation or world - there needs to be a much more rational filter. Most all activities involving modification of DNA or genes to alter cellular function used in biological studies do not impose any biohazard risks, and are simply current state of the art scientific approaches to doing the top level science. Imposing major complex administrative structures, demands, oversight, public postings, as proposed will only cripple the pursuit of cutting edge biological science in the U.S..

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am concerned that the language stating "research with primary cells that may be contaminated by adventitious agents" could be interpreted to include all research involving human blood and blood products. Because human blood and blood-derived materials are generally treated as potentially infectious, this wording may unintentionally capture a broad range of routine research activities.

I agree that appropriate review of the biosafety measures associated with the use of human blood and blood products is necessary, particularly because these materials may contain infectious agents of unknown status. However, I believe the policy should clarify that routine research involving human blood and blood products, when conducted under appropriate institutional biosafety practices, may be eligible for review and approval by an individual or subgroup of IBC members.

Adding this clarification would help distinguish routine work with human blood and blood products from research involving specific biological agents or other activities that warrant full IBC review. I believe this would reduce potential confusion and provide greater consistency in how the policy is interpreted and implemented.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft policy should clearly state whether the BMBL remains an advisory document recommending best practices for safe biomedical and clinical laboratory work, or whether it is intended to function as a regulatory document establishing mandatory standards.

I am particularly concerned that removal of the physical-containment appendix could be interpreted as allowing reduced or discretionary physical containment. The policy should explicitly clarify that the Physical Containment Levels outlined in the BMBL are required standards, not optional recommendations, where applicable. Removal of the appendix should not be interpreted as eliminating or reducing these requirements.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Microbiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The expansion of the biological toxins beyond Select Agents and Toxins is concerning. Arguably, most cell types will produce some type of toxin under some conditions, depending upon how the term "toxin" is defined. We also do not know the composition of the secretions of every cell type under every condition, and so it is difficult to even assess whether a molecule meeting the expanded definition of a "toxin" is being produced. Significantly more clarity on the definition of biological toxins and how to assess whether they are present is required.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The requirement to report exposure incidents within 24 hours is far too extreme. This will create an extreme burden on every IBC, and it is not clear that it would lead to any meaningful improvements in safety.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I don't see why human materials that may be contaminated with bloodborne pathogens need IBC oversight. The OSHA bloodborne pathogen standard lays out requirements for this work, so this is a huge increase in administrative burden with no tangible increase in safety from what was already in place.

Toxins behave more like chemicals than biological agents and the controls used for their safety reflect that. Safety Data Sheets are available for them. Their inclusion seems out-of-place. Many IBCs do not include chemical safety experts and chemical safety experts do not have the expertise to comment on other types of biohazards.

There was a reason that transgenic rodents were exempted previously. The draft policy explicitly says work with transgenic animals at (A)BSL-1 requires delegated member review and I do not see rodents exempted. We anticipate 100-200 investigators who never were required to submit previously to now have to write and submit an IBC protocol, which then have the be reviewed by our IBC analysts and delegated IBC members. What is the increase in safety? Animal escape is already under the IACUC purview.

I do appreciate inclusion of macaque materials that may be contaminated with Herpes B. By including them, you are closing a gap since that wasn't covered by an existing mechanism.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I appreciate the intent of increasing information disclosure, but the level of details needed for that extremely thorough template makes drafting the minutes a full FTE's worth of work. We timed it and it takes 40 more

minutes PER PROTOCOL to draft minutes that fit this template. This is an unfunded mandate. Currently, we redact almost nothing from our minutes, but if we need to put in some of these specifics, our legal counsel will redact a lot of it to protect active research.

Similar to the old NIH Guidelines, you could have made it mandatory that we release a full protocol by request if someone saw something in the minutes they wanted more information on. That would keep the information channels open, but not require this huge increase in administrative burden that may or may not have any real effect.

For incident reports, if someone is given a PI's name and the injured person's position and gender, it is often easy to narrow it down to 1 or 2 people with some internet sleuthing. I am concerned about the effect this will have on an injured person reporting to us. We try to make this process as non-punitive as possible, but if I were a researcher and made a silly mistake, I would be deterred from reporting if I knew my mistake would be published on a public website.

6. Other feedback relevant to this resource: I really need to know if it was your intention that "research with primary cells that may be contaminated with adventitious agents" include any human research protocol with a blood draw. Requiring those protocols go to meeting would add upwards of 50-80 protocols for committee review per month, when they are using precautions (Universal or Standard Precautions) reviewed by the IRB and dictated by the OSHA Bloodborne pathogen standard.

If transgenic mice need a protocol now for DMR, are we supposed to review every strain of transgenic mouse, or can approval be given for work with any transgenic mice that don't require ABSL-2? This is a huge group of people who never had to submit a protocol in the past and this makes a real-world difference in the administrative burden.

I understand the intent of a de novo submission, but our electronic protocol system has a tight connect for IRB studies and their associated IBC protocols. It will take a major development project to be able to close an IBC and reopen another for an IRB project that was approved and is ongoing. If it was just a de novo review without forcing a protocol to close and reopen, wouldn't you still get the intended fresh eyes on it? What does closing the protocol significantly add?

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Immunotherapy and AI Governance

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Checkpoint Governance for NIH Biosafety Oversight
Fred M. Cowan | President, Uppsala Inc. | 11 September 2026
Response to NOT-OD-26-112 — Draft NIH Biosafety Policy for Research Involving Biohazards

I recommend that NIH incorporate explicit, auditable decision checkpoints into its final biosafety policy and implementation guidance. The draft already provides tiered oversight, Institutional Biosafety Committee (IBC) review, and incident reporting. Checkpoint governance could help connect these provisions to verifiable conditions for proceeding, reconsidering, or stopping research. The practical question is whether a warning changes what happens next. AI innovation can provide a failsafe checkpoint system for biotechnology, AI safety and surety and many other applications.

My background includes U.S. Army Special Forces service (1969–1971) and approximately three decades of government biomedical research at the National Institutes of Health (NIH) and the U.S. Army Medical Research Institute of Chemical Defense (USAMRICD). My research in addition to checkpoints in immunotherapy and AI, spans chemical and biological countermeasures, including active/passive immunotherapy (API), disclosed in WO2001032207A1 as a proposed strategy for recruiting pre-existing immunity against selected targets, including infectious agents and toxins [11].

Lara Marks's history of immune-checkpoint inhibitors explicitly includes our NCI Fc-receptor studies and 1979 patent among the field's early developments [4,8]; checkpoint immunotherapy now constitutes a multibillion-dollar therapeutic field [6]. Our Multi-Threat Medical Countermeasures work articulated an injury-focused approach across chemical threats [5]. BARDA's chemical program now applies that central principle through broad-spectrum treatment and drug repurposing [7], while a 2024 HHS paper describes shared chemical and radiation injury mechanisms under "multi-utility" countermeasures [9]. These connections inform our broader checkpoint review [2].
Biological checkpoints illustrate how context-dependent activation and inhibition can preserve useful responses while limiting injury. Our pseudo-conscience proposal translates this regulatory principle into

a functional governance layer for detecting harmful trajectories, prompting restraint, and escalating unresolved concerns [12]. Applied to NIH oversight, AI could compare policy with evidence, flag inconsistent classifications or unsupported exceptions, track unmet approval conditions, and trigger accountable reconsideration. The PCT architecture supplies the proposed question-review, memory, provenance, and externalization controls [3]. This is an analogy and design rationale for evaluation; policy authority remains with accountable human institutions, and protective effectiveness must be demonstrated.

The coupling of AI capability with biological misuse makes biosecurity, including bioterrorism prevention, a direct checkpoint-governance application. Anthropic's September 2026 threat report describes five cases of AI use potentially supporting biological weapons development and attempts to evade safeguards; it does not assert that the researchers intended harm [10]. This supports evaluating the architecture proposed in PCT/US2026/036247 [3] as an additional layer governing passage from biological requests to released guidance or consequential action. Its protective value against biological misuse remains to be established.
The need for operational clarity is documented. In 2023, GAO found that an undefined review standard allowed potentially inconsistent interpretations of which proposals involving enhanced potential pandemic pathogens required departmental review [1]. A checkpoint should identify the decision, required evidence, responsible authority, and conditions that require escalation. I suggest five implementation priorities.

1. Review the question before authorizing the work. A Question Airlock should document the scientific objective, expected benefit, safer alternatives, assumptions, and material uncertainty. Review should consider relevant historical evidence and adverse findings, with unavailable information identified. Building on Section V, NIH should provide worked examples showing how agent characteristics, modifications, experimental context, and uncertainty determine oversight. Risk Group classification should inform this judgment without substituting for assessment of the proposed work.

2. Record a decision that controls passage. For each consequential transition, record GO, REVISE, HOLD, or WITHHOLD, with reasons and a named authorizing official. A compact Return Packet should preserve supporting evidence, provenance, unresolved concerns, alternatives, dissent, and approval conditions. GO should require verification that the applicable conditions are met. Implementation should support independent review and documented conflict recusals. A local checkpoint cannot authorize work prohibited by applicable requirements.

3. Keep approval responsive to changing evidence. Supplement scheduled reviews with explicit triggers for reassessment, including unexpected findings, containment failures, protocol changes affecting risk, and overdue information material to safety. Predetermined triggers should pause the affected activity and route the concern to the appropriate authority. Record who must respond, by when, and what evidence permits resumption. Preserve decision versions and the disposition of earlier warnings so that staff turnover or project continuation does not erase unresolved concerns.

4. Govern the transition from AI output to action. Guidance should address AI-assisted research as a coupled human, software, and laboratory workflow. A Question Airlock should review purpose and

cumulative context; the Return Packet should preserve evidence, warnings, and provenance. An Externalization Airlock should prevent release of high-risk guidance or execution of laboratory actions without independent, accountable authorization. Record relevant model and tool versions, evidence limitations, and the responsible reviewer. Enforce permissions outside the generating model, because a malicious or mistaken human operator may be part of the threat. Neither model confidence nor a human signature alone establishes that the required safety conditions have been satisfied.

5. Make learning and proportionality measurable. Use the proposed near-miss learning system to feed lessons back into checkpoint criteria, while preserving mandatory reporting and accountability. Provide common templates, training, and interoperable records usable by smaller institutions and voluntary participants. Pilot these measures against existing practice, including adversarial attempts to bypass controls, assessing time from warning to protective action, recurring failures, closure of safety conditions, and unnecessary delays to low-risk work. Interpret reporting rates in light of reporting culture; more reports alone do not establish worse safety.

Over my career, my work has benefited from millions of dollars in taxpayer-funded resources. That investment warrants scrutiny of both my claims and how institutions evaluate and preserve the resulting knowledge. Claims that exceed evidence require revision; potentially useful findings that were overlooked warrant examination. Checkpoint governance should make the evidence, unresolved questions, and reasons for advancing, deferring, or discontinuing work traceable.

NIH can specify these functions without requiring a particular vendor or patented implementation. The objective is earlier, accountable reconsideration while preserving useful research. The speed and cost of self-correction are themselves measures of how well science is working.

Role - Other: Biosafety Officer

Date Submitted: 9/14/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer biology, neurobiology, infectious and metabolic diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The overall scope of this new policy aligns well with our IBC scope. However, several key areas require further clarification, particularly regarding human clinical research protocols. I have attached a detailed document highlighting these specific items.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The tiered review seems appropriate.

3. Continued utility of Risk Groups: I agree with this approach. Starting with the Risk Group as the baseline makes complete sense. Once you assess the specific modifications to the agent and the nature of the planned activities, you can effectively assign and adopt the biosafety containment level and practical safeguards described in the BMBL.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): They seem proper to me.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Minutes - I support the effort to bring consistency to meeting minutes, but I have concerns regarding the required level of detail for some sections of the template (i.e. Project Overview and Risk Assessment). For example, for protocols involving multiple agents, documenting full agent description and mitigation plans for each of them will make the minutes overly dense and create a heavy administrative burden for the IBC staff. More importantly, including this depth of information risks exposing proprietary intellectual property. The level of details required in this template essentially reflects the entire protocol. Instead, these two sections should be replaced by a section to simply list the research items that apply to the policy, avoiding unnecessary detail while protecting Intellectual Property and streamlining workflow.

Incident Report – I believe the template itself works well, as it is very similar to the current version. While I appreciate the intent to promote public transparency, I am concerned that this policy may have

unintended consequences internally. Establishing and sustaining a non-punitive reporting culture remains a significant challenge, and considerable effort is continuously invested in encouraging staff to report incidents openly and without fear of repercussions. Knowing that these reports may be made public, even in redacted form, could discourage reporting, reduce internal transparency, and ultimately undermine the safety culture we are continually working to improve.

6. Other feedback relevant to this resource: Additional implementation resources would definitely promote consistent interpretation and implementation across institutions. This could include an expanded General Definitions section, examples within the Scope section, a FAQ document with representative scenarios, a decision tree for determining applicability, training materials or webinars to support institutions during the initial implementation phase and address common questions.

ADDITIONAL COMMENTS:

Scope - The four items listed in the Scope section are ambiguous with respect to clinical research involving human subjects. Additional language in further section adds to this confusion. For example, the “General Definitions” section states that "laboratory research" includes clinical settings. It is unclear whether what is listed in the Scope section is intended to include clinical research. In fact, the term “clinical research” is referenced only in Section IV-2. Also, because some institutions conduct veterinary clinical research, the document should specify whether the term “clinical research” refers solely to human clinical research. To address these inconsistencies, I recommend relocating information about human clinical research within the “Scope” section and clearly defining the scope requirements and applicability of the policy to clinical research activities.

Scope #1 - Specify the exact human population subject to this policy. Please clarify whether this applies strictly to healthy adult human subjects or extends to vulnerable populations, pediatric subjects, or specific clinical patient cohorts.

Scope #2 - For clarity, I recommend replacing the term “organisms” with “animals and other organisms” and providing representative examples to clearly define the intended scope.

General Definitions - This section should be moved to the beginning of the document rather than appearing midway through the text. Placing definitions upfront would improve readability and provide readers with the necessary context before encountering specialized terminology. Additionally, rather than defining only “Gene Drive”, the document should provide a definition for “Gene Drive Modified Organisms” (GDMOs). The acronym GDMO is used throughout the document without first presenting the full term or defining it when initially introduced.

Section IV-2
a) Specify the scope of primary cell sources and potential adventitious agents. It is not clear if this requirement applies strictly to human-derived primary cells or includes any other sources. Also unclear is whether adventitious agents are limited to pathogens with human tropism or extended to broader host ranges.

b) Clinical Protocols - As mentioned previously, to avoid confusion, I the applicability of human clinical protocols should be included in the Scope section instead.

● The reference to “products” in the second bullet is unclear and should be defined. Does this term include any biological product used in clinical (e.g. monoclonal antibodies, purified proteins) submitted to higher risk manipulation? If the intent is to refer only to the products described in the first bullet, the information should be rather incorporated into the first bullet to avoid confusion.
● Is that correct to assume that CAR-T cell clinical studies and mRNA vaccines no longer apply to this policy and don’t need IBC registration?
● What is the rationale for limiting the scope to RG2 WT agents? While biosafety programs are often focused on protecting the health professional, some RG1 organisms can pose significant health risks to immunocompromised patients.

Section IV - 4
a) Clarification is needed regarding NIH requirements for biological containment of transgenic animals. Does NIH require biological containment for any transgenic animals, or only when animals are exposed to microbiological agents, consistent with BMBL animal biosafety level definition?

b) What source of “well -characterized cells” apply to this section?

Description: I cannot see the document I've tried to attach being uploaded. Therefore, I've entered my additional comments in the #6 field

42. Mitchell Berger

I am responding: On behalf of myself

Name: Mitchell Berger

Name of Organization: None

Type of Organization: Not Applicable

Role: Other

Role - Other: Commenting in personal capacity

Date Submitted: 9/14/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Public health, behavioral health, emergency preparedness

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Commments on policy-potential changes to scope and definitions

1. Risk Management (Section V)
Add language stating that risk assessment should consider:
personnel competency and experience; supervision; compliance history;
incident/near-miss history; institutional safety performance.

This is especially important for work involving elevated consequences or uncertainty.

2. Definition of Acceptable Risk
Section V refers to “acceptable” risk without defining it. The policy should clarify:

acceptable vs. tolerable vs. unacceptable risk; how uncertainty affects the determination;
who has authority to determine residual risk is acceptable.

3. Gain-of-Function Research
The biosafety policy should explicitly align with NIH gain-of-function policies and address:
how NIH will coordinate review for research subject to both frameworks;
how NIH will prevent projects from avoiding higher-level oversight due to differing definitions;
how cross-agency jurisdiction works when another federal agency is involved.

The current language (“may proceed under the oversight of the other federal agency”) is too vague and risks gaps in oversight.

4. FDA Expanded Access IND — One Participant Exclusion
The policy excludes from NIH review any clinical product administered to one participant under an FDA

expanded access IND. Clarify:
why one participant is sufficient to exclude NIH review;
whether FDA will review biosafety aspects of such use.

5. Approval Duration
The policy's three-year approval limit may be too long for some studies and too short for others. Approval duration should be based on risk (e.g., BSL, agent characteristics, uncertainty), not a single fixed period.

6. Stop-Work Mechanism
Add an explicit stop-work provision allowing immediate suspension of research when:
conditions differ from those under which approval was granted, or an unacceptable risk is identified.
Clarify who can issue the order, how it is communicated, and how research may resume.

7. Definitions, Novel Agent
The definition of "novel agent" is too narrow. Recommend:

"Novel agent or organism: An agent or organism not existing in nature, deliberately designed, or newly arising through recombination or other processes, including those not intentionally engineered."

8. Definitions, Emerging Agent
The definition should reflect that agents may become higher-risk even if not newly identified. Recommend:
"Emerging agent or organism: An agent or organism that is newly identified, newly recognized as presenting significant human/animal/environmental risk, or whose epidemiological, pathogenic, ecological, or other characteristics have materially changed."

9. Definitions, Biological Agent
The current definition excludes several important categories. Recommend:
"Biological agent: Bacteria, viruses, fungi, parasites, prions, toxins, gene-drive modified organisms, insects or arthropods capable of transmitting disease, and other agents capable of causing human, animal, or environmental harm."

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Meeting minutes template
1. Investigator/Laboratory Compliance and Safety History
The current template captures basic principal investigator information (training, incidents, inspections, protocol details), but it does not ask the IBC to document whether the PI or laboratory has a relevant compliance or safety history. A dedicated field should be added:

Relevant Investigator/Laboratory Compliance and Safety History
(Including prior significant biosafety incidents; repeated or unresolved deficiencies; previous IBC required conditions;
completion and effectiveness of corrective actions; prior experience with the proposed hazard or containment level.
Including this information helps ensure the minutes reflect any history that may influence risk assessment or oversight.

2. Incident Documentation
The existing field ("Document any incidents…") should be expanded so the minutes capture more than a simple notation. Recommended additions include:
root cause and contributing factors; corrective and preventive actions (CAPA); responsible person/office; expected completion date;
verification of completion; assessment of effectiveness.

This level of detail supports the purpose of the minutes as both an institutional record and evidence that the IBC is meeting its oversight responsibilities.

3. Biosafety Level Assignment
The template asks for "Biosafety Level Assignment" and the "Basis for containment determination." It should also briefly explain why the committee selected a particular BSL (e.g., why BSL-2 was chosen instead of BSL-3, or why enhanced practices were considered adequate).

4. Risk Assessment — Uncertainties
The minutes should note key uncertainties discussed during review, such as:
limited data on the modified agent; uncertain host range; insufficient evidence of attenuation; uncertainty about environmental stability;
uncertainty about the effectiveness of proposed mitigations.

The minutes should also describe how the IBC addressed these uncertainties (e.g., conditions, monitoring requirements, restricted procedures).

5. IBC Vote — Clarification Field
In addition to "For/Against/Abstain," add: Significant Unresolved Concerns Raised During Review

This is useful when votes are close or heavily one-sided and helps clarify the nature of concerns that influenced the vote.

6. Conflicts of Interest
The template should request more detail, including: nature of the conflict (financial, employment, personal relationship);
whether the member recused themselves from the proceedings;
whether they abstained, voted, or participated in discussion.

7. Delegated Review
The “Readout of Any Projects Approved by Delegated Review” field should include:
a short description of the work; the approval decision; any conditions imposed; a brief explanation of why the protocol qualified for delegated review.

8. External Facilities/Services/Materials
Add a field documenting external facilities or services relevant to biosafety (e.g., specialized animal facilities, waste contractors, external labs). This is important when IBC conditions depend on external entities.

Incident reprot template comments:
1. Outcome of Incident
Add a field describing the outcome, such as: medical treatment; hospitalization; no treatment required; fatality;
long-term disability or morbidity; environmental or public-health impact.

If unknown, note: “Outcome currently unknown/pending follow-up.”

2. Lessons Learned
Add a field asking what lessons were learned, including whether the incident revealed gaps in training, procedures, equipment, facility design, supervision, risk assessment, or safety culture.

3. Cost/Economic Impact
Add a field for cost or economic impact.

4. Corrective Actions vs. Preventive Actions
Separate immediate corrective actions from longer-term preventive actions. Preventive actions may include supervision changes, SOP revisions, or engineering controls.

5. Effectiveness of Actions
Add fields for: implementation date; whether actions were effective; how effectiveness was evaluated; whether similar incidents recurred.

6. Recurrence/History
Add: “Has a similar incident, near-miss, deficiency, or SOP deviation occurred previously at this institution or laboratory?”

7. Known vs. Unknown Information
Because investigations may be ongoing, add fields for:

Known; Unknown/pending investigation; Not applicable.

The template can be updated later when the investigation is complete.

6. Other feedback relevant to this resource: N/A

43. Helen Scharfman

I am responding: On behalf of myself

Name: Helen Scharfman

Name of Organization:

Type of Organization: Not Applicable

Role: Other

Role - Other: Co-Chair of Institutional Biosafety Committee

Date Submitted: 9/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Neuroscience

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The term biohazards needs clarification regarding incident reporting.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Unclear what is meant.

3. Continued utility of Risk Groups: This is fine.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comment

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reports that are proposed carry an immense burden on the institution and investigators because of the detail proposed in the new reporting guidelines that need to be posted and in the minutes. The minutes have details that are redundant to what is already in the approved protocol. Repeating this in specific ways will be a huge burden on the institution and investigators.

6. Other feedback relevant to this resource: N/A

44. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Not Applicable

Role: Other

Role - Other: Biosafety Officer

Date Submitted: 9/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: '-I feel like there should be additional oversight for the clinical setting. Specifically, first in human genetic-based clinical products and genetic-based products with no previous clinical experience should be monitored by the IBC. We do not thoroughly understand the risks with these study agents and IBC guidance would be valuable. Additionally, the definition of higher risk manipulation is open to a wide range of interpretation. I would consider the use of sharps as a higher risk manipulation, but others might not.
-I did not see a mention of the size of the genetic alterations. Is it understood to be any size of stable genetic alteration, even very few base pairs?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: I agree with the continued use of RGs instead of BSL. Risk groups are more universally used and define the agent itself, while BSL is defining more of the precautions. Other countries, such as Canada, have studies that require IBC oversight, but they use Containment Levels, not BSLs. It also provides more levels of risk assessment and institutional policy.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I thought this section was good. I think the NIH guidelines are a good framework for all research, so that was well addressed.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It was unclear to me if institutions should be using that exact minutes templates or if it was just a guidance for suggested or required sections. The draft policy makes it seem like the exact template is required, but the minutes themselves feel less certain. Also, is there the ability to modify the minutes template to remove non-applicable sections or is the requirement to put “NA” for these sections?

6. Other feedback relevant to this resource: '-In a clinical setting, “respiratory protection” usually means the requirement to have a fit-testing program, so they can require N95s. Is this the requirement or was it meant to be a more general statement? Universal precautions does not generally include respiratory

protection, but instead focuses on protection against human bodily fluids, so mucus membrane protection is what is commonly used. This is achieved through PPE like face shields, eye protection, and face masks, instead of “respiratory protection.”
-It would be helpful to have more guidance on redacting. I know the document requests the sites provide their redaction policy, but it would be very helpful to have a template policy for them to start with. It is also unclear what items are allowed to be redacted.
-I have concerns about the public availability of the information regarding institutions that conduct “research in a BSL3/ABSL-3 or BSL4/ABSL-4 laboratory, research with GDMOs” on the institution’s website. Making this information publicly available on their website could potentially put them at greater risk for a biosecurity attack. It would be safer to have this information with the roster on the NIH, but not publicly available.

45. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 9/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Scope: The NIH Guidelines had some experiments that were low-risk, and therefore exempt. Since only wild type RG1 organisms and modified plants are exempt from this policy, do institutions need to have all work involving cloning in RG1 E. coli and yeast reviewed by the IBC (or a delegated review)? This needs to be clarified in the policy, to alleviate confusion with those that have been following the NIH Guidelines. A section with what is exempt should be included, even if it is only RG1 wild type biological agents and modified plants.

2. Section II
A. The definition of "disease", as pertains to this policy, is needed. For example: The wild-type biological agents and the toxins statements do not say "other than plants". For this reason, would poison ivy and/or urushiol be considered to cause a disease in humans and therefore be applicable to the policy? This type of information needs to be clarified, clearly explained, throughout the policy.

B. "other than plants" in the scope statements in all sections needs to be better defined. For example, scope statement 2 says that "Cells, viruses, or organisms, other then plants, that have been genetically modified" are applicable to the policy. Does this mean that modification of plant leaves, cells, tissues, as well as whole plants are not applicable to the policy; or, does "other than plants" only refer to whole plants?

3. Section IV-2
A. Statement 2 (research involving genetically modified cells, viruses, or organisms) does not state any risk groups, containment levels, or pathogenesis. Therefore, it appears that all genetically modified cells, viruses, or organisms (other than plants) need IBC review and approval. However, Section IV-3 then states that modified RG1 biological agents and certain viral vectors can be part of a delegated review. This is confusing.

4. Section IV-3

A. Statement 3 says that research with transgenic organisms at BSL-1/ABSL-1 can be reviewed as part of a delegated review. And so, if delegated review is not used they would need to be reviewed by the full committee. Does this mean that the purchase, breeding, and use of all transgenic mouse strains obtained from a vendor have to be reviewed by the IBC, even for experiments that don't involve administration of biological agents?

B. Statement 3 involves research with transgenic organisms. Transgenic means a transgene was inserted. Does this statement refer to those specific organisms, or does it refer to all modified organisms generated by any means (e.g., transgenes, site-directed mutagenesis, conditional expression, CRISPR, etc.)? Transgenic needs to be defined.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: 1. Risk Groups are a valuable tool for risk assessments, and for educating students, researchers, and the public about biological agents. Modifying an organism for research itself does not change the risk group. Trying to develop an attenuated organism does not mean the organism has lower risks. It still needs to be tested, which is why they are referred to as "candidates" during research. However, established and tested strains, FDA approved vaccines, or commercially available attenuated agents should be reviewed to determine if those specific strains can have a different risk group (as is already done and listed in the NIH Guidelines Appendix B).

2. 3rd and 4th generation replication deficient lentivirus viral vector systems (vectors themselves; nothing to do with the target genes being expressed) should be reviewed to have the risk group lowered to RG2. Depending on the genes being expressed, the containment levels would need to be assigned.

3. The published policy needs to include access to risk group designations. Without access to the information (the BMBL does not provide useful risk group information), implementing and being compliant with Section IV-1 is impossible.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: 1. Section III-A states that "No research subject to this Policy may be conducted until the institution conducting the research has provided a written Biosafety Assurance through the Authorized Organizational Representative (AOR) that has been approved by NIH, setting forth compliance with this Policy."
A. There is no information provided related to where and how the institutions submit the assurance.
B. There is no information describing when the assurance would need to be submitted in relation to the timeline of this Policy, and how long approval from NIH will take.
C. As this is a new policy, no institution has an approved biosafety assurance at this time. Does that mean that all NIH funded work applicable to this policy is expected to stop when the policy is published, or will there be an implementation time-frame in place, specific to the approved assurances, that takes into account the NIH's ability to review and approve all of the assurances that will be submitted when the policy is launched?

46. Daniel Kiss

I am responding: On behalf of myself

Name: Daniel Kiss

Name of Organization: not applicable

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 9/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): nucleic acid therapeutics

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: My major concern is that this new policy will enshrine an incorrect (and dangerous) definition of genetic modification as official NIH policy. I have quoted the problematic language below:

Genetic modification:
• The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:

• Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or

• Have the potential for one or more cycles of replication in a cell; or

• Can be transcribed or translated; or

• The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.

All prior definitions of genetic modification have centered on techniques and experiments that caused changes to the genomic DNA/RNA of the host cell, virus, or organism. However, as the text above shows, this proposed policy change ignores that decades-old scientific consensus. As the new language includes nucleic acids that “Can be transcribed or translated” this policy will incorrectly classify the vast majority of vaccine technologies as Genetic modification even though no vaccine platform alters the genome of the recipient.

For example, under this definition, all mRNA vaccines (whose sole function is to be translated into antigen protein that trains the immune system), all virally-vectored DNA vaccines (like the Oxford-AstraZeneca COVID-19 vaccine that has been given to ~2 billion people) which are transcribed into mRNA and then translated into the antigen, and selected live virus and virus-like particle vaccines will deemed genetic modifications as per official NIH policy. Simply put, including the “Can be transcribed or

translated" language as genetically modified is both scientifically wrong and irresponsible.

The dangers to public health and public trust by this inaccurate definition are enormous. It is easy to envision how anti-vaccine organizations can use this scientifically incorrect definition (which will become official NIH policy) to push regulators and policymakers to weaponize the policy and its enforcement mechanisms. Even if anti-vaxxers don't attack research institutions or universities, they will certainly use the new official NIH policy to falsely claim that vaccines are genetically modifying patients.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): My major concern is that this new policy will enshrine an incorrect (and dangerous) definition of genetic modification as official NIH policy. I have quoted the problematic language below:

Genetic modification:
• The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
• Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
• Have the potential for one or more cycles of replication in a cell; or
• Can be transcribed or translated; or
• The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.

All prior definitions of genetic modification have centered on techniques and experiments that caused changes to the genomic DNA/RNA of the host cell, virus, or organism. However, as the text above shows, this proposed policy change ignores that decades-old scientific consensus. As the new language includes nucleic acids that "Can be transcribed or translated" this policy will incorrectly classify the vast majority of vaccine technologies as Genetic modification even though no vaccine platform alters the genome of the recipient.

For example, under this definition, all mRNA vaccines (whose sole function is to be translated into antigen protein that trains the immune system), all virally-vectored DNA vaccines (like the Oxford-AstraZeneca COVID-19 vaccine that has been given to ~2 billion people) which are transcribed into mRNA and then translated into the antigen, and selected live virus and virus-like particle vaccines will deemed genetic modifications as per official NIH policy. Simply put, including the "Can be transcribed or translated" language as genetically modified is both scientifically wrong and irresponsible.

The dangers to public health and public trust by this inaccurate definition are enormous. It is easy to envision how anti-vaccine organizations can use this scientifically incorrect definition (which will become official NIH policy) to push regulators and policymakers to weaponize the policy and its enforcement mechanisms. Even if anti-vaxxers don't attack research institutions or universities, they will certainly use the new official NIH policy to falsely claim that vaccines are genetically modifying patients.

3. Continued utility of Risk Groups: My major concern is that this new policy will enshrine an incorrect (and dangerous) definition of genetic modification as official NIH policy. I have quoted the problematic language below:

Genetic modification:
• The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
• Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
• Have the potential for one or more cycles of replication in a cell; or
• Can be transcribed or translated; or
• The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.

All prior definitions of genetic modification have centered on techniques and experiments that caused changes to the genomic DNA/RNA of the host cell, virus, or organism. However, as the text above shows, this proposed policy change ignores that decades-old scientific consensus. As the new language includes nucleic acids that "Can be transcribed or translated" this policy will incorrectly classify the vast majority of vaccine technologies as Genetic modification even though no vaccine platform alters the genome of the recipient.

For example, under this definition, all mRNA vaccines (whose sole function is to be translated into antigen protein that trains the immune system), all virally-vectored DNA vaccines (like the Oxford-AstraZeneca COVID-19 vaccine that has been given to ~2 billion people) which are transcribed into mRNA and then translated into the antigen, and selected live virus and virus-like particle vaccines will deemed genetic modifications as per official NIH policy. Simply put, including the "Can be transcribed or translated" language as genetically modified is both scientifically wrong and irresponsible.

The dangers to public health and public trust by this inaccurate definition are enormous. It is easy to envision how anti-vaccine organizations can use this scientifically incorrect definition (which will become official NIH policy) to push regulators and policymakers to weaponize the policy and its enforcement mechanisms. Even if anti-vaxxers don't attack research institutions or universities, they will certainly use the new official NIH policy to falsely claim that vaccines are genetically modifying patients.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious disease animal models

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: "Any incidents involving exposures at BSL-2/ABSL-2 that require agent-specific treatment beyond basic first aid..."

This sector is overkill. Exposures to BLS-2/ABSL-2 is normally followed by prophylactic treatment. Although technically not first-aid, these prophylactics are normally given out of excess caution and are not really disease related. These could be handled by the IBC alone

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Date Submitted: 9/21/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): cancer

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: It will be helpful to explicitly state the NIH definition of "biohazard" and also state what it is not.
"Biohazard" was originally roughly "a biological organism or material that is a hazard". Not, for example, an x-ray machine or an ultraviolet lamp. Over the years, NIH Study Section members have conflated "biohazard" with "hazard", ie, "anything that is hazardous to a biological organism like a human". This results in a series of inappropriate requirements and red tape affecting non-biological hazards.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The risks associated with specific biohazards seem the same across all localities, ie, reasonably definable at the federal level. So would the mitigation and oversight methods. The challenge instead lies in which level (local vs federal) has the expertise, manpower, and motivation to oversee. Corporations have well documented conflicts of interest.

3. Continued utility of Risk Groups: I don't have the expertise to advise on this point.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I don't have the expertise to advise on this point.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I have nothing to suggest on this point.

6. Other feedback relevant to this resource: Just that please don't make such resources a series of webpages containing URLs to other webpages, often containing conflicting information.

Uploaded File: NIH_Biosafety_Draft_Public_Comment.pdf

Public Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Disclaimer

These comments are submitted in my individual capacity as a biosafety professional and reflect my personal views and professional experience. They do not necessarily represent the views, policies, or positions of my employer, affiliated institution, Institutional Biosafety Committee, or any other organization.

1. Scope of Biological Safety Officer Responsibilities

The draft policy appears to require the appointment of a Biological Safety Officer (BSO) only for institutions conducting Risk Group 3, Risk Group 4, or gene drive modified organism research. NIH should clarify whether duties traditionally associated with the BSO role, including laboratory inspections, compliance assessments, and other oversight activities, are intended to apply only to RG3/RG4 and gene drive research or to the institution's broader biohazards portfolio. Specifically, if an institution is not required to appoint a BSO because it does not conduct RG3/RG4 or gene drive research, it is unclear who is expected to perform functions such as laboratory inspections, biosafety compliance assessments, and other operational oversight activities that support IBC review and continuing oversight.

Without additional clarification, institutions may reach different interpretations regarding the applicability of BSO-related duties, resulting in inconsistent implementation across the research community.

2. Ability to Delegate BSO Responsibilities

The draft policy identifies responsibilities of the BSO but does not address whether those duties may be delegated to other appropriately qualified institutional personnel.

At many institutions, biosafety programs rely on teams of biosafety professionals, EHS personnel, subject matter experts, and laboratory compliance staff who collectively support inspections, training, risk assessments, incident investigations, and other programmatic functions under the direction of the BSO. Given the substantial expansion of policy scope and oversight obligations, it may not be practical or feasible for a single individual to personally perform all duties associated with the role.

Specifically, NIH should clarify whether:

- BSO responsibilities may be delegated to appropriately trained and qualified individuals operating under the authority of the BSO;
- Certain duties must be performed exclusively by the designated BSO; and
- Institutions may establish a biosafety program structure that distributes operational responsibilities among multiple personnel while retaining overall accountability within the designated BSO role.

Providing clear guidance on delegation would promote implementation consistency and better reflect how biosafety programs operate across diverse institutions.

3. Practical Implementation of Externally Administered IBCs

The draft policy contemplates externally administered IBCs while expanding IBC duties, including periodic review of approved research to ensure compliance.

Additional clarification would be helpful regarding how externally administered IBCs are expected to fulfill these ongoing compliance oversight responsibilities. Many of the responsibilities described in the draft policy, including periodic review of approved activities, assessment of institutional compliance, review of inspection findings, and evaluation of corrective actions, may require detailed knowledge of institutional facilities, personnel, training programs, and day-to-day operations.

Specifically, NIH should clarify:

- How externally administered IBCs are expected to conduct meaningful periodic reviews of approved research occurring at institutions where committee members may have limited visibility into local operations;
- Whether institutions utilizing external IBCs will be required to maintain local biosafety personnel or compliance programs to support these activities;
- How responsibilities will be divided between an external IBC and institutional officials responsible for implementing biosafety oversight programs; and
- What mechanisms NIH envisions to ensure consistency and accountability when ongoing compliance oversight responsibilities are shared between external committees and local institutional personnel.

Additional guidance in this area would help institutions determine whether external IBC models remain practical under the expanded oversight framework proposed in the draft policy.

4. Clarification of Public Posting and Incident Reporting Requirements

The draft policy expands incident reporting expectations and requires certain biosafety incidents to be reported to the IBC. However, it is unclear how the requirements for public disclosure and use of the NIH incident reporting template apply when an event is reportable to the IBC but does not meet the threshold for reporting to NIH.

Specifically, NIH should clarify:

- Whether incidents that require reporting only to the IBC must also be posted on the institution's publicly accessible website.
- Whether the standardized NIH incident reporting template is required for incidents that are reviewed solely by the IBC, or only for incidents that must be reported to NIH.
- Whether institutions may use their existing incident investigation and reporting mechanisms for IBC-only reportable events.

Additional clarification would promote consistency in institutional reporting practices and help ensure that public disclosure requirements are implemented as intended.

5. Clarification of Records Retention Requirements

The draft policy appears to link retention of biosafety oversight records to the retention period associated with the applicable funded research project. While NIH may intend to ensure that biosafety oversight records remain available throughout the lifecycle of supported research, additional clarification is needed regarding how institutions are expected to implement these requirements in practice.

Large research institutions frequently oversee numerous simultaneously active research projects involving multiple principal investigators, multiple funding sources, and varying grant periods. IBCs commonly review protocols, incidents, policy matters, and other agenda items that may affect multiple research projects during a single meeting. As a result, a single set of IBC meeting minutes may contain information relevant to numerous protocols and NIH awards with different project end dates and retention requirements.

Specifically, NIH should clarify:

- How institutions should determine the applicable retention period for meeting minutes and other records that pertain to multiple grants and investigators.
- Whether institutions are expected to associate individual portions of IBC records with specific awards.
- Whether a single retention period may be applied to institutional records that support multiple research projects.
- Why grant-specific retention requirements are necessary for institutional oversight records that may extend beyond any single funded project.

Several provisions of the draft policy significantly expand institutional oversight responsibilities while relying on institutional records that are frequently created and maintained at the committee or program level rather than at the grant level. NIH should consider providing additional implementation guidance to ensure that institutions can comply consistently and efficiently with the new requirements.

6. Clarification of NIH Determination of Minimum Biocontainment Levels

The draft policy states that IBCs are responsible for:

> "Petitioning NIH for determination of the minimum biocontainment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available in the BMBL. The IBC may not approve such research until authorized by NIH and any other applicable Federal, State, or local entities."

While this language clearly establishes a pathway for unresolved emerging, novel, or zoonotic agents, additional clarification is needed regarding biological agents that are not specifically addressed in the BMBL but are not determined by the IBC to be emerging, novel, or zoonotic agents.

Specifically, NIH should clarify:

- Whether NIH review is required whenever an agent is not listed in the BMBL, regardless of whether it is considered emerging, novel, or zoonotic.
- Whether IBCs may independently determine an appropriate containment level using available scientific literature, agent characteristics, risk assessment principles, and other authoritative guidance when the agent is not addressed in the BMBL.
- What criteria should be used to determine whether an agent is sufficiently "novel," "emerging," or "zoonotic" to require NIH consultation.
- Whether NIH intends to develop a formal process and timeline for responding to institution requests for containment determinations.
- Whether NIH containment determinations will continue to be issued on a protocol-specific basis for individual principal investigators and institutions, similar to the current process, or whether NIH intends to publicly post containment determinations that may be relied upon by other institutions conducting substantially similar research.
- If containment determinations will be made publicly available, whether institutions may rely on previously issued NIH determinations when conducting local risk assessments and protocol reviews without submitting a new request to NIH.
- Whether NIH intends to create a centralized repository, database, or other publicly accessible resource for containment-level determinations to promote national consistency in biosafety oversight.

Without additional clarification, institutions may arrive at differing interpretations of when NIH consultation is required. Some institutions may petition NIH for all biological agents not explicitly listed in the BMBL, while others may rely on institutional risk assessment processes. Similarly, it is unclear whether containment determinations will remain institution- and project-specific or whether NIH intends to establish publicly available precedent that can be used across the research community. Additional guidance in this area

would improve consistency, transparency, and efficiency while reducing duplicative review efforts for similar research activities.

7. Clarification Regarding Removal of Previously Exempt Activities

The draft policy appears to eliminate several exemptions that have historically existed under the NIH Guidelines, including certain activities involving well-characterized laboratory strains and routine activities involving established transgenic rodents.

Because these activities are commonplace at many research institutions and have historically been considered low risk, additional clarification regarding the rationale for removing these exemptions would be helpful.

Specifically, NIH should clarify:

- What biosafety concerns or oversight gaps prompted the removal of exemptions previously provided under the NIH Guidelines.
- Whether NIH has evaluated the anticipated increase in IBC workload resulting from review of activities that were previously exempt.
- Whether NIH intends to establish streamlined review mechanisms or administrative review pathways for activities that are widely regarded as low risk.
- Whether institutions retain discretion to implement abbreviated review processes for low-risk activities that no longer qualify for exemption under the proposed policy.
- How NIH expects institutions to allocate resources to accommodate the anticipated increase in protocol submissions and continuing oversight obligations.

Given the substantial expansion of the policy's scope, additional information regarding the rationale for removal of longstanding exemptions and the expected implementation approach would assist institutions in planning for compliance and resource allocation.

8. Clarification Regarding Delegated Review Authority

The draft policy permits review of certain low-risk activities through delegated review conducted by an individual or subgroup of IBC members. Additional clarification regarding the qualifications and authority of individuals performing delegated reviews would promote consistent implementation across institutions.

Specifically, NIH should clarify:

- Whether delegated review conducted by an individual must be performed by a current member of the IBC.
- If delegated review must be conducted by an IBC member, whether that individual must be a voting member of the committee.
- Whether alternate members may conduct delegated reviews.

- Whether subject matter experts, biosafety professionals, or other institutional personnel who are not appointed IBC members may perform delegated reviews when authorized by the institution.
- Whether delegated reviewers must report review outcomes to the convened IBC and, if so, what documentation requirements NIH expects institutions to maintain.
- Whether NIH intends delegated review to function similarly to designated member review processes used by Institutional Review Boards or whether a distinct process is envisioned for IBC oversight.

Additional guidance regarding delegated review authority would help institutions establish efficient review processes while ensuring that oversight remains consistent with NIH's expectations.

9. Implementation Timeline

The draft policy represents a substantial expansion of institutional biosafety oversight responsibilities and may require significant operational, administrative, and financial investments by regulated institutions.

Many of the proposed requirements will likely necessitate changes to institutional infrastructure, including modification of IBC procedures, development of new compliance and recordkeeping processes, expansion of biosafety program staffing, recruitment of additional subject matter expertise, implementation of new training programs, and updates to institutional policies and guidance documents.

As a result, the proposed six-month implementation period following publication of the final policy may not provide sufficient time for institutions to achieve full compliance, particularly for large research organizations with extensive research portfolios.

NIH should consider providing a minimum implementation period of twelve months following publication of the final policy. A longer implementation timeline would allow institutions to:

- Conduct gap assessments and develop implementation plans.
- Secure necessary budgetary and personnel resources.
- Recruit and train additional biosafety and compliance staff, where needed.
- Update institutional policies, procedures, and information systems.
- Modify IBC review processes and committee structures.
- Educate investigators and research personnel regarding new requirements.
- Establish compliance programs capable of meeting the expanded expectations of the policy.

Providing at least one year for implementation would improve consistency across institutions and support successful adoption of the policy while advancing NIH's biosafety objectives.

Conclusion

The draft policy frequently establishes new institutional responsibilities but does not always specify the operational processes by which those responsibilities should be implemented. Clarification regarding the scope of BSO duties, delegation of responsibilities, oversight by externally administered IBCs, incident reporting and public disclosure requirements, records retention expectations, NIH review of novel biological agents, removal of longstanding exemptions, and delegated review authority would improve consistency and facilitate implementation across the research community. In addition, the substantial expansion of institutional responsibilities warrants a longer implementation period than the six months currently proposed. Additional implementation guidance, decision trees, examples, clearly defined processes, and a minimum one-year implementation timeline would help institutions comply with the policy in a consistent and efficient manner while advancing NIH's goals of transparency, accountability, and biosafety.

50. Michael Eichner

I am responding: On behalf of myself

Name: Michael Eichner

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 9/22/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: support NIH's objective of modernizing and strengthening biosafety oversight and agree that biosafety requirements should evolve as scientific capabilities and risks evolve. However, I have significant concerns about the proposed expansion of the policy to encompass all genetically modified organisms, including routine genetically modified laboratory mice.

The proposed definition of research involving biohazards includes “cells, viruses, or organisms, other than plants, that have been genetically modified.” Under the proposed policy, research conducted with transgenic organisms at BSL-1/ABSL-1 would require review and approval by an individual or subgroup of IBC members before initiation.

This represents a substantial expansion of IBC oversight for genetically modified laboratory animals. Importantly, the presence of a genetic modification alone is not necessarily an appropriate proxy for biosafety risk.

Genetically modified mice encompass an extraordinarily broad range of research tools, including conventional transgenic animals, knockout and knock-in models, conditional alleles, Cre-driver lines, reporter strains, humanized models, and CRISPR-generated models. Many of these animals are well characterized and pose no meaningful biosafety risk beyond that associated with conventional laboratory mice.

I therefore recommend that NIH revise the scope of the policy so that the mere presence of a transgene or other genetic modification does not automatically trigger IBC registration and approval.

Instead, IBC oversight should be triggered when the genetic modification or proposed experimental use creates a credible biosafety, environmental, or biosecurity risk that warrants IBC expertise.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed policy appropriately recognizes that oversight should be proportional to risk. However, I am concerned that the

proposed treatment of genetically modified mice does not achieve that objective.

The draft places transgenic organisms maintained at BSL-1/ABSL-1 into a category requiring review and approval before initiation, albeit through delegated review by an individual or subgroup of IBC members.

While delegated review may reduce the burden associated with full-committee review, it does not eliminate the fundamental administrative problem. Registration, submission, review, approval, documentation, tracking, renewal, and amendment of thousands of routine mouse lines would still create a substantial institutional workload.

Moreover, the draft requires approval for a period of no more than three years, after which a new de novo registration and review would be required. Changes that could affect the original biosafety assessment would also require review and approval before the research proceeds.

For institutions with large biomedical research programs, this could translate into thousands of IBC registrations and subsequent administrative actions associated with genetically modified mouse research.

The resulting workload would not be trivial. It would require substantial effort from:

Principal investigators and laboratory personnel;
IBC coordinators and biosafety personnel;
IBC members and delegated reviewers;
Comparative medicine and veterinary personnel;
Animal facility personnel; and
Institutional administrative and compliance offices.

This workload would exist even when the underlying genetic modification presents no meaningful biosafety concern.

3. Continued utility of Risk Groups: A central principle of the proposed policy is that biosafety oversight should be calibrated to risk. I strongly support this principle and believe it should be applied more explicitly to routine genetically modified laboratory animals.

A transgene should not, by itself, be considered sufficient evidence of a biosafety risk requiring IBC approval.

For example, a mouse carrying a fluorescent reporter, tissue-specific Cre allele, conventional knockout, loss-of-function mutation, or well-characterized disease-associated knock-in is fundamentally different from an organism engineered to possess characteristics that could increase pathogenicity, transmissibility, host range, environmental persistence, or other meaningful biosafety risks.

The draft policy itself describes risk assessment as considering the characteristics of the biohazard, the manipulations being performed, and any genetic modifications. This risk-based approach should be used to distinguish routine genetically modified laboratory animals from organisms for which the genetic

modification itself creates a meaningful biosafety concern.

I recommend that NIH establish an explicit exemption or streamlined institutional determination for genetically modified laboratory mice when:

the animals are maintained at BSL-1/ABSL-1;
the genetic modification is well characterized;
the modification does not introduce a human or animal pathogen or toxin;
the modification does not create or substantially increase pathogenicity, transmissibility, environmental persistence, or host range;
there is no reasonable expectation of a significant environmental consequence from accidental release; and
the animals remain subject to applicable institutional animal-care, veterinary, and occupational-health oversight.

Such research could be documented through an institutional screening or self-determination process without requiring individual IBC registration and approval for each mouse line.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The potential administrative burden deserves particular attention.

Laboratory mice are one of the most widely used experimental organisms in biomedical research, and genetically modified mouse lines are routinely generated as part of basic and translational research. A single research program may generate multiple new lines in a year, while large biomedical research institutions may maintain thousands of genetically modified lines.

Requiring IBC registration of these animals would therefore create a volume of submissions that is fundamentally different from the type of research traditionally requiring intensive biosafety review.

Even if each individual submission required only a modest amount of staff and reviewer time, the aggregate burden could be substantial.

For example, if an institution generated or maintained several thousand qualifying mouse lines and each registration required only 30 minutes of combined investigator, administrative, and reviewer time, the resulting workload would already represent well over 1,000 hours of institutional effort. A three-year renewal cycle and amendments would create a continuing workload rather than a one-time implementation burden.

This raises an important question of resource allocation: Is the scientific value of requiring IBC review for every routine genetically modified mouse proportionate to the biosafety risk being addressed?

In my view, the resources of IBCs would be better directed toward research involving pathogens, toxins, novel organisms, gene-drive systems, altered host range, increased pathogenicity or transmissibility, and other activities for which specialized biosafety expertise is essential.

NIH itself identifies streamlining administrative burden as an objective of its proposed risk-based oversight framework. Routine genetically modified mouse research presents an important opportunity to achieve that objective.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Administrative Burden on IBCs

The potential administrative burden deserves particular attention.

Laboratory mice are one of the most widely used experimental organisms in biomedical research, and genetically modified mouse lines are routinely generated as part of basic and translational research. A single research program may generate multiple new lines in a year, while large biomedical research institutions may maintain thousands of genetically modified lines.

Requiring IBC registration of these animals would therefore create a volume of submissions that is fundamentally different from the type of research traditionally requiring intensive biosafety review.

Even if each individual submission required only a modest amount of staff and reviewer time, the aggregate burden could be substantial.

For example, if an institution generated or maintained several thousand qualifying mouse lines and each registration required only 30 minutes of combined investigator, administrative, and reviewer time, the resulting workload would already represent well over 1,000 hours of institutional effort. A three-year renewal cycle and amendments would create a continuing workload rather than a one-time implementation burden.

This raises an important question of resource allocation: Is the scientific value of requiring IBC review for every routine genetically modified mouse proportionate to the biosafety risk being addressed?

In my view, the resources of IBCs would be better directed toward research involving pathogens, toxins, novel organisms, gene-drive systems, altered host range, increased pathogenicity or transmissibility, and other activities for which specialized biosafety expertise is essential.

NIH itself identifies streamlining administrative burden as an objective of its proposed risk-based oversight framework. Routine genetically modified mouse research presents an important opportunity to achieve that objective.

Impact on Biomedical Research and Scientific Progress

The administrative burden would also extend beyond the IBC.

Modern biomedical research increasingly relies on rapid generation and evaluation of genetically modified mouse models. Investigators frequently create new models in response to experimental

findings, modify existing models to answer follow-up questions, or generate multiple related lines to establish causality.

This iterative process is particularly important for disease-discovery research.

For example, an investigator may identify a candidate disease-associated gene, generate a knockout or knock-in model, observe a phenotype, and then generate a tissue-specific or inducible version of the model to determine where and when the gene functions. Each subsequent model can be essential to interpreting the preceding experiment.

Adding a separate biosafety registration and approval process to each of these steps could introduce delays into an inherently iterative scientific process.

The cumulative effect could be significant: researchers may generate fewer models, delay experiments, or avoid exploratory lines of investigation because the administrative process required to initiate the work becomes disproportionate to the biosafety risk.

This is particularly concerning for research into diseases for which the underlying biological mechanisms remain poorly understood. Genetically modified mouse models are often essential to identifying disease mechanisms, validating therapeutic targets, and determining whether findings from cellular or computational systems translate into an intact organism.

Accordingly, the proposed requirement could unintentionally stymie scientific progress in disease discovery while providing little corresponding increase in biosafety protection for routine, well-characterized mouse models.

Relationship to Existing Animal Research Oversight

Genetically modified mouse research already occurs within a substantial framework of institutional oversight.

Investigators using these animals are subject to IACUC review and oversight, veterinary supervision, animal facility requirements, occupational-health programs, institutional policies, and established procedures for the generation, importation, transfer, housing, and use of genetically modified animals.

The draft policy appropriately recognizes the IBC, IRB, and IACUC as three foundational pillars of institutional oversight.

Rather than creating a duplicative approval process for routine genetically modified mice, NIH should consider how these existing oversight mechanisms can be leveraged to identify the relatively small subset of genetically modified animals that present meaningful biosafety concerns.

A risk-based screening mechanism could allow animal-care and biosafety professionals to identify circumstances requiring IBC review without requiring the IBC to formally register every genetically

modified mouse line.

NIH's effort to modernize biosafety oversight is important, and a stronger risk-based framework has the potential to improve biosafety while reducing unnecessary administrative requirements.

However, requiring IBC registration and approval of essentially every genetically modified mouse would create a large and continuing administrative burden for investigators, IBCs, biosafety programs, and animal research programs.

More importantly, the volume of routine mouse genetics that would enter the IBC system could overwhelm institutional biosafety resources and divert IBC attention away from research involving genuinely significant biosafety risks.

The proposed policy should therefore distinguish genetic modification from biosafety risk. A transgene should not automatically trigger IBC review.

NIH should establish a clear exemption or streamlined institutional determination process for conventional, well-characterized genetically modified laboratory mice maintained under BSL-1/ABSL-1 conditions. This would be more consistent with the stated objective of risk-calibrated oversight and administrative streamlining while preserving rigorous IBC review for genetically modified organisms that present meaningful biosafety, environmental, or biosecurity concerns.

The objective should not be to review every genetically modified organism. The objective should be to ensure that organisms presenting meaningful risk receive appropriate review.

That distinction is essential if NIH is to strengthen biosafety oversight without creating an administrative bottleneck that could impede the generation and use of the animal models that are fundamental to modern biomedical research.

51. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 9/22/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed scope is overly broad and would significantly expand NIH oversight beyond its traditional role. The policy would apply not only to NIH-funded research but also to non-NIH-funded research conducted at institutions that receive NIH funding. This expansion is not adequately justified and could have substantial unintended consequences for academic research institutions.

The scope also captures many low-risk and well-characterized experimental systems, including common genetically modified cells and organisms that have long histories of safe use. Inclusion of these activities may substantially increase administrative burden without providing measurable improvements in biosafety.

NIH should narrow the scope to focus on activities that present demonstrably elevated risk to laboratory personnel, public health, or the environment. Explicit exemptions should be created for established low-risk research platforms.

In addition, the public disclosure requirements associated with IBC review create concerns regarding protection of intellectual property, especially for early-stage discoveries that may ultimately become patentable inventions. Universities and investigators may be forced to file patents prematurely or alter research-development timelines to protect intellectual property.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): While risk-based oversight is an appropriate goal, the proposed oversight structure may not achieve meaningful risk stratification in practice because too many activities fall within the review framework.

A policy cannot be considered fully risk-based if low-risk and high-risk activities are both subjected to extensive documentation and review requirements. Many routine laboratory activities may become subject to additional administrative processes despite decades of safe use.

The proposed framework may also create substantial review bottlenecks at institutional IBCs. Large

research institutions could experience significant increases in protocol submissions, amendment requests, periodic reviews, and documentation requirements.

NIH should further reduce oversight requirements for low-risk activities and reserve the most intensive review structures for genuinely novel, uncertain, or high-consequence research.

The policy should also undergo pilot implementation at selected institutions before nationwide deployment to better understand resource and workload implications.

3. Continued utility of Risk Groups: Risk Groups and Biosafety Levels address different aspects of biosafety and should continue to be used as complementary tools.

Risk Groups provide critical information regarding the inherent biological characteristics of an agent, while Biosafety Levels reflect the appropriate containment requirements for specific experiments. Neither system should replace the other.

The draft appropriately recognizes that Risk Groups and Biosafety Levels are not equivalent. However, NIH should avoid creating requirements that could lead reviewers to rely excessively on rigid classifications rather than experiment-specific scientific risk assessment.

Particularly for modern technologies such as gene editing, synthetic biology, viral vectors, and attenuated constructs, professional scientific judgment remains essential. The final policy should preserve flexibility for investigators and IBCs to conduct case-specific assessments.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The enforcement provisions are concerning because they are linked to a policy that contains numerous areas requiring subjective interpretation.

The draft indicates that noncompliance may lead to additional award conditions, funding consequences, or other enforcement actions. Such provisions are appropriate for serious violations but may be excessive when applied to good-faith disagreements regarding risk classification, reporting thresholds, or oversight requirements.

NIH should distinguish clearly between:
• Serious biosafety violations that create genuine risk.
• Administrative or procedural errors.
• Good-faith differences in scientific judgment.

The incident-reporting requirements are also likely to encourage defensive overreporting. Institutions may report large numbers of low-risk events simply to avoid potential enforcement actions.

The policy should include:
• Clear reporting thresholds.
• Safe-harbor protections for voluntary reporting.
• Opportunities for corrective action before sanctions.

• Formal appeal mechanisms.
• Proportional enforcement standards.

Most importantly, public posting of institutional incident reports should not be required. Transparency can be achieved through NIH-generated national summaries that are de-identified and focused on lessons learned rather than institution-specific disclosures.

From an innovation perspective, the proposed requirement for public posting of IBC meeting minutes and incident reports presents substantial intellectual property concerns. Biosafety reviews frequently occur during the earliest stages of technology development, before patent applications have been filed. Even with redaction, mandatory public disclosure creates a risk of revealing commercially valuable scientific information, undermining patent protection, reducing industry engagement, and discouraging open discussion during biosafety review. NIH should replace institution-specific public posting requirements with de-identified national reporting of biosafety trends and incidents.

From a university PI perspective, the public-posting requirement is probably the aspect of this policy most likely to draw opposition from technology transfer offices, research universities, biotech companies, and academic inventors. The biosafety provisions themselves are unlikely to affect patents directly; the transparency and disclosure provisions could.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The NIH should require public reporting only of IBC decisions and biosafety determinations, not detailed meeting discussions. Detailed scientific deliberations should remain confidential institutional records to protect intellectual property, facilitate open discussion, and minimize unnecessary administrative burden.

1. Minutes should document decisions, not detailed scientific discussions

IBC minutes should record:

Attendance
Actions taken
Voting outcomes
Risk-assessment conclusions
Required containment levels

They should not require detailed descriptions of scientific methods, experimental constructs, unpublished technologies, or research strategies.

2. Intellectual property protection is a major concern

Many projects reviewed by IBCs involve early-stage discoveries that have not yet been patented.

Broad publication of meeting minutes could:

Undermine patent protection

Reveal competitive research directions
Complicate technology-transfer efforts
Discourage industry collaborations

NIH should explicitly allow omission of scientific details that are not essential for public understanding of biosafety decisions.

3. Public posting requirements create major administrative burden

The requirement to review, redact, approve, and post minutes may require substantial involvement from:

Biosafety offices
Institutional legal counsel
Compliance offices
Technology-transfer offices

This administrative burden is unlikely to improve biosafety.

4. Minutes should use standardized decision summaries

Rather than publishing extensive meeting notes, NIH should consider a standardized summary format:

Project category
Risk level
Containment level
Approval status
Special conditions

This would improve consistency and transparency while reducing disclosure concerns.

5. Public availability may inhibit open scientific discussion

Investigators and IBC members may be less willing to engage in candid discussion if comments could ultimately become publicly available.

Effective biosafety oversight relies on:

Open questioning
Honest discussion of uncertainties
Critical evaluation of proposed experiments

The meeting-minutes template should be structured to preserve this environment.

6. Other feedback relevant to this resource: The draft significantly underestimates the resources required for implementation.

Successful implementation will require:

• Additional biosafety personnel.
• Expanded IBC administrative support.
• Investigator training programs.
• Information technology infrastructure.
• Legal review of public disclosures.
• Processes for protection of confidential and proprietary information.

These requirements constitute a substantial unfunded mandate for research institutions.

The proposed six-month implementation period is unrealistic. Institutions will need considerably more time to:

• Revise policies and procedures.
• Train investigators and staff.
• Expand IBC membership and expertise.
• Review existing protocols.
• Develop systems for reporting and public disclosure.

NIH should provide:

• Standardized templates.
• Sample risk-assessment tools.
• Detailed implementation guidance.
• Decision trees for incident reporting.
• Frequently asked questions.
• Additional funding support.
• A phased implementation schedule extending beyond six months.

A revised draft should be released for an additional round of public comment before final implementation due to the magnitude of the proposed changes.

52. Newt Hilliard

I am responding: On behalf of myself

Name: Newt Hilliard

Name of Organization: Arkansas Tech University

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 9/22/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Microbiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: n/a

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Calibration of oversight to risk seems appropriate to the level of proposed research. Our current Institutional Biosafety Committee (IBC) is composed of both faculty, a community health care professional and a community engineering professional. All members have training and experience in working in environments with vary levels of risk. They are all aware of risk mitigation practices/procedures.

3. Continued utility of Risk Groups: Biosafety Levels have worked well for us since we do not currently have, nor do we plan to have, any research involving hazards above BSL2. This includes the growth of BSL2 level microorganisms for the purpose of isolating gDNA and cloning/expression of genes for non-toxic proteins in BSL1 level expression vectors. We might also perform limited growth of the BSL2 microorganisms for proteomics type analysis.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): n/a

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Since our IBC is relatively new, templates for both Incident reporting and Meeting Minutes are greatly appreciated.

6. Other feedback relevant to this resource: Again, our IBC is relatively new. We would appreciate any guidance available.

53. Lauren Walker

I am responding: On behalf of myself

Name: Lauren Walker

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am concerned that the proposed changes would significantly increase administrative burden and slow biomedical research. The expanded NIH oversight raises important questions about implementation: Who will be responsible for enforcing these requirements, and will additional personnel and funding be needed? What will the costs be to NIH and research institutions? While appropriate biosafety oversight is essential, the benefits of these additional requirements should be weighed against their potential to create delays, increase costs, and add unnecessary bureaucracy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

54. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Government Agency

Role: Government Official

Date Submitted: 9/24/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope should be expanded to include the recent USG Policy related to potential gain of function research. An agent that does not currently cause human disease could be used in a protocol that has the potential for gain of function. This could be revised to say "potential to cause human disease"

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A voting member recused from voting should not count towards quorum. The IBC should have the same regulations as all of the other committees when it comes to quorums and recusals.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Reporting to NIH within 24 hours seems unreasonable, particularly since NIH does not typically respond that quickly and is not available 24/7.
Posting minor incidents that the IBC handles on the public facing website seem excessive. the minutes will already be available so the information can be obtained if someone really wants it but it isn't as accessible for smaller incidents like minor mouse bite.

the IBC minutes meeting template is excessive regulatory burden that will cost every institution time, money, and overregulation. Requiring specific information be included seems more doable. With most facilities using electronic protocol management systems, many will not be able to shift to this specific format but adding details to the minutes is much easier. I see no reason for a specific required minutes template in this day of electronic software systems.

6. Other feedback relevant to this resource: This policy is very vague and while some leeway should be provided, it lacks a lot of detail that could prove difficult in the future. Examples:
-More details should be provided for the delegated member review-Is the Individual an IBC member?

What is a minor amendment?
-Risk assessments- prior to initiating research involving biohazards- Biohazards is not defined but does this mean only those reviewed by the IBC? Should the IBC review assessments from all biohazards, not just those that cause human disease?
-BSO- the duties are for the BSL3/4/GDMO work only? this should be changed to all facilities working with biological agents covered under this policy. Using biological agents that could cause human disease should come with a biosafety professional appointment. The entire BSO section is confusing. Does the last sentence for an institution without a BSO must designate someone with these responsibilities mean only the institutions required to have a BSO or those that aren't required to have a BSO still must assign these bulleted duties to someone else? This could be outlined much better to make this clear.
Training- while this remains the same from NIH Guidelines, a more specific timeframe or training outline should be provided. Requiring training every 3 years in coordination with the de novo approval would make sense.
-The IBC is given more responsibilities and options to make it more equal with the IACUC and IRB. however, there is no mechanism for protecting this authority. There should be ability for IBC to stop work, remove approval, etc. similar to the IACUC.
-Assurance- a lot more information will be required for this- how will NIH process all of these assurances initially? What should be included?
Implementation should be more than a year.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft policy will be a legacy of ineptitude by those who put it forth.
Delete the draft policy and start from the NIH Guidelines that have been developed for ~50 years.
Take into consideration the feedback NIH received by geographical area.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): RG2/BSL2 research is delegated review, whereas formerly exempt RG1/BSL1 research now requires registration and review... more paperwork for BSL1, fewer eyes on BSL2.
That is the exact opposite of tiering oversight and calibration to risk.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Empowering IBCs does not mean micromanaging by issuing and requiring a template for minutes.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The following relates to inadvertent gaps specifically within Section V-D. Requirements and Considerations for Risk Assessment of Manipulations of Biohazards.

AI-driven robotic labs have been discussed at length in the literature as a potential AI-enhanced biological risk as being capable of removing the human link to whistleblow on inappropriate research or protocols. I believe it would be prudent to include risk management principles within the section mentioned above or another appropriate section to preclude NIH awards to develop autonomous laboratory technology or use of autonomous laboratory technology when conducting NIH funded research without having constant direct human oversight. Said human oversight needs to be conducted by personnel who are appropriately trained to continually monitor the processes used by the AI agent(s) for risks while the research is conducted.

The following relates to the section: Section III-D. Responsibilities of the National Institutes of Health (NIH)

The NIH should work with all appropriate parties to develop a very simple emergency notification flowchart for each IBC to adopt and reference this within the draft incident reporting form. I know existing IBCs or similar institution research oversight bodies have reporting requirements but technology continues to develop faster than regulations. I believe having a standard call down emergency notification form for the initial minutes to an hour after awareness of an incident that could create public exposure is critical to provide any opportunity to contain further public risk. The notification flow chart should include all response organizations that have the personnel with knowledge, training, and readily available resources to respond immediately. This may include state and federal assistance. Further, NIH funding agreements should include language that prohibits institutions from delaying notification for the purpose of engaging in legal risk mitigation or reputation management activities prior to notification.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Federal for policy and NIH award stipulations. Institution level for implementing the policy.

3. Continued utility of Risk Groups: Risk groups are essential but evaluation of scope overlap or conflicting policies should occur with any NIH policy modifications.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Consider a public facing website that lists institutions that have signed a voluntary agreement to abide by NIH policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Related to section 1, the incident reporting template should be modified to state that completion of the form should occur after all immediate emergency notifications are made.

6. Other feedback relevant to this resource: I have nothing to add that is not stated above. Thank you for the opportunity to provide feedback.

58. Jeffrey M. Bell

I am responding: On behalf of myself

Name: Jeffrey M. Bell

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 9/28/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy should cover all work that can increase a pathogen's transmissibility or virulence in humans, not only recombinant nucleic acids. Gaps: privately funded work at NIH-funded institutions; agent transport; information and AI tools that lower the barrier to the same experiments. "Biohazard" that stops at current Risk Group lists will miss enhanced agents. A companion memo (attached) states the public-health case.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): High-consequence and genetically enhanced work needs federal review that the performing lab does not control. Local IBCs are necessary and not sufficient when the institution's funding depends on the project. Calibration to risk is right; "streamlining" must not mean the lab grades its own exam.

3. Continued utility of Risk Groups: Risk Group of the starting agent is a poor baseline once the agent is modified. Containment should follow the modified phenotype and BMBL BSL, with an explicit up-classification trigger when transmissibility or immune evasion is increased.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Policy without audit and a funding consequence is a guideline. NIH should be able to pause awards for unreported incidents and for work that matches a banned enhancement category. Voluntary compliance at non-NIH sites is not a substitute for a statutory floor.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Require a public, timely incident report: agent, enhancement status, BSL, whether NIH-funded, date, and whether IBC reviewed. Minutes should record dissent and the risk rationale, not only the vote.

6. Other feedback relevant to this resource: NIH should publish a one-page definition of prohibited enhancement, a decision tree for IBC up-classification, and a dual-use / AI-assisted experiment flag. Guidance that only restates BMBL will not close the gap.

Uploaded File: Zero-Pandemic.pdf

Description: Supplement to comments on Draft NIH Biosafety Policy: Zero Pandemic Initiative memo (definitions, independent oversight, enhancement research). Jeffrey M. Bell, individual, 28 Sept 2026.

Submitted as supplement to comments on Draft NIH Biosafety Policy, September 28, 2026. Jeffrey M. Bell, individual.

Full recommendation memo

1. Opening statement

High-containment laboratories are expanding rapidly around the world. Strong, consistent safety standards are essential to prevent laboratory accidents and reduce biosecurity risks.

That sentence names the documented problem (accidents and weak, uneven standards) and stays precise about the speculative piece (whether any given pandemic was caused by a laboratory). The policy is powerful because it holds up either way.

2. Keep two problems apart

The real argument — we need better standards, oversight, and facility design globally — works whether COVID was natural, lab-related, or something else. Do not hang the legal or diplomatic case on proving a lab origin. That is what makes the package defensible.

A public debate on why expert and public views of origins have diverged can still be hosted (conferences, the public database). It is a process track, not the legal trigger.

3. The goal: zero pandemics

Two categories, and only two:

1. Stopping creation — end dangerous gain-of-function research.

2. Stopping leaks — even if a pathogen were created, it cannot leave the lab.

Everything else in this sheet is how to get from the present “Wild West” (few standards, little public awareness of the danger of the technology) to that end state.

Pandemics are more than mortality rates. They wreck economies, overwhelm hospitals, spike mental-health harm, and disrupt education and daily life for years. Harm is often invisible in headlines — a fisherman’s livelihood, a family’s years of loss, millions of stories that never led the news. COVID caused an estimated 7+ million confirmed deaths globally, with excess-mortality estimates running higher, regardless of origin theory. We owe those who suffered through no fault of their own a multi-generational solution so this does not happen again.

If the United States had any role in COVID, that is an additional moral reason to lead. It is not the proof of the policy.

4. How to talk about this (sequence)

TBD

5. Pillar A — Stop creation

5.1 Immediate: existing executive policy

Under current White House policy:

• Agencies are banned from funding dangerous gain-of-function (DGoF) studies.

• Agencies do not decide whether an experiment is DGoF. The independent ITPRB (Independent Technical and Policy Review Board, or the successor independent review body designated in the policy) makes that classification.

Keep that structure. Do not let funding agencies grade their own homework.

5.2 Next: statute with real criminal liability

The executive order is the start, not the finish. Congress should pass long-term law that:

- Prohibits dangerous gain-of-function work, not merely defunds it.
- Makes surreptitious DGoF a prosecutable offense with real jail time.
- Closes the gap between “we will not pay for it” and “you may not do it in secret.”

The public message and the statute should match: this used to be tolerated; it is now a crime.

5.3 Why criminal law is part of safety, not only of politics

Published sequence data, commercial synthesis with legitimate research and pharmaceutical uses, and widely taught laboratory skills mean the barrier to misuse is getting lower, not higher. Policy cannot un-publish sequences or realistically shut off all synthesis. It can control facilities, personnel, funding, and covert work. Assuming there are no bad actors is naive. Jail for covert DGoF, access control, and tech-transfer limits are the intervention points that remain.

(This memo does not discuss methods of synthesis or misuse. It addresses only where law and institutions can intervene.)

6. Pillar B — Stop leaks: robotics-only laboratories

Human presence in high-risk workspaces is the long-run failure mode. Documented incident history is dominated by procedural error (see §9). The only multi-generational solution that matches that fact is:

Transition all future high-containment capacity to robotics-only labs.

If a dangerous agent exists, it still should not be able to leave through a torn suit, a missed step, or a tired technician.

Do not expand conventional labs now. Facilities built on today's human-staffed model will be obsolete once robotics takes over. Building more of them is waste.

A 2–4× construction-cost premium for safer, standardized, or robotic facilities is a rounding error against pandemic-scale downside. Societies already accept airport-level security to prevent thousands of deaths per incident. A lab-originated pandemic could kill millions. In expected-value terms, the premium is not the hard part of the argument.

7. Moratorium on traditional BSL-3/4 construction

Until robotic designs are standardized (on a 5–10 year planning horizon):

• Pause new traditional BSL-3/4 construction.

• Allow replacement only under the standardized interim design in §8, on a case-by-case basis, not as a new wave of conventional capacity.

Why this is a strong, defensible position:

1. Sunk cost. Nations spending hundreds of millions on facilities that robotics will obsolete is a real, countable waste.

2. Proliferation. A moratorium stops the growth of BSL-3/4 labs worldwide. That is risk reduction even if nothing else changes.

3. Rhetoric. "We should wait for the better standard" is pragmatic. "We should pause because of biosecurity fear" is easier to dismiss. Use the first framing.

This is also the diplomatic clock: every conventional lab poured in concrete now makes later coordination harder.

8. Interim period — before robotics is ready

Robotics is the destination. The country is in a vulnerable window before it arrives. Another pandemic in that window could set the work back for years. Assume the worst and prioritize getting the interim system in place now.

8.1 Interim facilities

1. Update current lab standards so they are more detailed and stricter. Keep them non-mandatory at first, while the new baseline is socialized and inspected.

2. Create one standardized interim lab design (not robotic yet). Use it to replace existing labs case by case.

Public security rises. Long-run cost falls versus each lab inventing its own standards.

8.2 Interim governance (human error and conflicts of interest)

1. NIH cash awards for whistleblowers who report dangerous practices. This is a named, non-negotiable item. It addresses the massive imbalance between insiders who see risk and a system that punishes them for speaking.

2. Revolving-door ban. Officials at HHS, CDC, and NIH may not be hired by pharmaceutical companies after leaving office. Make that illegal. Post-government employment otherwise shapes behavior while in office.

3. Public experiment database with three functions:

- report experiment types;
- rate dangerousness;
- host a debate section (pros and cons).

4. Facility access control. Personnel screening, training, and background checks before work with high-risk (including RG4) agents are a neglected gap. Standards vary widely around the world. Policy should specify who gets in, and with what. This is one of the few choke points that remains after sequences and synthesis tools are already in the world.

5. Mandatory, transparent incident investigation. About 9% of lab incident reports (1900–2025) list unknown or unclear causes. That usually reflects reporting gaps, not true mysteries. A facility that had an accident and covered it up or failed to investigate still appears as “unknown cause” — a blank, not “deliberately hidden.” Better reporting systems are better safety practices. Sunlight is the best disinfectant.

8.3 New lab-safety division

Stand up a lab safety division with a public-facing mandate: standards, incident transparency, database, whistleblower intake, and support to ITPRB classification.

Tooling preference recorded from source notes: standardize analytical support on Grok, on the claim that it is more truth-seeking than other systems. Treat that as an administration tooling choice to be justified in procurement, not as a scientific finding.

8.4 Who sits at the table

Faith-based groups already have a seat in this administration. Include one or more faith-based members in the gain-of-function and lab-safety debate. This is a legitimacy and values question as well as a technical one.

9. Evidence to put in front of the public

Verify and footnote before use. Figures below are compiled from the source notes, not independently audited in this draft.

1. How often lab incidents happen. Most people assume accidents are rare. Source notes cite 1,126+ documented incidents over 125 years, 81 fatalities in recent decades, and procedural errors in nearly 70% of incidents. That last number is the engineering case for robotics-only labs.

2. Global oversight gaps. Source notes cite 91.6% of countries with BSL-3 labs lacking dual-use oversight. Frame as a coordination problem, not a blame campaign. It is alarming and nonpartisan.

3. Who gets access. Ask a concrete question: What vetting does a technician undergo before working with RG4 pathogens? Standards vary widely. This is personal and easy to understand.

4. Named incidents stick. Use specific near-misses and breaches, not only totals. Source notes cite a Fort Detrick 2025 halt after protective-suit damage. Confirm the official record before using the example.

5. Unknown cause ≠ mystery. Source notes cite ~9% of cases (1900–2025) with unknown or unclear causes, typically investigation and transparency failures (see §8.2).

10. Diplomacy: U.S. leadership and the missing coordination mechanism

The United States should lead on:

- standardizing lab designs and robotics designs;
- creating jobs in that build-out;
- passing strong gain-of-function laws as an example the world can follow.

Countries have followed U.S. leadership on research infrastructure before — biosafety levels themselves are the precedent. That only works with early, clear signaling and coordination with allies before others lock into the current conventional-lab path. The window is narrowing as more labs are built.

Honor the President's 2028 commitment to an international conference on lab safety. In the near term, the President should hold conferences domestically and abroad as soon as possible:

raise awareness, reassure the public that the government is paying attention, and signal that future generations will not be left to another COVID — or worse.

The crux is not the technical argument. The technical case is solid. The hard problem is:

How do you get involuntary restrain on a lucrative, security relevant infrastructure decision when the coordination mechanism does not exist?

That may be harder than building the robotic labs. The conferences, the exportable standard, the moratorium, the statute, and ally coordination are that mechanism in draft form. They need to be stood up deliberately, not hoped for.

Technology transfer. High-risk laboratory and pathogen-related technology should not be shared with adversarial communist states. Treat this as an export-control and research-security rule aligned with the moratorium and the DGoF ban — not as a substitute for domestic lab reform.

11. Complementary integrity reforms (conflicts that shape the science)

These items sit beside lab safety because money, fame, and captured evidence streams are part of why dangerous work persisted.

1. Stop allowing pharmaceutical companies to produce and publish efficacy studies of their own products. Shift that function to NIH-funded studies, designed in coordination with FDA and industry.

2. Whistleblower cash awards apply here as well as in the lab — to correct a massive imbalance in who can afford to speak.

3. Major journals. Source notes allege that outlets such as Science were captured into a single permitted position and call for restoring independence and a range of views. In this memo that is recorded as a recommendation to restore pluralism, replication, and independence in high-impact publishing, not as an adjudicated finding of corruption. If the administration wishes to pursue it, it needs a separate evidence annex.

Political diagnosis recorded from source notes, not adopted here as a biosafety standard: that parts of government failed because unelected officials hold lasting power; that greed, vaccine-related money, and fame distort incentives. The operational responses already in this sheet are the revolving-door ban, independent ITPRB classification, NIH-funded (not sponsor-funded) efficacy work, whistleblower pay, and the public database.

12. Immediate action list

This week / this month

• Presidential remarks at home: the blunt GoF line; then incident frequency; then “we will not let this happen again.”

• Direct HHS and NIH to inventory DGoF-adjacent work against the existing funding ban and ITPRB process.

• Announce the construction moratorium on new traditional BSL-3/4 capacity pending robotic standardization.

• Announce NIH whistleblower cash awards (design the program in parallel; do not wait for perfect regulations to say the policy exists).

This year

• Transmit a statutory DGoF prohibition with jail for covert work.

• Draft stricter (initially non-mandatory) lab standards and the standardized interim lab design.

• Stand up the public experiment / dangerousness / debate database.

• Propose the HHS/CDC/NIH revolving-door statute.

• Begin ally consultations on a shared moratorium and robotics standard; restrict high-risk tech transfer.

• Charter the lab-safety division.

By 2028

- Hold the international lab-safety conference the President committed to.
- Have a U.S. robotics-only reference design far enough along that other countries can wait for it rather than pour conventional BSL-4 concrete.

13. Close

This is a remarkable moment: AI and automation can deliver multi-generational solutions, including standardized robotic laboratories. The irony is that the new threat arrives in the same window, before those laboratories exist.

59. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Commercial Entity (Biotech/Device/Pharmaceutical Company/Small Business)

Role: Institutional Review Oversight Committee Member

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious Disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Defining the scope as all organisms capable of causing human disease is overly broad. Some organisms widely used in modern biological research, such as E. coli, may cause human disease under certain conditions but should not automatically be included. The same principle applies to genetically modified cell lines. Many are harmless and widely used in research, despite having been genetically modified, and should not automatically fall within scope. Exemptions should be based on a risk assessment rather than a blanket definition.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Not clear and how is it going to be enforced. What is the repercussion for non-compliance.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: For private pharmaceutical settings, public disclosure can pose significant intellectual property risks that do not appear to have been adequately considered.

6. Other feedback relevant to this resource: This needs to be more detailed and better throught out.

60. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 9/28/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical, engineering, and agricultural research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: '-It is unclear who at a given academic institution should or must be selected as the Authorized Organizational Representative (AOR). Is this person serving as just a point of contact for the institution or would the person in this role have specific authority and responsibilities under the amended Guidelines? Please clarify who at an institution is expected or recommended to serve in this capacity. Would there be personal/professional consequences or implications for the person service as AOR in the event of an institutional lapse or failure to meet the guidelines?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: '-ABSOULTELY REMOVE the encouragement for an individual PI to report directly to the federal level for potential incidents. THIS WILL ABSOLUTELY CIRCUMVENT INSTITUTIONAL AUTHORITY AND SPECIFIC INSTITUTIONAL REPORTING PROCEDURES PUT FORWARD BY THE GUIDELINES. THIS RECOMMENDATION WILL PUT HUMAN AND ANIMAL LIVES AT RISK DUE TO UNDERREPORTING OR DELAYS IN INSTITUTIONAL AWARENESS ABOUT POTENTIAL INCIDENTS. In fact, IBCs would be completely unaware about potential incidents and this could result in significant delays in an institution's ability to respond appropriately in the interest to personnel and public safety!!!! Instead, recommend that PIs self report all potential incidents directly to the Institutional Biosafety Committee. This would help promote reporting and compliance by both the researchers and the institutions.

-Please keep the 3 year renewal plan rather than a de novo form after 3 years for previously approved protocols. Forcing PIs to submit de novo protocols for ongoing research that is well established and appropriate has the potential for significant confusion, protocol numbering/reporting errors (for ongoing work under multiple de novo protocol numbers over time). This would also create unnecessary paperwork and review work for both PIs and the Institutional Review panel members.

-Please specify/clarify institutional reporting of influenza in research personnel. Would this include institutional research personnel contracting influenza in a public sphere at the institution (i.e. interactions with people or animals at the institution outside the capacity of an influenza research focus)

or only those researchers specifically working with influenza as the focus of their research?

-What quantity is considered a "minor spill" of low risk agents? Depending on the type of research being conducted, one researchers "minor spill" could be a mL, for another a Liter!

-Add specific information regarding the level of registration/certification (Ex. "such as ABSA, etc.", training, and experience required to be a Biosafety Official or someone overseeing/supervising Biosafety Level 3 or 4 facilities in which NIH work is conducted. At present, anyone even those without biosafety background or experience would be able to run a secure facility, which leaves a wide door open for poor oversight, poor biosecurity, or poor responses following potential break in containment at such a facility.

-What risk group would/should new "biologics" requiring clinical trials and translational research fall under?

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Draft Meeting Minutes- It would actually be helpful to have the "New IBC Registrations and Amendments for Review (repeat for each registration)" as a separate addable page that each research group PI would be required to complete when submitting their protocol to the institutional review committee for approval rather than making the IBC Chair or equivalent collecting this information from multiple separate forms or PI attachments/emails before, during, or after the IBC meeting. This would streamline and standardize the protocol submission, approval, and reporting process for new IBC registrations and amendments across institutions. Make the individual PIs "generate the New IBC Registrations and Amendments for Review (repeat for each registration) " rather than the IBC Chair or institutional organizational leaders.

Conversely, this could be streamlined to just include written summaries of the proposed work rather than so many small detail boxes which are the bare minimum of what we go over as a committee prior to approving any protocol. Why would the federal government need that level of detail over ever approved protocol nationwide if the institutional oversight at that level is sufficient?! Our protocol forms are even more detailed than the reporting items requested but we are not allowed to attach those forms, but a summary of proposed research is considered not detailed enough by the fields on your proposed template form. Either make every research PI fill out their own detailed form using the same template for uniformity or allow IBCs to provide the simple paragraph summaries for those protocols for which they have reviewed and approved their own highly detailed protocol forms. Right now, this seems to redouble the effort required by making IBC fill out a detailed form using their own more detailed form without condensing any information whatsoever. We need LESS work to do on IBC not more.

6. Other feedback relevant to this resource: Primary clarification- Who would be the appropriate person at an institutional level to serve in the Authorized Organizational Representative (AOR) role and what would their specific responsibilities and authority be over research and reporting at that institution, or is this primarily a "point of contact role"?

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Human primary cells or established cell lines, without genetic modifications, are not in the scope of the proposed policy. Under current guidelines these are BSL-2.

Does the "other than plants" also imply "other than plan cells"? In that case plant cells expressing prions or toxins would not be covered by the proposed policy, though the toxins themselves wouls.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): no comment

3. Continued utility of Risk Groups: no comment

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): no comment

Uploaded File: Final-Comment-on-NIH-Policy.docx

After reviewing the policy several times, I am unable to understand how it can be considered logically coherent or feasibly implemented by the regulated community in its current form.

The statement that the intent of the new policy is to “expand the scope of the NIH Guidelines to all biohazards while removing red tape for low-risk research” is difficult to reconcile with the apparent expansion of oversight to include activities that were previously exempt. The policy states that its scope encompasses research involving biohazards, defined as “research involving known or potential risks to human health.” However, it subsequently discusses oversight of BSL-1 and ABSL-1 research, which, by definition, does not pose a risk to healthy humans. This is particularly challenging because the policy appears to eliminate exemptions for all BSL-1 and ABSL-1 containment work.

Requiring activities that were previously exempt to undergo, at minimum, delegated review—and requiring institutions to report to NIH if this zero-risk work proceeds before approval—provides no apparent benefit to human health or safety. Instead, it imposes a substantial administrative burden on covered entities and researchers and adds precisely the type of red tape the policy claims to remove. If NIH does not intend to cover activities that were previously exempt, that should be stated clearly. If the policy’s true objective is to protect human health and safety while minimizing unnecessary administrative requirements, then all work conducted at BSL-1 or ABSL-1 containment should be exempt from IBC reporting and review.

Similarly, the overly broad definition of “toxin,” as well as the addition of chemically or radiologically induced mutations as covered activities, appears unlikely to provide a meaningful benefit to human health while creating additional administrative burdens. Why not establish quantitative criteria for defining toxins, such as an LD50 threshold? Clear criteria would allow institutions to provide enhanced oversight for work that may pose a meaningful risk to human health while preventing the misuse of resources on materials of negligible concern. As the policy recognizes for proteins, toxins are more appropriately considered chemicals and should therefore be regulated through existing chemical-safety requirements. Likewise, coverage of chemical and radiological methods used to induce mutations appears redundant with existing regulatory oversight and is therefore unnecessary. The resulting biosafety considerations are also very low risk and should not warrant additional oversight, much like the breeding of transgenic mice.

At our institution, I estimate that adding protocol reviews for currently exempt activities alone would increase the number of required protocol reviews approximately sixfold. Implementing this change within six months would not be feasible without adding staff. In addition, because protocols would require review every three years, institutions could face recurring surges in workload as large groups of protocols become due for renewal simultaneously. If NIH truly intends to impose this additional burden on covered entities, I ask that the six-month implementation period be reconsidered and extended—particularly for activities that present little or no risk.

I am also concerned that the requirement to publicly post incident reports and submit them to NIH could create health and safety risks by discouraging researchers from reporting incidents to their institutions, particularly when the activities involve no or minimal risk. This approach could transform biosafety professionals into enforcement personnel rather than allowing them to cultivate the trusting, collaborative relationships with researchers that are essential to identifying and addressing problems before they result in exposures or releases. The potentially punitive nature of the requirement is reinforced by the request to include grant information on the reporting template. Is this information truly necessary, especially when institutions may be expected to report relatively minor events?

In short, it would be welcome if NIH were genuinely interested in reducing administrative burdens associated with low-risk research. In its current form, however, this policy appears to exacerbate those burdens. I urge NIH to reconsider the scope of the policy so that institutions can direct their resources toward activities that present meaningful risks and require enhanced oversight.

This is not gold-standard biosafety supporting gold-standard science; it is unnecessary bureaucracy and inefficiency.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: six month implementation timeline is unrealistic. The policy becomes effective six months after publication of the final version and appears to require approved Biosafety Assurance before research may continue. Even at institutions with robust biological safety and security programs, most will need to update or create redaction procedures; modify protocol management systems (whether they be in house or purchased from a vendor); develop new training materials - more so figure out what the PIs will be presenting since it is now their responsibility as outlined in this draft; expand protocol inventories; train investigators, IBC members, and biosafety staff; establish new incident reporting policies

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. "Clinical research cannot be initiated until IBC, and all other applicable institutional and regulatory authorization(s) and approvals have been obtained."

This should be clarified, such as "clinical research, as pertains to the scope of this policy,..."

As written, this could be interpreted as ALL clinical research requires IBC approval, even a research project that is just a retrospective chart review.

2. "Research with primary cells that may be contaminated by adventitious agents"

As written, this could be interpreted as ALL clinical samples that contain cells (such as a blood draw) require IBC approval, as even donor screening cannot rule out all adventitious agents and the guidance as written states "MAY be contaminated". I think this language needs refinement and could cause unforeseen regulatory problems/considerations for institutions to have it written this broadly in scope.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: I think it is at least a good starting point to have Risk Groups. It makes sense to me to have a good baseline be RG level = BSL and then you upgrade or downgrade based on risk assessment, but it gives institutions a starting point.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Helpful, but some of the guidelines overlap with other institutions, such as the SRSS at the VA is already reviewing "Research with primary cells that may be contaminated by adventitious agents".

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It would be better, in my opinion, to have a draft meeting minutes template that is required to use OR an institution may use

their own template as long as their template contains, at minimum, the same details and information required in the template.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Modernization should not be an unfunded mandate.
This draft substantially expands biosafety oversight responsibilities, increasing transparency, establishing new reporting obligations and requires expanded institutional infrastructure. The policy does not identify corresponding funding mechanisms to support these mandated activities. Depending on the institute, this proposal may required new and or additional biosafety personnel, expanded administrative support, new and or improved information technology infrastructure, public reporting systems, training development, increased protocol management capacity, enhanced institutional oversight activities. This could bring about substantial new and or additional costs to smaller institutions, teaching focused universities, hospitals and emerging and re-emerging research organizations

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support efforts to modernize biosafety oversight, but I oppose this draft policy as written. The proposed NIH Biosafety Policy for Research Involving Biohazards is too broad and too ambitious, and it is much more likely to overburden the research system and slow the pace and productivity of NIH-funded science than to meaningfully reduce harm.

My biggest concern is the extremely broad definition of "genetic modification," which appears to capture a wide range of common methods and fields that are essential for the mechanistic rigor expected in NIH-funded research. If implemented as written, this policy would sweep too much routine and low-risk work into formal oversight, overwhelm IBCs and institutional systems, greatly increase administrative costs, and significantly delay the initiation of new studies.

I am also concerned that the extensive public posting requirements for minutes, incident reports, and other materials would place further strain on already underfunded and administratively overloaded research institutions. At a time when investigators and institutions are already burdened by extensive compliance and documentation requirements, this proposal would add substantial paperwork and delays without clear evidence of proportional benefit.

NIH should significantly narrow the scope of this policy, better define truly high-risk activities, and avoid creating an oversight framework that impedes research more than it improves safety.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support the general principle of tiered oversight and agree that some federal oversight is appropriate, especially for NIH-funded research and for higher-risk or novel work. However, the draft policy as written appears insufficiently calibrated to risk and is likely to pull too much routine, low-risk research into expanded oversight. This risks overwhelming both federal and institutional review systems, slowing the initiation of studies, and diverting attention away from research that truly warrants heightened scrutiny. Federal oversight should remain focused on clearly high-risk, novel, or uncertain activities, while local oversight should be streamlined for routine and well-understood work.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting and meeting minute requirements appear likely to create substantial additional administrative burden for investigators, IBCs, and institutions. In particular, the public posting expectations for minutes, incident reports, and related materials may be difficult to manage in practice and could further strain already under-resourced research and compliance systems. These requirements risk increasing paperwork and delay without clear evidence of proportional safety benefit. NIH should simplify these templates and limit required public posting to only what is truly necessary for transparency and accountability.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: '-Are recombinant plants going to be regulated by the USDA or another group? I have strong concerns about potential recombinant plants spreading into wild type, which could be detrimental to our farms and food supply.
-It would be very helpful to include the BSO section that this individual should be a Subject Matter Expert in this area.
-It would be very helpful to define "adventitious agents."
-Will all human samples have to be regulated by IBCs? Human samples are RG2/BSL2 automatically, including work with non-fixed human tissues. Could this be an exemption?
-Will there be any exemptions for transgenic animal research? There are many animal strains that are considered exempt now and pose very little risk. The administrative burden of the IBC reviewing all these studies would be very large.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: '-Are aggregate publicly available incident reports for non-NIH reportable incidents acceptable? This would help prevent HIPAA concerns and provide a better explanation of what occurred at the institution.
-It feels like these guidelines are leaning very heavily on the BMBL. My understanding was that the BMBL was guidelines, not rules, so this is a difficult concept to change my mind about. I also feel like there are gaps in the BMBL that were previously addressed in the NIH guidelines, but will no longer be addressed.
-Will all teaching labs be required to have IBC approval, even if they are only doing basic BSL1 recombinant work in their teaching labs? The administrative burden of maintaining IBC approval for this

type of work is very large, although the risks are incredibly small.
-BSL1 biological agents in clinical settings should also be under IBC oversight, especially with the use of needles and aerosols. The risk is greater for these procedures and they clinician is at greater risk.
-It is unclear to me if the delegated/sub-group review can only occur after full committee review as amendments or in general. It is worded in a confusing way.
-Respiratory protection is not a universal clinical precaution. It would be better to say, ..."universal precautions, such as glove and mucus membrane protection."

6. Other feedback relevant to this resource: "Genetic modification" is expansive enough to capture conventional selection and non-biological hazard programs
The definition includes stable alterations produced through passaging, reassortment, chemical means, or radiological means.
This creates several internal tensions:
• The policy is framed as biosafety oversight of biohazards, but the definition may capture organisms altered through chemical mutagenesis or irradiation.
• Genetically modified RG1 agents require delegated review, even if the modification does not plausibly increase risk.
• An organism selected through passage could be regulated as genetically modified even without recombinant or synthetic nucleic acid manipulation.
• The definition may turn attenuation by passage into "genetic modification," while the wild-type definition excludes organisms with deliberately introduced modifications.

This will take significant resources to identify some of the lower-risk research involving this new definition (e.g., passaging RG1 organisms), as well as harmonizing with chemical and radiation oversight - another significant burden without a benefit of mitigating risk. These types of modifications will be easily

identified and reviewed at RG2 and higher, as "WT" organisms with that level of risk are also covered under the policy draft.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): all

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: the proposed National Biosafety Data and Safety Analysis Center provisions in the draft policy is unclear - whether the goal is to streamline existing reporting pathways or create an additional reporting requirement given the potential duplication with FSAP, CDC, USDA, OSHA, and other federal partners. Improving transparency and learning from biosafety incidents, especially LAIs, is central to the biosafety profession.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: NIH determinations are described as both project-specific and generally published precedents
IBC petitions must contain experiment-specific details, including modifications, biological systems, manipulations, reagents, animal work, local containment, and the institution's risk assessment. NIH then publishes approved determinations for lower-containment research.
Unresolved issue: It is unclear whether a published NIH determination:
• applies nationally to equivalent work;
• is limited to the requesting institution;
• is limited to the named PI, facility, construct, or procedure; or
• may be relied upon by a different IBC without another NIH petition.
This directly affects whether the approval system becomes a reusable national resource or a series of duplicative case-by-case requests.

6. Other feedback relevant to this resource: “Well-characterized cell lines” are assigned delegated review without a clear scope basis
The scope applies to cells or organisms containing covered agents or modifications, but Section IV-3 separately lists research with well-characterized cell lines.
Unclear result: A non-recombinant, well-characterized human cell line may be included under IV-3 even when it is not known to contain a pathogen and does not independently satisfy the scope definition.
Conversely, Section IV-2 requires full IBC review of primary cells that “may” contain adventitious agents.
The policy needs explicit criteria distinguishing exempt cell culture, delegated review, and full review.
why duplicate what the OSHA Bloodborne Pathogens Standard currently covers

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The Draft Does Not Clearly Demonstrate a Reduction in Administrative Burden for Low-Risk Research
One of the primary objectives stated throughout the modernization effort was to expand oversight of higher-risk activities while simultaneously reducing unnecessary burden for low-risk research. The draft successfully broadens oversight to include many biological hazards beyond recombinant and synthetic nucleic acid technologies; however, it is less clear how the proposal reduces burden for lower-risk activities.
Several provisions may actually increase review and documentation requirements for activities historically considered low risk, including:
• Certain RG1 genetically modified organisms (e.g., commercially available ABSL-1 mice/rats);
• Transgenic organisms maintained at ABSL-1 or BSL-1;
• Certain plasmids and viral vectors;
• Well-characterized cell lines;
• Lower-risk incident reporting; and
• Expanded delegated-review documentation requirements.
Additionally, the proposal creates new documentation, transparency, reporting, and public-record obligations that may increase administrative workload at all levels of oversight. NIH should more clearly demonstrate how the proposed framework achieves its stated goal of reducing administrative burden for

low-risk activities and should consider additional exemptions, registrations, or administrative-review pathways where biosafety risk is well understood and minimal.

6. Other feedback relevant to this resource: Facility responsibility is assigned to the PI even when facilities are institutionally managed
The PI must ensure the “integrity, maintenance, and correct functioning” of facilities, physical containment equipment, and PPE. The institution and BSO also carry programmatic and inspection responsibilities.
Conflict: A PI may control use of equipment and reporting of defects but not building ventilation, certification contracts, capital repairs, emergency power, or institutional maintenance systems. The policy should divide responsibility among the institution, facilities owner, BSO, PI, and equipment user.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: BSOs Remain Underdeveloped Despite Expanded Reliance on Risk Assessment
The draft repeatedly emphasizes risk assessment as the cornerstone of oversight, yet devotes relatively limited attention to the qualifications, authority, and role of BSOs.
The policy assigns BSOs responsibilities such as inspections, incident response, reporting concerns, and technical consultation. However, it does not establish:
• Minimum qualifications;
• Competency requirements;
• Continuing education expectations;
• Certification standards;
• Staffing expectations;
• Reporting independence;
• Stop-work authority;
• Formal authority to require corrective actions; or
• Required participation in protocol approvals or incident determinations.
Further, institutions without a designated BSO may simply assign these responsibilities to another institutional official, raising questions regarding qualifications, consistency, and independence.
If NIH intends risk assessment to become the central principle of biosafety oversight, then BSOs should

be strengthened commensurately through national competency expectations, training programs, and clearly defined authority.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: IBCs Were Given More Responsibilities, Not More Authority
One of the stated goals of modernization was to strengthen local biosafety oversight. However, the draft primarily increases IBC responsibilities without substantially expanding IBC authority.
The policy places significant new obligations on IBCs, including expanded protocol review, incident review, public posting of meeting minutes and incident reports, review of lower-risk incidents, maintenance of public records, and coordination of NIH approval requests. At the same time, the policy does not:
• Provide explicit enforcement authority;
• Establish mechanisms for suspending unsafe research;
• Create accreditation or certification standards;
• Provide enhanced institutional protections or independence;
• Develop standardized national training resources; or
• Provide additional funding to support these expanded responsibilities.
As written, IBCs appear to assume substantially greater workload without receiving corresponding increases in authority, resources, or institutional standing.

6. Other feedback relevant to this resource: “Laboratory research” includes clinical settings, but clinical research is treated as structurally different
The definition says laboratory research includes clinical settings within BSL/ABSL 1–4 containment facilities. Later, the policy acknowledges that clinical settings generally do not conform to laboratory BSLs.
Why inconsistent: Clinical settings are simultaneously included within a BSL-based definition and described as not conforming to BSLs. A separate definition of clinical research involving biohazards would avoid forcing clinical activity into a laboratory-containment framework.

86. N/A

I am responding: On behalf of myself

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Toxin scope and toxin oversight do not align
Scope covers “toxins” without an express threshold, but the definition limits toxin to a protein or peptide produced by living organisms that harms humans. Section IV-2 assigns full IBC review to Select Agent toxins, while Section IV-3 permits delegated review for non-Select Agent biological toxin proteins.
Unresolved points include:
• Whether all quantities and concentrations are covered.
• Whether inactive toxin derivatives are covered.
• Whether isolated subunits are “toxins.”
• Whether nucleic acids encoding toxins are treated as toxin research, genetic modification, or both.
• Whether low-toxicity proteins technically capable of harm require delegated IBC review.
• Why peptides are included in the definition but IV-3 refers only to “toxin proteins.”
This is a major administrative-burden issue because the literal language has no de minimis or potency threshold.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Animal hazards are treated inconsistently
The scope covers wild-type agents only when they cause disease in humans, which appears to exclude animal-only pathogens. Nevertheless:
• “Prions and self-aggregating proteins” include materials causing disease in humans or animals.
• “Zoonotic” agents are expressly defined.
• IBC membership must include animal-containment expertise under certain circumstances.
• The policy requires reporting incidents involving covered research animals.
• Risk assessment and containment provisions address animal populations and ABSL containment.
Result: The policy regulates animal-related procedures and environmental consequences, but its threshold definition may exclude the underlying animal pathogen unless it is zoonotic or genetically modified.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: genetically modified plants are expressly excluded. At a minimum, plants should be considered where a modification creates a plausible food/feed safety, agricultural, or environmental consequence.

This also feels like another example of the “dis-coordinated framework.” USDA, FDA, and EPA each regulate different aspects of biotechnology, while NIH sits somewhat outside that framework despite setting institutional expectations for federally funded research. Those agency authorities do not necessarily replace institutional oversight during the research phase.

If NIH intends to exclude plant research because other federal agencies provide sufficient oversight, that relationship and the handoff points should be explicit. Otherwise, the policy risks creating exactly the kind of regulatory gap the Coordinated Framework is supposed to prevent.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: “Biological agent” is defined too narrowly for how the term is used
The policy defines a biological agent as bacteria, viruses, fungi, or parasites that cause human disease. That excludes nonpathogenic organisms, animal-only pathogens, plant pathogens, and agents with uncertain pathogenicity. Yet later provisions repeatedly use “biological agent” when discussing RG1 materials, zoonotic agents, genetically modified agents, environmental impacts, and organisms not currently known to cause human disease.

I am responding: On behalf of myself

Name: Holda Ramos da Silva

Name of Organization: University of Maryland, Baltimore

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 9/29/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I do not think it makes sense that RG1 pathogens are not subject to the policy, while research involving transgenic organisms maintained at BSL-1/ABSL-1 would require oversight. I can understand requiring IBC review for the creation of transgenic animals; however, what happens when a PI simply purchases a transgenic animal and uses it solely for behavioral studies? Would an IBC protocol be required in that situation, and if so, for what purpose?

In these cases, there is little or no biosafety risk to human health, and any environmental concerns are already addressed through IACUC oversight and institutional animal care and housing programs. Requiring IBC oversight for such activities adds administrative burden without providing a corresponding benefit to safety.

In addition, if this research falls under IBC oversight, would each transgenic animal strain need to be reviewed and documented in the IBC minutes? The policy is unclear on how broadly these requirements would apply and what level of review would be expected.

I believe these issues should be clarified before the final policy is released. Clear guidance is needed regarding when IBC review is required for research involving transgenic animals, particularly when the animals are commercially obtained, maintained under ABSL-1 conditions, and used exclusively for studies that do not introduce new biosafety risks.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Including personnel records, training records, laboratory inspections, risk assessments, and occupational health

requirements in the minutes will greatly increase the time required to prepare them. I made a rough estimate of what would be required from our department, and this would increase the time spent preparing minutes by approximately 70%. It would require nearly a full-time position dedicated solely to producing the required minutes template.

While transparency is important, all of this information is already maintained by the IBC Office and can be provided at any time through a FOIA request. Requiring risk assessments and detailed discussions to be included in the minutes is also unnecessary, as this information is already documented in much greater detail within the IBC protocol itself. Using this template, I estimate that the minutes for each meeting could easily reach 70 pages in length.

The incident reporting templates appear reasonable to me. However, NIH should carefully consider the consequences of making this information publicly available. It would be very easy to identify an individual who experienced a workplace injury based on the information required in the First Report of Injury form. Depending on the pathogen involved, this could narrow the possibilities to only a few laboratories. This may cause embarrassment for individuals who were injured at work and result in unnecessary exposure of their personal information. I would not be surprised if this also increased the potential for future legal challenges or lawsuits.

6. Other feedback relevant to this resource: Instead of requiring Research with primary cells that may be contaminated by adventitious agents to undergo full committee review, this should be eligible for Designated Member Review (DMR). The risk assessment, bloodborne pathogen (BBP) training requirements, and PPE requirements for this type of research are already well established. Requiring full committee review would not provide a meaningful increase in safety and could delay research by up to six weeks while investigators wait for the next IBC meeting before beginning their work.

I also do not see a reason to eliminate exempt categories such as transgenic rodents housed under ABSL-1 conditions. Does this mean that all research involving transgenic mice housed at the institution would require IBC review, even when the biosafety risks and containment have already been assessed by IACUC? There is no increase in safety asking to a PI make an IBC protocol only for the use of a transgenic mice they didn't even create.

Please also clarify what constitutes a minor amendment under Section IV-3. For example, would the addition of a new genetically modified cell line be considered a minor amendment eligible for Designated Member Review (DMR) if it does not alter the risk assessment of a previously approved IBC protocol? In this scenario, the protocol has already undergone full committee review and received approval. If the proposed cell line does not introduce new hazards, containment requirements, or changes to the existing risk assessment, it is unclear whether the amendment would require full committee review or could be processed through DMR.

Clarification on this point would help institutions apply the requirements consistently and avoid unnecessary administrative burden when proposed changes do not affect the overall biosafety risk profile of an already approved protocol.

Re: Request for Comment — Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

I am a physician-scientist in the Division of Infectious Diseases at the University of Washington and Harborview Medical Center, and the Director of the Seattle Tuberculosis Research Advancement Center (SEATRAC). My laboratory conducts research on the immunology of *Mycobacterium tuberculosis*, a Risk Group 3 pathogen. I submit these comments in my individual capacity as a researcher working daily with the kinds of biohazards that would be most directly affected by this proposed policy.

1. Scope (Section II). I support the expansion of scope from recombinant and synthetic nucleic acid molecules to all biohazards, including wild-type biological agents that cause disease in humans, toxins, prions, and other self-aggregating proteins. The current framework creates an inconsistency in which work with unmodified, naturally dangerous pathogens, including *M. tuberculosis*, sits outside the formal federal biosafety oversight structure, while genetically modified derivatives of lower-risk organisms may require full IBC registration. This misalignment does not reflect actual risk and creates unnecessary administrative burdens. The proposed scope is more logically grounded in hazard-based reasoning and better reflects the breadth of contemporary biomedical research. I support this change.

2. Institutional Submissions to NIH (Section III-A). I support replacing the annual IBC registration requirement with a quadrennial institutional Biosafety Assurance, provided the intention is genuinely to reduce administrative burden on institutions and investigators. The assurance model used by IRBs and IACUCs has worked reasonably well, and aligning IBC oversight with that structure is sensible. I would encourage NIH to ensure that the assurance process is streamlined and that the documentation requirements do not in practice recreate the administrative load of annual registrations through a different mechanism. The framing of the assurance as a four-year commitment is welcome.

3. Incident Reporting (Section III-B). I have significant concerns about two elements of the proposed incident reporting framework.

24-hour reporting requirement. The draft policy would require institutions to notify NIH within 24 hours of becoming aware of incidents posing significant risk to human health, including all incidents at BSL-3/ABSL-3 and BSL-4/ABSL-4 containment. While I understand the intent to improve timeliness and situational awareness, I am concerned that this requirement is not calibrated to actual risk. In a BSL-3 research environment, the events most likely to trigger a reportable incident are often potential exposures for which the immediate medical and occupational health response appropriately takes priority over administrative notification. Diverting time and attention to preparing a report for NIH within 24 hours, often before full information is available, could interfere with the optimal management of the event itself. The existing 30-day window for most incidents has served institutions adequately. I would recommend retaining a 24-hour reporting threshold only for incidents with confirmed community risk or confirmed laboratory-acquired infections, and preserving a longer window for other categories of BSL-3/4 incidents where immediate risk to the public is not established. This is consistent with current practice.

Mandatory public posting of all incident reports. I also have concerns about the proposal to require all incident reports, including lower-risk events addressed entirely at the institutional level, to be posted on a public-facing institutional website. I understand and share the goal of transparency. However, the practical effect of requiring public posting of routine or low-risk incidents is likely to be counterproductive. For events that pose no meaningful risk to the community, the time and effort that investigators, IBCs, and communications staff will spend contextualizing and explaining these reports will substantially exceed the public benefit of avoiding misinterpretation by the public, the press, or local regulators. This burden will fall disproportionately on institutions without dedicated communications infrastructure and may create disincentives for thorough internal reporting and documentation. I recommend that mandatory public posting be limited to incidents that are reportable to NIH, and that lower-risk events addressed locally remain subject only to institutional record-keeping

requirements, consistent with current practice. NIH's proposed annual incident summary report would still provide meaningful public transparency at the aggregate level without the risks associated with real-time disclosure of routine events.

4. Lowering of Containment (Section IV). I support the proposed tiered approach to containment reduction, which would require NIH approval only for initial requests to lower containment for RG3 and RG4 agents, while delegating authority for RG2 lowering decisions to IBCs. For laboratories like mine working routinely with RG3 pathogens, the current requirement to seek NIH approval for all containment modifications creates bottlenecks that are disproportionate to the risk in cases where the IBC has already performed a thorough risk assessment. The proposed approach appropriately concentrates federal review where the risk and scientific uncertainty are highest, while reducing unnecessary friction for well-understood agents.

5. Delegated Review (Section IV-3). I support the introduction of delegated review for specified categories of lower-risk research. The current prohibition on delegated review means that IBC time and attention is not well-matched to the actual risk profile of the protocols under review. By permitting an individual member or a subgroup to approve routine, lower-risk protocols, such as work with well-characterized cell lines, non-Select-Agent toxins, or RG2 wild-type agents, the full committee can devote more substantive attention to the complex, higher-risk protocols that genuinely warrant it.

6. Alignment of IBCs with IRBs and IACUCs. I strongly support the proposal to formally establish IBCs as one of the three foundational pillars of institutional research oversight, alongside IRBs and IACUCs. In practice, biosafety considerations are often downstream of and informed by the IRB and IACUC review process, yet IBCs have historically lacked the institutional standing and resourcing that the other committees receive. Formalizing their role and ensuring consistency in oversight structures across these three bodies will benefit researchers, institutions, and public safety alike.

I appreciate the opportunity to provide comment and commend NIH for its extensive stakeholder engagement during the development of this proposal. I urge NIH to give particular attention to the incident reporting concerns raised above, as these represent the elements of the draft most likely to increase administrative burden without a commensurate improvement in safety outcomes.

Respectfully submitted,

Chetan Seshadri, MD
Professor, Department of Medicine
University of Washington School of Medicine
Director, Seattle Tuberculosis Advancement Center

Date Submitted: 9/30/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: 1. Exemptions: establish clearly defined exemptions for research that presents low/negligible or well-characterized biosafety risk. Removal of the existing exemption framework could unnecessarily increase IBC registration, review, documentation, and tracking requirements for activities that do not warrant continuing institutional oversight. The final policy should identify categories that are outside the Policy entirely versus activities that are covered but eligible for delegated review.

2. De minimis toxin exemption: establish a risk-based or de minimis exemption for biological toxin research involving quantities, concentrations, formulations, or experimental conditions that present negligible occupational or environmental risk. Requiring IBC review solely because a material meets the definition of a biological toxin may impose administrative requirements disproportionate to the actual risk.

3. Clarify whether toxins appearing on the Select Agent list but maintained below applicable Federal Select Agent Program exclusion quantities automatically require full IBC review, or whether quantity and actual risk may be considered in determining the appropriate review category.

4. Existing federal oversight: establish an exemption or formal recognition mechanism for research

already subject to equivalent biosafety oversight by another federal department or agency. Institutions should not be required to duplicate protocol review, inspections, incident investigations, training, corrective-action tracking, or other oversight when an existing federal program provides equivalent protections.

5. Well-characterized cell lines: why routine, well-characterized materials require an approval? Consider exempting well-characterized cell lines that have no identified biohazard beyond risks already addressed through established institutional practices. If NIH retains delegated review, the final policy should define "well-characterized" and explain the biosafety risk that necessitates prospective IBC approval.

6. Routine RG2 work with established containment: Consider whether every project really needs prospective registration. Consider whether routine work with well-characterized RG2 agents conducted at established BSL-2 containment under standard BMBL practices requires project-specific IBC approval, or whether institutions should be permitted to manage defined categories through approved institutional biosafety procedures and periodic compliance monitoring.

7. Primary human cells: Clearly define when primary human cells are considered potentially contaminated with adventitious agents and therefore require full IBC review. The final policy should clarify whether all primary human cells are presumed to meet this criterion or whether review is triggered by specific source, screening, donor, clinical, or other risk factors.

8. Compliance violations: Establish a clear significance threshold for NIH reporting of compliance violations. The phrase "any compliance violations at any BSL/ABSL" could reasonably be interpreted to require external reporting of minor administrative or technical deviations that present no meaningful increase in biosafety risk. NIH should distinguish significant or substantive violations requiring NIH notification from minor deficiencies that may be documented, corrected, and closed through institutional/IBC oversight.

9. Define minor amendments and identify administrative changes that do not require prospective IBC approval, such as changes that do not affect the agent, procedure, containment, exposure potential, or underlying risk assessment.

10. Clarify whether existing documented inspections performed under another federal biosafety program may satisfy periodic compliance-monitoring requirements when they evaluate equivalent requirements. Institutions should not be required to conduct duplicative inspections solely to satisfy separate administrative frameworks.

11. Three-year de novo review: NIH should permit streamlined continuing review for unchanged research with a demonstrated history of compliance rather than requiring complete de novo registration every three years. Full de novo review should be reserved for research involving substantive changes, increased risk, significant compliance concerns, or other defined triggers.

12. Public disclosure exemption for federal/security-sensitive facilities: NIH should establish a defined exemption or alternative transparency mechanism for federal institutions when public posting would

conflict with CUI, OPSEC, national-security, law-enforcement, proprietary, privacy, or other information-protection requirements. Institutions should not be placed in the position of reconciling conflicting federal obligations without clear NIH guidance.

15. Grandfathering existing research: Provide a transition or grandfathering mechanism for research already reviewed and approved under an established institutional or federal biosafety program when the new Policy becomes effective. Existing research should be permitted to continue through its current approval period unless a substantive risk issue requires earlier review.

16. NIH should consider whether institutions whose research portfolio consists exclusively or predominantly of activities eligible for delegated review should be required to maintain the same IBC infrastructure as institutions conducting research requiring full IBC review. For institutions conducting limited, low-risk BSL-1/BSL-2 research, NIH should consider permitting qualified institutional biosafety personnel or another designated institutional reviewer to conduct and document low-risk reviews without requiring establishment and continuing administration of a full IBC, provided defined criteria and escalation procedures are met. Alternatively, NIH should provide a streamlined IBC model for institutions with exclusively low-risk research portfolios, including reduced administrative, meeting, membership, and reporting requirements while preserving a mechanism for escalation to full IBC review when

17. NIH should permit qualified institutional biosafety personnel to document exemption determinations without requiring submission to the IBC for approval. NIH should provide objective exemption criteria and a standardized exemption-determination tool or checklist.

18. Oversight should be proportional to actual biosafety risk. NIH should reserve full and delegated IBC review for activities for which prospective committee oversight meaningfully improves biosafety, while using exemptions, programmatic approvals, reciprocity, and institutional determinations for well-characterized low-risk activities. This would allow institutional resources to remain focused on research and compliance issues presenting meaningful biosafety risk.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Blood cancers

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The new policy is a broad administrative over-reach that will impede progress in biomedical research and discovering new cancer therapies. The concept of reviewing every new reagent, synthetic nucleic acid, animal strain, cell line variant, etc. is NOT feasible. Implementation of this policy would create an enormous administrative burden for investigators and inspectors. As there is already inadequate funding for biosafety review officer this policy would simply increase the likelihood of less complete and thoughtful review of reagents I strongly advise AGAINST the proposed policy change.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Oversight should be local as these issues are complex and require real conversations between investigators and regulators to ensure safety and compliance. Federal oversight of local inspections is appropriate but too slow to review biosafety in a timely manner.

3. Continued utility of Risk Groups: Biosafety levels are well established and should be the standard approach.

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 9/30/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer immunotherapy, cellular therapy, translational research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Scope captures a very large volume of low-risk work. Under Section II, any research involving genetically modified cells, viruses, or organisms other than plants is in scope. In practice, essentially every molecular biology, immunology, and cell biology laboratory at an NIH-funded institution now requires registered, approved oversight. Section IV-3 confirms this: delegated review is still required review for plasmids, replication-incompetent non-integrating vectors carrying reporter transgenes, well-characterized cell lines, and genetically modified RG1 agents. A graduate student transfecting a GFP plasmid into HEK293T cells is now performing registered research.
The cost is not the review itself. It is the registration, amendment, renewal, and audit infrastructure that must be built and maintained around tens of thousands of protocols posing negligible risk. NIH should establish a genuine exempt category defined by the characteristics of the construct and host, rather than requiring a submission to confirm exemption. Work with replication-incompetent, non-integrating vectors expressing non-toxic, non-oncogenic transgenes in established cell lines at BSL-1 should be documented locally and require no IBC action.
Section III-B separately caps approvals at three years and requires de novo submission thereafter. For a laboratory with a stable platform, this converts a one-time registration into a perpetual cycle of rewriting unchanged documents, while genuinely new risk is already captured by the existing requirement to review amendments affecting the biosafety assessment. Administrative continuation with attestation of no material change would be sufficient, reserving de novo review for BSL-3/4 work, GDMOs, and substantively modified protocols.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The draft's architecture is sound: tiered review calibrated to risk is the right model. The problem is that the tiers, as drawn, place far too much ordinary laboratory work under mandatory review and attach to it a recurring apparatus of re-registration, public posting, redaction, and reporting, whose cost is borne continuously by every NIH-funded institution.
I would urge NIH to:
1. Define a true exemption for low-risk constructs, not a submission that confirms exemption.
2. Replace de novo renewal with attestation for stable protocols.

3. Limit mandatory public posting to annual institutional summaries.
4. Reserve 24-hour reporting for genuine safety events.
5. Commit to a binding timeline for the federal approvals it is newly requiring.
6. State that IBC review of FDA-regulated INDs is confined to containment and handling.
These changes would preserve the policy's safety gains while keeping faith with the commitment to streamline, not accumulate, administrative processes. Thank you for the opportunity to comment.

3. Continued utility of Risk Groups: Regarding NIH's specific question, Risk Groups remain useful as a property of the agent, distinct from BSL, which is a property of the work; Section V-E states this correctly. The practical gap is that the draft gives no framework for how a genetic modification moves an agent between groups, then routes any containment reduction for RG3/RG4 agents through NIH. Published, searchable precedents from prior NIH determinations would reduce burden more than any other single implementation resource, by letting IBCs act locally on constructs NIH has already evaluated.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reporting conflates administrative lapses with safety events. Section III-B requires 24-hour notification to NIH, with a full report within 30 days, for any compliance violation at any BSL, including failure to obtain or maintain IBC approval. A lapsed registration renewal on a BSL-1 plasmid protocol is thereby placed in the same channel, on the same clock, as a laboratory-acquired infection.
This dilutes the signal NIH is trying to collect and consumes staff time on paperwork errors. Because these reports must also be publicly posted, it creates a strong incentive to under-report rather than to self-identify and correct. The 24-hour channel should be reserved for events involving actual or potential exposure, containment loss, or public health consequence, with administrative non-compliance handled through routine institutional reporting and the annual summary.

6. Other feedback relevant to this resource: Section IV-1 requires NIH approval, in addition to IBC approval, before initiating research involving emerging, novel, or zoonotic agents lacking a BMBL classification, and for initial requests to lower the containment level for RG3/RG4 agents. Section III-D commits NIH only to reviewing these in a timely manner. For translational programs operating against IND timelines, manufacturing slots, and enrollment windows, an open-ended serial federal review is a material risk. If NIH inserts itself into the critical path, it should commit to a defined 30-day response interval and specify a consequence if that interval is not met.
Section IV-2 separately brings under IBC review the administration of products capable of shedding, replicating, or integrating. That describes every lentivirally transduced cell product and every in vivo gene therapy now in clinical development, all of which are already reviewed by FDA under IND, by the IRB, and by institutional scientific review. Section II says research under another agency's purview may proceed once that agency's approvals are obtained, but Section IV-2 then requires IBC approval before initiation, which is at minimum ambiguous and will be read conservatively. NIH should state plainly that for FDA-regulated INDs, IBC review is confined to containment, handling, waste, and shedding precautions, and does not re-adjudicate product risk, construct design, or clinical protocol.

Quorum: Requiring at least two unaffiliated voting members, alongside expanded scope and far greater protocol volume, will make quorum the rate-limiting step at many institutions. Unaffiliated members are

volunteers with finite availability. If the requirement is retained, NIH should permit alternates, remote participation, and counting a single unaffiliated member toward quorum where a second has provided a written review.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The broadened scope will increase administrative burden, not necessarily for the committee itself, but for the staff who support it. While potentially cutting committee meeting times, delegated approvals will be time consuming for the delegate/delegates. Shifting the burden does not decrease the burden.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Section III-A
IBC records retention period should not be tied to the date of a financial report that does not get reported to the IBC. This will rely on systems run by other offices. Please specify which IBC documents will be held to this retention period. Only those shared with the grants office, such as approval letters, or all?

Section III-B
Guidance is needed on what identifies a registration as de novo rather than a renewal of the same work. Will committee review reflected in the minutes be enough?

Section III-B
IBC membership states that the IBC should include individuals with expertise in biological safety and physical containment. The duties of the BSO are listed and must be assigned to another official if there is no BSO. Please provide guidance about the expectations for these individuals' training, certifications and experience.

Section III-C
Strengthen the requirement to report any subsequent changes to include all. The PI may not consider something an alteration of biorisk when it may, in fact, be one. The IBC will not have an opportunity to review it until is discovered at an annual review or inspection.

The responsibility of reporting to the NBDSAC should fall to the IBC not the PI.

Section IV-3
This section must more clearly state that a delegate/delegates can review and approve all the bulleted items as an initial submission and as amendments to full committee approved submissions, if this is what was intended.

104. West Virginia University Institutional Biosafety Committee

I am responding: On behalf of an organization

Name:

Name of Organization: West Virginia University Institutional Biosafety Committee

Type of Organization: Institutional Research Oversight Committees e.g. IRB

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/1/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): biomedical research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We support expanding oversight beyond recombinant DNA research to encompass the broader range of biohazards encountered in modern biomedical research. The proposed scope aligns well with the oversight currently performed by our IBC and better reflects today's research landscape. However, NIH should provide additional clarification regarding key definitions, particularly those related to Gene Drive Modified Organisms (GDMOs), to ensure consistent interpretation and implementation across institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed risk-based oversight structure is appropriate, but NIH should carefully evaluate the administrative burden associated with the expanded transparency, reporting, and documentation requirements. For smaller biosafety programs, maintaining public websites, publishing meeting minutes and incident reports, and managing Biosafety Assurance requirements may require substantial additional resources. For our institution, these responsibilities would largely fall to a biosafety office consisting of only two full-time professionals who are also responsible for protocol review, laboratory inspections, training, incident response, risk assessments, and researcher support. NIH should provide standardized templates and tools to support implementation and clarify the responsibilities of the Authorized Organizational Representative (AOR). Oversight requirements should remain proportional to risk and should not detract from core biosafety functions such as laboratory support, risk assessment, and training.

3. Continued utility of Risk Groups: Risk Groups should remain an important component of the risk assessment process, but Biosafety Levels should continue to serve as the primary framework for determining containment requirements. BSL assignments more accurately reflect the engineering controls, work practices, and facility features necessary to mitigate risk. NIH should continue encouraging institutions to consider agent characteristics, genetic modifications, experimental procedures, and exposure potential when determining appropriate containment. Additional guidance regarding expectations for microorganism inventories would also be beneficial.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH can encourage voluntary adoption of the policy through the development of practical implementation resources, model policies, templates, and training materials. Institutions are more likely to adopt recommended practices when expectations are clearly defined and implementation is straightforward. Transparency requirements should be balanced against the risk that scientific or biosafety information may be misinterpreted by individuals lacking relevant technical expertise, potentially resulting in public misunderstanding or unnecessary concern.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed templates provide a useful framework, but NIH should provide additional guidance regarding acceptable redactions and protection of sensitive information, including personnel, grant, and clinical research information. Public disclosure requirements may have unintended consequences if researchers perceive that reporting incidents or near misses could result in public scrutiny, potentially discouraging timely reporting. NIH should also reconsider the proposed 24-hour reporting requirement and allow sufficient time for institutions to perform an initial assessment before submitting a report. Incident reporting should be coordinated through institutional biosafety programs rather than individual investigators to ensure consistency and accuracy.

6. Other feedback relevant to this resource: Additional guidance will be essential for successful implementation. Areas that would benefit from further clarification include definitions and oversight expectations GDMOs, AOR responsibilities, Biosafety Officer qualifications, microorganism inventory expectations, incident reporting procedures, and standards for publicly posted information. Institutions with limited biosafety staffing will require practical implementation tools and sufficient time to develop compliant processes. For a biosafety office staffed by only two professionals, implementation of new website management, public posting requirements, expanded documentation, and additional reporting obligations may require significant operational changes and could divert resources from direct biosafety oversight activities. The proposed six-month implementation period may be insufficient given the scope of the required changes, and NIH should consider a longer transition period.

Overall Comment
The draft policy represents a thoughtful and necessary modernization of biosafety oversight and appropriately expands beyond the historical focus on recombinant DNA research. Successful implementation, however, will depend on clear definitions, practical guidance, realistic implementation timelines, and balancing transparency with administrative feasibility. NIH should ensure that new requirements strengthen biosafety oversight without diverting limited institutional resources away from the primary goal of identifying, assessing, and mitigating biological risk. This consideration is particularly important for institutions whose biosafety programs operate with small staff and limited administrative support.

105. Matt Stinoski

I am responding: On behalf of myself

Name: Matt Stinoski

Name of Organization: West Virginia University

Type of Organization: Institutional Research Oversight Committees e.g. IRB

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/1/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): biomedical research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As a Biosafety Officer, I support expanding oversight beyond recombinant DNA research to encompass the broader range of biological hazards encountered in modern biomedical research. The proposed scope more accurately reflects the work currently performed by institutional biosafety programs and aligns oversight with today's research landscape. However, additional clarification is needed for several key definitions, particularly those related to Gene Drive Modified Organisms (GDMOs), to ensure consistent interpretation and implementation across institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed risk-based oversight framework is appropriate and helps align regulatory requirements with potential risk. However, NIH should carefully consider the administrative burden associated with expanded transparency, reporting, and documentation requirements. For many institutions, particularly those with small biosafety programs, responsibilities such as maintaining public websites, publishing meeting minutes and incident reports, and managing Biosafety Assurance requirements may require significant additional effort and resources.
As a Biosafety Officer, I am concerned that these requirements could place substantial demands on programs that are already responsible for protocol review, laboratory inspections, training, incident response, risk assessments, and day-to-day support of researchers. NIH should provide standardized templates, implementation tools, and clear guidance regarding the responsibilities of the Authorized Organizational Representative (AOR). Oversight requirements should remain proportional to risk and should not divert resources from core biosafety activities that directly support safe research

3. Continued utility of Risk Groups: Risk Groups should continue to play an important role in the risk assessment process, but Biosafety Levels should remain the primary framework for determining containment requirements. Biosafety Levels more directly reflect the engineering controls, laboratory practices, and facility features needed to mitigate risk. Institutions should continue to evaluate agent characteristics, genetic modifications, experimental procedures, and potential routes of exposure when determining appropriate containment. Additional NIH guidance regarding expectations for microorganism inventories would also be helpful, as practices currently vary across institutions.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH can promote voluntary adoption of the policy by developing practical implementation resources, model policies, templates, and training materials. Clear expectations and readily available tools will make implementation more achievable and consistent across institutions. While transparency is important, public disclosure requirements should be balanced against the possibility that highly technical scientific or biosafety information may be misunderstood by individuals without relevant expertise, which could result in unnecessary concern or misinterpretation of institutional activities.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed incident reporting and meeting minutes templates provide a useful starting point. However, additional guidance is needed regarding acceptable redactions and the protection of sensitive information, including personnel information, grant-related data, proprietary research details, and clinical research information. Transparency should not inadvertently compromise confidentiality or institutional interests.
I also encourage NIH to reconsider the proposed 24-hour reporting requirement and allow institutions sufficient time to conduct an initial assessment before submitting a report. Rapid reporting is important, but accuracy and context are equally critical. In addition, incident reporting should be coordinated through institutional biosafety programs rather than individual investigators to ensure consistency, completeness, and appropriate risk evaluation.

6. Other feedback relevant to this resource: Successful implementation will depend on the availability of clear guidance and practical resources. Areas that would benefit from additional clarification include GDMO definitions and oversight expectations, AOR responsibilities, Biosafety Officer qualifications, microorganism inventory expectations, standards for publicly posted information, and incident reporting procedures.
From the perspective of a Biosafety Officer, institutions with limited staffing will need sufficient time and resources to develop compliant processes. Requirements related to website management, public posting, expanded documentation, and additional reporting obligations may necessitate significant operational changes. The proposed six-month implementation period may be insufficient given the scope of these requirements. A longer transition period would allow institutions to implement changes thoughtfully and effectively while maintaining focus on their primary mission of biological risk assessment and mitigation.

Overall Comment
Overall, the draft policy represents a thoughtful and necessary modernization of biosafety oversight and appropriately expands beyond the historical focus on recombinant DNA research. As a Biosafety Officer, I support the intent of the proposed framework and its emphasis on risk-based oversight. The success of the policy, however, will depend on clear definitions, practical implementation guidance, realistic timelines, and a balanced approach to transparency.
NIH should ensure that new requirements strengthen biosafety oversight without creating administrative burdens that could divert limited resources away from essential biosafety functions, including risk assessment, laboratory support, training, inspections, and incident response. This consideration is particularly important for institutions whose biosafety programs operate with small staffs and limited administrative support.

106. Catherine H. Schein

I am responding: On behalf of myself

Name: Catherine H. Schein

Name of Organization: University of Texas Medical Branch

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 10/1/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Allergy and virus epitopes, immune reaction to proteins

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The document did not specificy that the purpose is to control BSL level pathogens. It needs a mention that work with normal expression plasmids (where a single non-pathogenic protein is cloned) and expressed in auxotrophic bacteria (like E.coli K12 strains and yeast cloning strains) do not require approval.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): While the protections in the document for BSL-3 and -4 organisms are approximately what is in use today, it seems as if the document is trying to apply the same level of "approvals" for organisms that pose no threat and research that is today conducted in a BSL1 or 2 lab. This is an unneeded extension of current practice that will add to the time before a project can start and is likely to increase still more indirect costs

3. Continued utility of Risk Groups: Again, why? What is wrong with the current BSL designations, that are copied all over the world.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): BSL precautions are applied in our institution, regardless of where the funding comes from.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reporting seems a bit vague; it has been pointed out that a researcher having a paper cut or other minor injury (say from a glass flask breakage in the autoclave) in the course of work would have to report it as an "incident".

6. Other feedback relevant to this resource: Look, this document is long enough and so vaguely written that one would wonder if any research project can be started. We should not need a higher level of reporting than we currently have.

107. N/A

I am responding: On behalf of myself

Name:

Type of Organization: Not Applicable

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/1/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Some definitions of biohazards are vague and not in line with the common scientific definitions, which allows for multiple interpretations. The proposed policy is ~ 20 pages long and many terms are overly simplified from the previous (almost 10 times longer) guidelines, which pertained only to nucleic acids. The previously used guidelines had clear definitions and examples of research under different categories, which are lacking from the policy draft.
As an example, under "genetic modification" definition there is a bullet point with "Can be transcribed or translated", which, while uses certain nucleic acid does not generally modify the genome of the cell and, thus, should not be defined as genetic modification. This can create the situation when previously exempt substances (e.g. most of the siRNAs and mRNAs) that were proven as safe over the years fall under the new policy.
Definitions of cells containing covered hazards is also very vague. As an example- should a commercially available cell line with a stable modification for a reporter protein (e.g. luciferase or GFP) fall under the new policy?
The definitions of toxins are also very vague and do not represent thresholds for concentrations, quantities, etc. It would be beneficial to provide a concrete list of toxins with thresholds. Otherwise multiple proteins can be considered "toxins".
Additionally, the definitions of "biomedical research" and "potential risk" are unclear. These can be clarified with examples. In terms of "potential risk"- thresholds should be added to the policy or it should be under institutional oversight (should be specified in the policy).
It is unclear which agency can determine "non-compliance with the policy".
In terms of the oversight, it is unclear who at NIH approves AOR (if this requires approval) and how the Institutional Assurance is submitted and approved, is there a template? what information should be included, etc. What are the criteria for approval/disapproval/withdrawal of approval of assurances?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Vague definitions of "low risk incidents and minor spills".
It is unclear why no BSO is required on the IBC committee for BSL2 work.

While delegated review process is a positive change, guidance and clarifications on the delegated review process should be included.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Transparency requirements and public posting of the incidents are very broad and can impose a significant burden (e.g. reporting within 24h) as well as may potentially cause lack of reporting.
Multiple terms in "reporting" are not defined clearly. As an example "potential release" and "compliance violation" should be defined more specifically.
In many institutions a staff member involved in any incident is directed to the employee health clinic- is this automatically considered a "treatment beyond first aid"?

Comments on Draft NIH Biosafety Policy for Research Involving Biohazards

I would like to thank the NIH for providing the biosafety community the opportunity to provide comments on the draft NIH Biosafety Policy for Research Involving Biohazards. As a biosafety professional for over 32 years, I take this very seriously in the hopes of developing a scientifically strong regulatory policy that benefits the safety and compliance of the life science programs in an effective and strategic manner. Below please find my comments.

POLICY

- During all the listening sessions, the regulated community asked over and over again to deregulate the non-hazardous rDNA research. There is no scientific justification for its oversight by the IBC after all these many years of safe research. Instead, this new policy now regulates it even more; there is no longer an exempt category of research, and even ABSL1 transgenic rodents are no longer exempt. All of these materials should be excluded from the new regulations.
- I am also disappointed that there is no alignment of the various regulations from the different federal agencies with this new regulation as was discussed in the listening sessions. The OSHA BBP Standard is barely mentioned though it is definitively entwined within the proposed regulations. The Federal Select Agents are hardly mentioned, as are the USDA and CDC permit programs and the new USG Stopping Policy. During the listening sessions the introductory presentations stated the hope to bring these numerous policies from numerous agencies into alignment within one source, to make compliance easier for the regulated community. Based on the draft policy, research institutions must still answer to numerous separate regulations and regulatory bodies.
- I am strongly supportive of the ability to utilize delegated reviewers for low-hazard research now. This will streamline reviews and improve turnaround time for review committees and the PIs.
- I find it very curious that agricultural pathogens, and plants in particular, have been excluded from the regulations; environmental impact is just as significant a problem in the realm of global One Health as human health concerns.
- The question is raised as to why a Biosafety Officer is only required for research at Biosafety Level 3 and 4. It should be required at least at BSL2, as well as for any agency utilizing Federal Select Agents within this policy.
- In regards to the IBC Committee Members, please provide a clearer definition of the member who is “not affiliated with the institution” as this definition has been inconsistent over numerous years under the existing NIH *Guidelines*, and different applicants reaching out to the NIH registering their IBCs have received different interpretations, making it very difficult to identify candidates to meet this requirement. The definition of institutional affiliation still remains murky and inconsistent.
- In regards to the posting of incidents on the website, no requirement for the length of time the incidents must be posted is provided.
- The posting of incidents on the website and at the NIH site, even if anonymized, may risk the confidentiality of the involved individuals, especially when listing the organism involved if they are rare or unusual, or if the work is unique.
- The posting of incidents on the website and at the NIH site, even if anonymized, may place the institution and/or the research group at risk of protests or targeting from activist groups.
- Though the intention of posting incidents is to provide more information on the types of incidents that occur and to determine ways to prevent them in the future, the exact opposite may occur if researchers are afraid to report incidents due to the posting requirement. This may lead to worse outcomes for the potentially exposed individual and less opportunity to prevent future incidents. Researchers will be more likely to hide incidents and fail to report them, leading to potential

complications for their injuries and impeding the goal of corrective actions to prevent future incidents.

- I recommend limitations to the types of incidents that must be reported and/or posted. For example, only incidents with BSL2 agents or higher should be reported, or only if a true health risk or exposure occurs. For example, is it necessary to report a spill of a microtainer tube of an agent within a functioning biosafety cabinet, where the personnel are wearing PPE, and the spill is cleaned up properly right away? Is this really a release? There is no benefit of calling this a spill or release, or of reporting or posting this incident. Reporting a situation like this, where everything worked properly and no one was exposed benefits no one.
- The duties identified as belonging to the Biosafety Officer should be able to be delegated to other members of the biosafety staff. Lab inspections, incident investigations, and technical advice are often provided by other members of the biosafety team working under the Biosafety Officer, and the duties assigned to the BSO in this policy, along with what is typically required of the Biosafety Officer, are too extensive to be performed by just one person, especially at larger institutions that also have other regulatory programs, such as select agents, high containment labs, USDA or CDC programs, BBP programs, etc. The ability to delegate these activities should be stated in the policy.
- Would the Biosafety Officer be expected to serve on each Delegated Review team? Or could a representative from the biosafety team serve on these teams, or would they even be required on the Delegated Review team? The constitution of the delegated review teams is not made clear in the policy; if there are requirements to the constitution it should be specified within the policy. If a biosafety professional must serve on a delegated review team, other members of the biosafety team besides the Biosafety Officer should be able to serve this function.
- The PI should be able to assign a delegate to work under his/her oversight to assist with their responsibilities assigned within the policy; this should be clarified within the policy.
- Toxins need to be better defined- this is too broad. What is the LD50? Not all are proteins or peptides.
- Is the AOR empowered, or is the position just a contact/liaison for the institution? This needs to be defined. If it just serves as a contact/liaison, just call it such- it could be a duty of the IBC Administrator or BSO. If they must be empowered, we must know this to determine what authority the individual must have.
- The requirement to post minutes “for the length of time of the award’s final financial report” is almost impossible for any institution to track and maintain, as this is maintained by a separate office, and multiple protocols with different awards are listed in each set of minutes. Just require a set length of time, like the 5 years otherwise required to be a feasible option for posting and to minimize the recordkeeping burden on the offices.

INCIDENT REPORTING TEMPLATE

- On the form, in the question regarding whether the incident has been reported to other agencies, N/A should be an option.

Sincerely,

Krista Murray, MS, RBP, CBSP

119. Frances Lund

I am responding: On behalf of myself

Name: Frances Lund

Name of Organization: University of Alabama at Birmingham (UAB)

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/5/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): infectious disease and immune host defense

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed policy seems appropriate to cover the relevant biohazards.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Agree with the tiered oversight

3. Continued utility of Risk Groups: Risk groups are relevant place to start but seems that the genetic modification (and type of genetic modification) is most relevant to the conversation as to whether RSG should stay same (eg inserting a reporter like EGFP or a peptide sequence that can be followed but doesn't encode a protein), go up (modification that may increase virulence or introduces new proteins etc to the organism) or go down (attenutation, replication deficient etc). The composition of the IBC is most critical as this group makes the initial "call". Seems like there may be value in having online training for new IBC members (and having online training come from NIH so that it's very clear what the policies will be). The community members on the committee need to be there but there also needs to be sufficient training for those individuals to be able to thoughtfully look at risk levels. Not enough knowledge could lead to polar opposite results - things are not approved because they seem dangerous, even though risk is either low or can be appropriately managed or everything gets approved because the members can't identify the potential risks.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: I am most concerned about the required re-approvals. I think that it is fine that our biosafety reviews need to be reapproved every 3-4 years. However, I think that then Biosafety approval should be at the lab level rather than project level. Otherwise, it becomes very difficult to address 'changes". If it is done at the project level, then one project that is under review might have to change protocols etc but the other project that is not under review (yet utilizes the same genetically altered organism) would still be approved because it hasn't been re-reviewed yet. If we

register all our biosafety RGS under one protocol (and amend if we add new organisms)then all projects would have a consistent set of metrics that need to be followed. Mistakes and non-compliance occur most frequently when the rules are not evenly applied.

120. GeneConvene Global Collaborative, Foundation for the National Institutes of Health (FNIH)

I am responding: On behalf of an organization

Name: brinda dass

Name of Organization: GeneConvene Global Collaborative, Foundation for the National Institutes of Health (FNIH)

Type of Organization: Other

Type of Organization - Other: NGO

Role: Other

Role - Other: Technical Expert- Gene Drive Policy

Date Submitted: 10/5/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Genetically Modified Organisms- engineered gene drive organisms particularly mosquitoes, Vector borne diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed policy's focus on the safe conduct of laboratory research is appropriate. NIH should, however, clarify the scope and definition of biohazards to ensure that oversight is proportionate to the risks of the proposed activity and does not unnecessarily impede research on emergent use cases e.g., gene drive mosquitoes or their progression toward potential public-health use.

The presence of a genetic modification or gene drive should not, by itself, constitute a finding that an organism presents an unacceptable risk or requires heightened federal oversight. NIH should distinguish eligibility for biosafety assessment from the outcome of that assessment. Research involving gene drive mosquitoes can appropriately undergo institutional review without presuming that every organism, experimental activity, or research stage presents the same hazards.

The definition of biohazards should require a scientifically plausible basis for concern, informed by the organism's characteristics, the proposed activity, and scientifically credible exposure pathways. References to potential risk should not be interpreted as requiring investigators to eliminate every hypothetical uncertainty. Equally, the absence of a documented adverse effect should not be treated as proof of safety. Information requirements should address uncertainties that could materially change the biosafety decision.

NIH should clarify the treatment of pathogen-free mosquitoes, isolated molecular components, nonviable specimens, and constructs that cannot support gene drive activity under the proposed conditions. These materials and activities should not automatically receive the same oversight as work involving viable organisms capable of transmitting a drive. Clear exclusions, delegated review, and incorporation of existing assessments should be available where justified by the activity's risk. Such determinations should account for whether components could acquire relevant functionality in the

proposed experimental context.
The policy should preserve its explicit exclusion of deliberate/ intentional environmental release. Laboratory biosafety approval should neither authorize deployment nor create a duplicative NIH release-approval process. Field testing and public-health use should remain subject to applicable regulatory and federal, state and local requirements (including those on tribal lands). NIH should clarify how enclosed outdoor and semi-field studies are classified and how relevant determinations by other competent authorities may be recognized.
Any inadvertent oversight gaps should be addressed narrowly. In particular, NIH should reconcile the human-health threshold with consideration of environmentally consequential accidental escape from contained research. This can be achieved through targeted guidance on plausible exposure and adverse-effect pathways, rather than a general expansion of NIH oversight to all environmental effects or all uses of genetically modified organisms. Gene drive mosquitoes should not automatically be treated as novel pathogens merely because they are genetically engineered or lack a listing in a pathogen reference document.

We recommend that NIH expressly state: “Inclusion within the scope of this policy does not establish a presumption of high risk. The level of review, information required, and conditions imposed shall be proportionate to the proposed activity and supported by a documented risk assessment. NIH and institutions shall use the least burdensome oversight sufficient to manage identified scientifically plausible harms to mitigate related risks and shall avoid duplicative review.”

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): GeneConvene supports tiered biosafety oversight where the level of review is proportionate to the risks of the proposed activity. Institutional review should ordinarily be sufficient for contained gene drive mosquito research when an appropriately qualified committee can assess the relevant risks and establish effective safeguards. Federal review should be reserved for clearly defined circumstances requiring additional scrutiny or a nationally consistent determination.

NIH should clarify that genetic modification, gene drive capability, novelty, or uncertainty alone does not establish a need for federal escalation. Escalation should identify the specific concern, its significance for the proposed research, and why institutional review is insufficient. The framework should also provide explicit pathways to reduce administrative burden as evidence accumulates, including delegated review, incorporation of previous assessments, and reliance on materially applicable determinations.

For international research, NIH should clarify funding-related responsibilities, recognize equivalent oversight arrangements where appropriate, and support access to shared scientific expertise. Reviews should be coordinated to avoid duplication while preserving assessment of local facilities and environmental conditions.

Laboratory oversight categories should not become additional authorization requirements for field trials or public-health deployment particularly for international authorities or funders who could treat NIH’s laboratory categories as universal risk classifications or prerequisites for release. That would be an interpretation beyond this policy’s laboratory purpose. Those decisions should remain with the applicable competent authorities so as not to delay laboratory approval of research and prolong the pathway to use. With these clarifications, tiered oversight could support safe research and responsible

progression toward use; without them, ambiguous escalation and overlapping requirements could impose delays disproportionate to the risks.

3. Continued utility of Risk Groups: Risk Groups (RGs) remain useful as an initial reference for assessing infectious agents, including parental agents that undergo genetic modification. Their utility is limited, however, for organisms whose principal biosafety concerns involve escape, establishment, inheritance, or ecological effects. NIH should therefore retain RGs as one input where scientifically applicable, rather than use them as a universal classification system for genetically modified organisms.

RGs, Biosafety Levels, and Arthropod Containment Levels should be clearly distinguished. RGs describe agent hazards; BSLs and ACLs describe combinations of safeguards selected for particular activities. These systems are not interchangeable, and their numerical designations do not establish equivalent risk or containment. Genetic modification should prompt assessment of its functional consequences, without an automatic assumption that it increases risk.
For gene drive mosquito research, NIH should explicitly recognize the Arthropod Containment Guidelines and their gene drive addendum as complementary to BMBL. Assessment should integrate any pathogen-related hazards with mosquito biology, the modification, experimental procedures, and the consequences of unintended escape in the local environment. A containment requirement should not be interpreted as assigning the mosquito to a corresponding pathogen Risk Group.

To support consistent international implementation, NIH should provide worked examples, a terminology guide, and a crosswalk explaining how relevant BSL and ACL safeguards satisfy policy requirements. Such a crosswalk should compare specific measures rather than imply automatic equivalence between levels. Guidance should also distinguish laboratory containment decisions from the environmental risk assessment and authorization required for deliberate field testing or deployment.

This approach would preserve appropriate safeguards while reducing unnecessary escalation, duplicative facility requirements, and inconsistent interpretation across research institutions and national authorities.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary adoption through practical support, accessible expertise, and recognition of equivalent biosafety arrangements which would need to be assessed. The final policy should distinguish informal adoption of its principles from formal voluntary participation and clearly explain the obligations associated with each. Institutions outside mandatory coverage should be able to understand whether participation entails an Assurance, reporting requirements, or other administrative commitments before enrolling.
NIH should preserve and update the voluntary-compliance mechanisms in Section IV-D of the existing NIH Guidelines, including access to institutional biosafety review, requests for relevant determinations, and procedures for handling proprietary information. Implementation resources, training, and scientific consultation should be available to institutions regardless of their funding source.
For international gene drive mosquito research, voluntary participation should accommodate national legal frameworks, institutional structures, and access to shared or regional expertise. NIH should recognize scientifically justified equivalent safeguards and existing assessments, while retaining consideration of local facilities and environmental conditions. Documentation requirements should be

proportionate to the proposed activity and explicit about handling of proprietary information and confidential materials, public disclosure and incident learning information.

Voluntary participation should support institutional capability and confidence in biosafety practice. It should not become an additional authorization requirement for research, collaboration, field testing, or deployment otherwise governed by competent authorities. NIH should also clarify that participation does not constitute product endorsement or environmental-release approval. These measures would encourage broader uptake while avoiding unnecessary duplication and administrative barriers.

Comments on the draft NIH biosafety policy

Gene drive organisms and emerging synthetic biology

To: Office of Science Policy, National Institutes of Health
Re: NOT-OD-26-112
Date: September 30, 2026

Thank you for the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. These comments support rigorous biosafety oversight and recommend changes that would make review scientifically defensible, proportionate, and predictable across gene drive organisms and emerging synthetic biology. The central recommendation is to connect oversight and information requirements to plausible pathways to harm, the proposed research activity, and uncertainties that materially affect the decision.

NIH should preserve robust containment and independent review while avoiding automatic escalation based solely on a technology label, lack of a conventional comparator, or absence from a pathogen reference list. Equally, where a credible potential for severe or widespread harm cannot be adequately bounded, uncertainty should justify additional evidence, federal consultation, or a decision not to proceed. These complementary principles would support responsible innovation without weakening protection of personnel, communities, animals, plants, or ecosystems.

1 Preserve existing safeguards and improve the risk assessment method

The proposal addresses laboratory research rather than deliberate field release. Section V includes likelihood, severity, procedures, genetic modifications, and mitigation. These are appropriate foundations. [1] Existing NIH guidance already establishes Level 2 minimum containment for gene drive modified organisms (GDMOs), NIH approval for reductions, biosafety officer participation, and access to relevant ecological expertise. Those safeguards should not be presented as newly introduced restrictions. [2,3]

Biosafety in Microbiological and Biomedical Laboratories (BMBL) emphasizes protocol-driven assessment, expert review, and periodic reassessment. The World Health Organization (WHO) likewise recommends an evidence- and risk-based approach. [4,5] NIH should make the following sequence explicit: identify protection goals and assessment endpoints; formulate plausible pathways to adverse effects; evaluate relevant evidence and exposure; characterize likelihood, consequences, and uncertainty; select controls; and document residual risk and the basis for its acceptability. The Convention on Biological Diversity (CBD) gene drive guidance offers a useful problem-formulation framework. Its environmental-release focus could be adapted to the laboratory decision at hand, without importing field-release requirements wholesale or implying that the guidance creates any United States legal obligation. [6,7]

NIH should permit qualitative, semiquantitative, or quantitative assessment as justified by the evidence. Numerical probabilities should *not* be required where they would convey false precision. Conversely, general statements that harm is conceivable should not alone justify unlimited data requests. Each request should identify the decision-relevant uncertainty it is intended to resolve. The assessment should distinguish uncertainty due to missing knowledge (epistemic) from biological and natural variability (aleatory) and identify conditions under which the decision would change.

Suggested language: Risk assessments shall be case-specific and proportionate to the proposed activity, organism or biological system, and plausible exposure pathways. They shall identify protection goals,

potential adverse effects, relevant evidence, and uncertainties material to the decision. Information requirements and safeguards shall be justified by their relevance to those pathways. Assessors shall document residual risk, the basis for its acceptability, and conditions requiring reassessment. Initial conservative assumptions shall be revised when reliable evidence supports revision.

2 Tailor gene drive review to biological properties and research stage

Section V-B makes broader GDMO assessment mandatory; the existing Guidelines use a discretionary formulation. [1,2] NIH should clarify that mandatory consideration does not mean an identical, expansive evidence package for every project. The appropriate breadth should follow the drive system, organism, facility, surrounding environment, scale, and research stage.

NIH implementation materials already distinguish spread, persistence, ecological consequences, and biological and environmental containment. [3] Retaining these distinctions would help reviewers avoid treating all gene drives as equivalent. Guidance should encompass vertebrates, invertebrates, fungi and other microorganisms, and clarify the treatment of plant applications. It should distinguish an organism capable of drive activity from an isolated component, a nonfunctional construct, and a conventional genetically modified organism without inheritance bias. Claims of localization or self-limitation should be assessed rather than presumed.

For contained work, a relevant environmental assessment should consider the plausible sequence from escape to survival, reproduction or establishment, spread or persistence, and adverse effects on specified endpoints. Containment should be matched to the species and life stage, including the potential movement of viable material. A biosafety-level label should not substitute for evaluating whether the facility and practices actually prevent the relevant exposure.

Human-pathogen risk groups and containment levels serve different purposes. For gene drive organisms without a primary infectious hazard, NIH should use an additional ecological risk profile rather than force the organism into an infectious-disease classification. Arthropod-specific guidance, including the gene drive containment addendum, should supplement BMBL for insect research. [3,4,8] For vertebrates and other taxa, equivalent species-appropriate expertise should be available.

Suggested language: For gene drive modified organisms, the breadth of assessment shall reflect the specific inheritance mechanism, potential spread and persistence, organism biology, proposed manipulations, and plausible consequences of unintended release. The presence of a gene drive shall not by itself establish a uniform degree of uncertainty or justify the same information requirements for every research stage.

3 Development examples and implications for oversight

Mosquitoes

Malaria mosquitoes provide an advanced contained-research example. Published work includes population suppression in large cages and recent testing of gene-drive-capable mosquitoes against patient-derived malaria parasites in Tanzania. These are distinct milestones; neither should be described as proof of public-health effectiveness following environmental deployment. [9,10] WHO provides a framework for staged testing of genetically modified mosquitoes. [11]

NIH should allow the evidence base from prior studies to inform subsequent assessments where its relevance is justified. An assessment should distinguish pathogen-free insect work from experiments involving infection and should examine the containment implications of the actual mosquito population and location.

Progression to a larger contained study should trigger review of changed exposure opportunities and consequences, rather than automatic repetition of all earlier submissions.

New World screwworm

New World screwworm illustrates why genetic biocontrol must not be equated with gene drive. Genomic research has identified resources relevant to future drive development. More advanced operational innovations include male-only production for sterile insect technique: USDA describes NovoFly as a strain whose released flies undergo irradiation to ensure sterility. These are different biological strategies and evidence bases. [12,13]

NIH should distinguish conventional sterile insects, genetically modified sexing strains, self-limiting systems, and organisms capable of gene drive. The assessment should address the parasitic organism and credible exposure to humans and animals as well as any additional drive-related effects. Prior experience with sterile insect production can inform facility operations where applicable, but should not establish the safety of a fertile drive organism by analogy alone. NIH should provide a clear route for reliance on relevant USDA and EPA findings while retaining review of any remaining laboratory risks not addressed in those findings.

Invasive rodents and other organisms

Mouse research has demonstrated biased inheritance and associated fertility-gene mutations in a laboratory tCRISPR system, alongside modelling of island eradication. The modelled outcome is not evidence that eradication has been demonstrated in the field, and results in house mice should not be generalized to all rodent species. [14]

For invasive-rodent applications, guidance should address the proposed target population, non-target conspecific populations, animal welfare, and the consequences of escape or movement beyond the intended area. The potential conservation benefit of eradication should be described separately from the safety of a particular contained experiment. Other organisms should be assessed using the same principles, with information requirements adapted to their biology rather than copied from the mosquito evidence package.

4 Clarify scope and federal referral thresholds

Section II combines a human-health threshold with exclusions for plants; its interagency reliance provision needs operational detail. Section IV-1 addresses unclassified novel agents. [1] NIH should resolve how these provisions apply to a nonpathogenic gene drive organism, a conservation application, and a synthetic organism without a conventional species classification. Otherwise, both oversight gaps and unnecessary referrals are foreseeable.

A deliberately engineered organism should not require federal review solely because it is novel or absent from BMBL. NIH should define specific referral criteria, including credible potential for serious consequences, inadequately characterized exposure pathways, or uncertainty about whether available controls can adequately reduce risk. These criteria should also capture genuinely consequential synthetic systems that fall outside familiar pathogen categories.

NIH should publish examples distinguishing routine Institutional Biosafety Committee (IBC) review, delegated review, optional scientific consultation, and mandatory federal approval. It should explain the relationship between GDMO-specific requirements and generic low-risk categories. For interagency reliance, NIH should identify which documented determinations can satisfy which requirements, who retains responsibility for

residual laboratory risks, and how conflicting conditions will be resolved. A research grant or an agency relationship alone should not be treated as an applicable biosafety clearance.

If plant gene drives or research with environmental but no identified human-health risk remain outside scope, NIH should identify the rationale, applicable alternative oversight, and route for resolving mixed projects. This comment does not request that laboratory approval confer field-release authorization. NIH should separately clarify the classification of enclosed outdoor facilities and semi-field studies, based on the applicable containment and exposure conditions.

5 Establish an assessment route when no single wild type comparator exists

Sections V-B and V-C rely on parent-organism and sequence-source considerations, including assumptions about function in the original host. [1] These can be useful starting points, but NIH should provide a parallel assessment route for systems for which no single parent is scientifically adequate or available.

Synthetic DNA, synthetic-genome cells, cell-free production systems, and organisms used in biomanufacturing should not be treated as a single hazard class. A synthetic genome may retain substantial biological ancestry: JCVI-syn3.0, for example, was developed through redesign and synthesis of a Mycoplasma-derived genome. [15] Conversely, some prospective systems may combine functions for which no whole-organism comparator adequately describes the hazard. Neither synthetic origin nor a claim of novelty establishes safety or danger by itself.

Where no adequate comparator or history of safe use exists, NIH should accept a weight-of-evidence assessment using relevant chassis information, component functions, functional analogues, system-level properties, and empirical evidence. Comparators may be multiple and endpoint-specific. Assessors should state where analogy is informative and where it fails (transferability uncertainty). A history of safe use should be evaluated against comparable scale, exposure, intended function, and environmental conditions, rather than treated as an unconditional property of a species.

The assessment should address replication, persistence, interaction with other organisms, production of biologically active substances, potential transfer of functional genetic material, detectability, and the effectiveness of proposed controls, as relevant. For biomanufacturing, review should distinguish the production organism, process intermediates, final product, and waste stream. Scale-up, product recovery, and residual viable material can change exposure even when the underlying genetic design is unchanged.

Suggested language: Where no scientifically appropriate parental organism or single comparator exists, assessment shall proceed using a justified combination of functional analogues, component and system-level evidence, and empirical characterization. Lack of a comparator or history of safe use shall be recorded as an evidence limitation whose significance is evaluated for the decision. It shall neither preclude assessment nor establish a presumption of safety. Progression shall depend on sufficient evidence that the proposed activity can be conducted at an acceptable level of residual risk.

NIH should also clarify coverage of acellular nucleic-acid synthesis and synthetic biological products. Scope should turn on reasonably foreseeable biological function and exposure, including relevant downstream use, rather than simply whether a material has yet been introduced into a cell. Sequence provenance, percentage contribution, and computational predictions should inform assessment without substituting for functional context. Initial assumptions should be explicitly revisable.

6 Distinguish mirror biomolecules from self replicating mirror organisms

Mirror proteins and peptides must be distinguished from a self-replicating mirror organism. The 2024 scientific assessment of mirror life identifies serious concerns about possible immune evasion and ecological spread of mirror bacteria, while distinguishing these concerns from research on individual mirror biomolecules. [16]

NIH should assess non-replicating mirror products according to their biological activity, toxicity, persistence, exposure, and disposal requirements. Reversed chirality should not alone trigger the oversight assigned to a self-replicating organism. Conversely, the safety of an isolated mirror protein should not be extrapolated to a mirror cell capable of autonomous propagation.

For research aimed at creating self-replicating mirror organisms, this comment recommends a dedicated federal determination before such creation is authorized. Review should evaluate whether risks can be credibly bounded and whether detection, containment, inactivation, and response assumptions remain valid. Conventional controls should not be accepted solely by analogy to ordinary microorganisms. Where evidence cannot support an acceptable residual risk, the activity should not proceed. NIH should distinguish such work from research that characterizes risks or develops safeguards without enabling organism creation, and should engage relevant federal and international expertise.

7 Anticipate generative optogenetics and programmable biological systems

DARPA's Generative Optogenetics program seeks light-directed synthesis of DNA and RNA within living cells. This is a research objective, not evidence of a mature, unrestricted in-cell synthesis capability. [17] Nevertheless, the prospective ability to change biological outputs through instructions warrants advance clarification of oversight.

NIH should assess both the platform and the range of outputs authorized for a project. IBC submissions should describe the permitted biological functions and the limits of the approved activity sufficiently to determine when changed instructions or generated products require renewed review. Approval of a platform should not be interpreted as approval of every output it might generate. At the same time, minor changes demonstrably within an approved range should not require a complete resubmission.

Future guidance should address traceability of authorized outputs, verification of resulting biological activity, unintended activation or persistence, and changes in scale or exposure. An external control signal should not be assumed to provide complete biological containment. NIH should also coordinate biosafety review with applicable biosecurity and nucleic-acid synthesis screening requirements, recognizing that synthesis within cells may require safeguards beyond those associated with ordering DNA from an external supplier. This is a prospective governance recommendation, not a claim that a particular platform currently bypasses a legal requirement.

Suggested language: For programmable biological platforms, approval shall specify the authorized range of biological functions and the evidence supporting safe conduct. Changes capable of materially altering hazard, exposure, persistence, or control effectiveness shall receive review before implementation. Administrative or technical changes demonstrably within the approved range may be handled through a documented delegated process.

8 Make implementation predictable and proportionate

The proposal introduces approved institutional Assurances and triennial de novo review; it also addresses containment reductions and incident reporting. [1] These processes should strengthen accountability without creating avoidable interruptions in safe research.

NIH should provide transitional recognition of valid existing approvals for a defined period, subject to material safety findings. It should publish completeness criteria and target review timelines, explain when requests for information pause those timelines, and provide an escalation route for unresolved classifications. These procedural commitments should not create approval by default.

For renewals, NIH should permit incorporation of prior assessments and a focused account of changes, incidents, and new evidence. It should clarify whether published containment determinations can support subsequent materially equivalent work and what site-specific confirmation remains necessary. Shared expert resources and *ad hoc* consultants can improve access to ecological, entomological, vertebrate, and synthetic-biology expertise. Scientific independence and conflict management should be preserved without requiring every institution to retain all specialties permanently.

Incident criteria should expressly address environmentally consequential escape, including events without an immediate human infection hazard. Guidance should distinguish a breach within an effective secondary barrier from release beyond containment, while requiring prompt evaluation of both. Public reporting should communicate the event, exposure, consequences, and corrective action accurately, with appropriate protection of confidential information and security-sensitive details. NIH should use aggregated incident learning to improve guidance rather than allow low-consequence events to become misleading proxies for technology-wide risk.

Finally, NIH should maintain updated organism- and technology-specific implementation resources, with examples from mosquito research, screwworm biocontrol, invasive-rodent research, synthetic production systems, mirror biomolecules, and programmable platforms. Periodic consultation with researchers, biosafety professionals, ecological risk assessors, and relevant communities would help those resources evolve with the evidence.

Requested action

NIH is requested to incorporate the proposed methodological language, clarify scope and referral thresholds, and publish practical implementation guidance before the policy takes effect. A coherent framework should enable well-supported contained research to proceed, direct additional scrutiny to uncertainties that matter, and withhold authorization when credible serious risks cannot be adequately controlled. These changes would improve both biosafety and the predictability needed to develop tools for public health, animal health, conservation, and responsible biomanufacturing.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

The proposed policy's focus on the safe conduct of laboratory research is appropriate. NIH should, however, clarify the scope and definition of biohazards to ensure that oversight is **proportionate to the risks of the proposed activity and does not unnecessarily impede research** on emergent use cases *e.g.*, gene drive mosquitoes or their progression toward potential public-health use.

The presence of a genetic modification or gene drive should not, by itself, constitute a finding that an organism presents an unacceptable risk or requires heightened federal oversight. NIH should distinguish eligibility for biosafety assessment from the outcome of that assessment. Research involving gene drive mosquitoes can appropriately undergo institutional review without presuming that every organism, experimental activity, or research stage presents the same hazards.

The definition of biohazards should require a scientifically plausible basis for concern, informed by the organism's characteristics, the proposed activity, and scientifically credible exposure pathways. References to

potential risk should not be interpreted as requiring investigators to eliminate every hypothetical uncertainty. Equally, the absence of a documented adverse effect should not be treated as proof of safety. Information requirements should address uncertainties that could materially change the biosafety decision.

NIH should clarify the treatment of pathogen-free mosquitoes, isolated molecular components, nonviable specimens, and constructs that cannot support gene drive activity under the proposed conditions. These materials and activities should not automatically receive the same oversight as work involving viable organisms capable of transmitting a drive. Clear exclusions, delegated review, and incorporation of existing assessments should be available where justified by the activity's risk. Such determinations should account for whether components could acquire relevant functionality in the proposed experimental context.

The policy should preserve its explicit exclusion of deliberate/ intentional environmental release. Laboratory biosafety approval should neither authorize deployment nor create a duplicative NIH release-approval process. Field testing and public-health use should remain subject to applicable regulatory and federal, state and local requirements (including those on tribal lands). NIH should clarify how enclosed outdoor and semi-field studies are classified and how relevant determinations by other competent authorities may be recognized.

Any inadvertent oversight gaps should be addressed narrowly. In particular, NIH should reconcile the human-health threshold with consideration of environmentally consequential accidental escape from contained research. This can be achieved through targeted guidance on plausible exposure and adverse-effect pathways, rather than a general expansion of NIH oversight to all environmental effects or all uses of genetically modified organisms. Gene drive mosquitoes should not automatically be treated as novel pathogens merely because they are genetically engineered or lack a listing in a pathogen reference document.

We recommend that NIH expressly state: "Inclusion within the scope of this policy does not establish a presumption of high risk. The level of review, information required, and conditions imposed shall be proportionate to the proposed activity and supported by a documented risk assessment. NIH and institutions shall use the least burdensome oversight sufficient to manage identified scientifically plausible harms to mitigate related risks and shall avoid duplicative review."

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).

GeneConvene supports tiered biosafety oversight where the level of review is proportionate to the risks of the proposed activity. Institutional review should ordinarily be sufficient for contained gene drive mosquito research when an appropriately qualified committee can assess the relevant risks and establish effective safeguards. Federal review should be reserved for clearly defined circumstances requiring additional scrutiny or a nationally consistent determination.

NIH should clarify that genetic modification, gene drive capability, novelty, or uncertainty alone does not establish a need for federal escalation. Escalation should identify the specific concern, its significance for the proposed research, and why institutional review is insufficient. The framework should also provide explicit pathways to reduce administrative burden as evidence accumulates, including delegated review, incorporation of previous assessments, and reliance on materially applicable determinations.

For international research, NIH should clarify funding-related responsibilities, recognize equivalent oversight arrangements where appropriate, and support access to shared scientific expertise. Reviews should be

coordinated to avoid duplication while preserving assessment of local facilities and environmental conditions.

Laboratory oversight categories should not become additional authorization requirements for field trials or public-health deployment particularly for international authorities or funders who could treat NIH's laboratory categories as universal risk classifications or prerequisites for release. That would be an interpretation beyond this policy's laboratory purpose. Those decisions should remain with the applicable competent authorities so as not to delay laboratory approval of research and prolong the pathway to use. With these clarifications, tiered oversight could support safe research and responsible progression toward use; without them, ambiguous escalation and overlapping requirements could impose delays disproportionate to the risks.

Issue	Our assessment	Amendment sought
Institutional review as the normal route	Appropriate for contained research where risks can be assessed and managed locally.	Confirm that an adequately supported IBC determination is sufficient unless a defined federal trigger applies.
Federal escalation for novelty or uncertainty	Potentially overbroad if interpreted to capture every new mosquito strain or construct.	Require a documented, decision-relevant concern. Genetic modification, novelty, or absence from a pathogen handbook should not alone trigger escalation.
Reducing oversight as evidence accumulates	Essential for genuine calibration to risk.	Provide routes to streamlined review, reliance on prior determinations, and justified containment reductions.
Repeated and overlapping reviews	Could consume resources without improving the decision.	Permit parallel reviews, reuse of relevant evidence, and clear allocation of responsibilities.
IBC discretion	Valuable, but decentralization alone does not ensure proportionate decisions.	Require reasons for additional conditions and provide access to expert consultation and reconsideration.
International implementation	Potentially burdensome where expertise and administrative resources are limited.	Allow shared expertise and recognition of equivalent institutional arrangements, with site-specific assessment retained.

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

Risk Groups (RGs) remain useful as an initial reference for assessing infectious agents, including parental agents that undergo genetic modification. Their utility is limited, however, for organisms whose principal biosafety concerns involve escape, establishment, inheritance, or ecological effects. NIH should therefore retain RGs as one input where scientifically applicable, rather than use them as a universal classification system for genetically modified organisms.

RGs, Biosafety Levels, and Arthropod Containment Levels should be clearly distinguished. RGs describe agent hazards; BSLs and ACLs describe combinations of safeguards selected for particular activities. These systems are not interchangeable, and their numerical designations do not establish equivalent risk or containment. Genetic modification should prompt assessment of its functional consequences, without an automatic assumption that it increases risk.

For gene drive mosquito research, NIH should explicitly recognize the Arthropod Containment Guidelines and their gene drive addendum as complementary to BMBL. Assessment should integrate any pathogen-related hazards with mosquito biology, the modification, experimental procedures, and the consequences of unintended escape in the local environment. A containment requirement should not be interpreted as assigning the mosquito to a corresponding pathogen Risk Group.

To support consistent international implementation, NIH should provide worked examples, a terminology guide, and a crosswalk explaining how relevant BSL and ACL safeguards satisfy policy requirements. Such a crosswalk should compare specific measures rather than imply automatic equivalence between levels. Guidance should also distinguish laboratory containment decisions from the environmental risk assessment and authorization required for deliberate field testing or deployment.

This approach would preserve appropriate safeguards while reducing unnecessary escalation, duplicative facility requirements, and inconsistent interpretation across research institutions and national authorities.

Concept	**What it describes**	**Appropriate role in mosquito research**
Risk Group — RG	An agent's disease-causing hazards, including severity and transmission characteristics.	Relevant to pathogens used in mosquito infection experiments; insufficient to characterize gene drive spread or ecological effects.
Biosafety Level — BSL	A combination of laboratory practices, equipment, and facility safeguards.	Informs controls for infectious materials and laboratory procedures. It is not an intrinsic property of a mosquito.
Arthropod Containment Level — ACL	Practices and facilities tailored to containing live arthropods and associated hazards.	Directly relevant to insectary operations, escape prevention, and the consequences of escaped mosquitoes.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).

NIH should encourage voluntary adoption through practical support, accessible expertise, and recognition of equivalent biosafety arrangements which would need to be assessed. The final policy should distinguish informal adoption of its principles from formal voluntary participation and clearly explain the obligations associated with each. Institutions outside mandatory coverage should be able to understand whether participation entails an Assurance, reporting requirements, or other administrative commitments before enrolling.

NIH should preserve and update the voluntary-compliance mechanisms in Section IV-D of the existing NIH Guidelines, including access to institutional biosafety review, requests for relevant determinations, and procedures for handling proprietary information. Implementation resources, training, and scientific consultation should be available to institutions regardless of their funding source.

For international gene drive mosquito research, voluntary participation should accommodate national legal frameworks, institutional structures, and access to shared or regional expertise. NIH should recognize scientifically justified equivalent safeguards and existing assessments, while retaining consideration of local facilities and environmental conditions. Documentation requirements should be proportionate to the proposed activity and explicit about handling of proprietary information and confidential materials, public disclosure and incident learning information.

Voluntary participation should support institutional capability and confidence in biosafety practice. It should not become an additional authorization requirement for research, collaboration, field testing, or deployment otherwise governed by competent authorities. NIH should also clarify that participation does not constitute product endorsement or environmental-release approval. These measures would encourage broader uptake while avoiding unnecessary duplication and administrative barriers.

Mechanism	How it would encourage participation
Clearly defined voluntary pathway	Explain eligibility, commitments, benefits, and whether adopting guidance differs from formal participation.
Recognition of equivalent oversight	Allow existing institutional and national arrangements to demonstrate comparable biosafety outcomes without recreating a US administrative structure.
Access to guidance and consultation	Make templates, training, interpretation, and scientific advice available regardless of funding source.
Shared IBC and specialist expertise	Help smaller institutions access entomological, ecological, and containment expertise while retaining local accountability.
Proportionate documentation	Accept relevant existing assessments and limit additional information requests to identified gaps.
Clear information protections	Explain handling of confidential submissions, public disclosure, and incident-learning information before participation.

121. Kathleen Brundage

I am responding: On behalf of myself

Name: Kathleen Brundage

Name of Organization: West Virginia University

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/6/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support expanding oversight beyond recombinant DNA research to encompass the broader range of biohazards encountered in modern biomedical research. The proposed scope aligns well with the oversight currently conducted by our Institutional Biosafety Committee (IBC) and more accurately reflects the evolving landscape of biomedical research.
However, NIH should provide additional clarification regarding key definitions, particularly those pertaining to Gene Drive Modified Organisms (GDMOs). Clear, consistent, and sufficiently specific definitions will help ensure uniform interpretation and implementation of the proposed oversight framework across institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed risk-based oversight structure is appropriate; however, NIH should carefully evaluate the administrative burden associated with expanded transparency, reporting, and documentation requirements. For smaller biosafety programs, maintaining public websites, publishing meeting minutes and incident reports, and managing Biosafety Assurance requirements may require substantial additional resources. At our institution, these responsibilities would largely fall to a biosafety office consisting of only two full-time professionals. These individuals are also responsible for protocol review, laboratory inspections, training, incident response, risk assessments, and research support. Additional administrative requirements could therefore significantly affect the office's capacity to perform these core biosafety functions.
At a minimum, NIH should provide standardized templates, guidance, and implementation tools and should clearly define the responsibilities of the Authorized Organizational Representative (AOR). Oversight requirements should remain proportional to the level of risk and should be designed to minimize unnecessary administrative burden. Institutional resources should remain focused on essential biosafety activities, including laboratory support, risk assessment, training, inspections, and incident response.

3. Continued utility of Risk Groups: Risk Groups should remain an important component of the risk assessment process, while Biosafety Levels should continue to serve as the primary framework for

determining appropriate containment requirements. Biosafety Level assignments more directly reflect the engineering controls, work practices, and facility features needed to mitigate biological risks.
NIH should continue to encourage institutions to consider agent characteristics, genetic modifications, experimental procedures, and potential exposure pathways when determining appropriate containment. Additional guidance on expectations for establishing, maintaining, and managing microorganism inventories would also be beneficial.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH can encourage voluntary adoption of the policy by developing practical implementation resources, model policies, templates, and training materials. Institutions are more likely to adopt recommended practices when expectations are clearly defined, and implementation is straightforward.
At the same time, transparency requirements should be calibrated to minimize the risk that complex scientific or biosafety information could be misinterpreted by individuals without relevant technical expertise. Clear guidance on the presentation and content of publicly available information could help reduce the potential for public misunderstanding or unnecessary concern

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed templates provide a useful framework; however, NIH should provide additional guidance regarding permissible redactions and the protection of sensitive information, including personnel, grant, and clinical research information.
Public disclosure requirements may also have unintended consequences if researchers perceive that reporting incidents or near misses could result in inappropriate or disproportionate public scrutiny. NIH should therefore consider how reporting and transparency requirements can be structured to preserve incentives for timely and candid reporting.
NIH should also reconsider the proposed 24-hour reporting requirement and allow institutions sufficient time to conduct an initial assessment before submitting a report. Providing a reasonable period for preliminary fact-finding would help ensure that reports are accurate and complete.
In addition, incident reporting should be coordinated through institutional biosafety programs rather than individual investigators. Centralized institutional reporting would promote consistency, accuracy, appropriate documentation, and effective institutional oversight.

6. Other feedback relevant to this resource: Additional guidance will be essential to support successful implementation. Areas that would benefit from further clarification include:
• Definitions and oversight expectations for GDMOs
• AOR responsibilities
• Biosafety Officer qualifications and responsibilities
• Microorganism inventory requirements
• Incident reporting procedures and timelines
• Standards and expectations for publicly posted information
Institutions with limited biosafety staffing will also require practical implementation tools and sufficient time to develop compliant processes. For a biosafety like ours, office staffed by only two professionals, requirements associated with website management, public posting, expanded documentation, and additional reporting obligations may necessitate significant operational changes and could divert resources from direct biosafety oversight activities.
Given the scope of the proposed changes, the six-month implementation period may be insufficient for

institutions to establish compliant processes. NIH should consider providing a longer transition period, accompanied by detailed implementation guidance, standardized templates, and practical tools. This approach would facilitate effective and sustainable compliance while minimizing the potential for implementation requirements to reduce institutional capacity for core biosafety oversight.

Description: The draft policy represents a thoughtful and necessary modernization of biosafety oversight and appropriately expands beyond the historical focus on recombinant DNA research. Successful implementation, however, will depend on clear definitions, practical guidance, realistic implementation timelines, and an appropriate balance between transparency and administrative feasibility. NIH should ensure that new requirements strengthen biosafety oversight without diverting limited institutional resources from the primary objective of identifying, assessing, and mitigating biological risks. This consideration is particularly important for institutions whose biosafety programs operate with small staffs like ours and limited administrative support. Requirements should therefore be designed to achieve meaningful improvements in biosafety oversight while remaining proportionate to institutional capacity and practical to implement. Providing clear expectations, standardized implementation resources, and adequate transition time would help institutions meet the objectives of the policy while preserving the capacity needed to perform essential biosafety functions.

122. Arizona State University

I am responding: On behalf of an organization

Name: Zoë Baker

Name of Organization: Arizona State University

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/6/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Arizona State University (ASU) generally supports expanding the scope of the NIH's framework beyond research involving recombinant or synthetic nucleic acid molecules. This expansion is consistent with ASU's existing institutional approach, under which the ASU Institutional Biosafety Committee (IBC) reviews research involving biohazards more broadly. The policy would benefit from greater specificity regarding what research falls within its scope. The draft defines covered research broadly as laboratory biomedical research involving known or potential risks to human health and specified categories of biological materials, while also extending the policy to non-NIH-funded biomedical research conducted at institutions receiving NIH funding. Without additional guidance, these provisions could be interpreted differently across institutions, resulting in potential over-review of low-risk activities and potential gaps in oversight and increased administrative burden at the local and federal levels .

ASU recommends that NIH provide clear examples of both covered and non-covered activities, particularly for primary cells and tissues, blood products, clinical specimens, organoids, microbiome samples, environmental samples, well-characterized cell lines, non-replicating biological materials, and other materials where risk may depend on source and experimental manipulation. NIH should also clarify the treatment of synthetic biology and AI-designed or computationally designed biological agents, including circumstances in which no obvious parent agent exists.

The exclusion of genetically modified plants and plant pathogens that do not cause human disease also warrants additional consideration; although a human-health focused NIH biosafety policy does not need to duplicate USDA or other regulatory frameworks, NIH should clarify how institutions should address genetically modified biological materials that pose ecological or environmental risks.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): ASU generally supports the proposed risk-based structure in which the highest-risk or highest-uncertainty research requires both NIH and IBC approval, most covered research remains under institutional IBC oversight, and specified lower-risk activities may undergo delegated review. This approach appropriately preserves local institutional expertise while reserving federal review for research posing greater risk or uncertainty.

The addition of delegated review is valuable and should help offset some of the burden created by the broader scope of the policy. NIH's proposal currently permits delegated review for activities including RG2 wild-type agents, genetically modified RG1 agents, BSL-1 transgenic organisms, certain low-risk vectors, well-characterized cell lines, and non-Select-Agent toxin proteins. However, additional criteria are necessary to ensure that institutions consistently determine which pathway applies. NIH should provide a decision framework with illustrative examples, clear escalation criteria, and expected review pathways for common research activities. The final guidance should distinguish more clearly among circumstances requiring full IBC review, delegated review, NIH review, or no review.

NIH should also provide expected timelines for federal determinations involving emerging, novel, or zoonotic agents and requests to lower containment. Because research may not begin until required NIH approval is obtained, predictable review timelines will be important to minimizing unnecessary research delays.
The incident provisions should be harmonized across the policy and associated templates. For example, the policy identifies certain animal incidents at BSL-1/ABSL-1 and BSL-2/ABSL-2 as lower-risk events requiring institutional review but not NIH reporting, whereas the draft incident template broadly lists animal bites and scratches among reportable personnel exposures. NIH should resolve such ambiguities and ensure that federal reporting is reserved for incidents of sufficient significance to warrant federal oversight.

3. Continued utility of Risk Groups: ASU supports continued use of Risk Groups (RGs) as an important starting point for biosafety risk assessment. RG classifications provide a useful characterization of the inherent hazards associated with biological agents and facilitate consistent communication across institutions. However, RG classification should not be treated as an automatic determination of the appropriate Biosafety Level (BSL) or Animal Biosafety Level (ABSL). RG and BSL are related but distinct concepts and that appropriate containment depends upon the specific manipulations, genetic modifications, routes of exposure, quantities, procedures, facilities, equipment, personnel expertise, and other experimental conditions involved. ASU recommends retaining both concepts within the final framework: RG as the baseline characterization of inherent agent hazard, followed by an experiment-specific risk assessment that determines appropriate BSL/ABSL containment and additional mitigation measures.

This distinction is particularly important for genetically modified, attenuated, replication-defective, synthetic, or novel biological agents. NIH should provide examples demonstrating how modifications or experimental manipulations may result in containment requirements that are higher or lower than might otherwise be inferred from the parent agent's RG. Guidance for synthetic organisms or constructs with multiple biological sources would also be useful.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): ASU supports the establishment of broadly applicable biosafety principles that can serve as a national model beyond research formally subject to NIH requirements. The draft policy already extends beyond individual NIH-funded projects by applying to biomedical research conducted at institutions receiving NIH funding, irrespective of the specific funding source for the research. NIH should coordinate with other federal agencies and relevant state and local authorities so that institutions are not subject to inconsistent biosafety expectations based solely on

funding source. Broad harmonization of core biosafety principles would be preferable to imposing duplicative or conflicting requirements. NIH should clearly distinguish between mandatory compliance, recommended best practices, and voluntary adoption, so that institutions can understand the legal and administrative implications of each.

For organizations that remain outside the policy's mandatory scope, NIH could encourage adoption through accessible implementation resources, model institutional policies, training materials, risk-assessment tools, and mechanisms through which institutions can voluntarily benchmark their practices against NIH standards.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed incident-reporting and IBC meeting-minutes requirements raise significant concerns regarding proportionality, administrative burden, confidentiality, biosecurity, and the ability of IBCs to conduct candid scientific discussions and safety deliberations.

The draft meeting-minutes template requests detailed project descriptions, experimental manipulations, risk assessments, mitigation strategies, training requirements, occupational health considerations, containment conditions, and other information for each registration. At a large research institution, preparing this degree of detail for public posting could require substantial additional administrative and technical effort. NIH should focus required public minutes on information necessary to demonstrate that the IBC appropriately evaluated risk and fulfilled its oversight responsibilities rather than requiring detailed reconstruction of the underlying protocol.

ASU recommends that NIH provide clearer and more protective rules for sensitive discussions and information. Institutions should be explicitly permitted to enter a closed or executive session when necessary to discuss proprietary, security-sensitive, personnel-related, occupational-health, or other appropriately confidential matters. Public minutes could document that such a discussion occurred, its general purpose, and any resulting IBC action without disclosing protected details.

The proposed redaction standards should be revised. The templates acknowledge that proprietary, private, and security-sensitive information may be redacted, but also state that information available elsewhere—including biological agents used in research, including Select Agents—generally may not be redacted. NIH should permit institutions to evaluate information in context: the aggregation of individually public facts may create meaningful security, proprietary, or research-integrity concerns.

Similarly, incident reporting should be risk-proportionate. The policy should clearly distinguish incidents requiring NIH reporting and public posting from lower-risk events managed locally. NIH should consider a streamlined institutional record for low-risk incidents rather than requiring the same reporting structure used for more consequential events. Public reporting should provide sufficient context to reduce the likelihood that routine or appropriately managed incidents are misleadingly interpreted as evidence of unsafe research practices.

Transparency requirements should be designed so that they do not inadvertently discourage timely incident reporting or candid discussion by investigators and IBC members. A strong safety culture

depends on open reporting of errors, near misses, and concerns without creating unnecessary reputational disincentives.

6. Other feedback relevant to this resource: Substantial implementation guidance will be essential before the new policy becomes effective. Consistent implementation will depend upon institutions having detailed, practical resources.

ASU recommends that NIH prioritize guidance addressing:
- Decision trees and examples distinguishing covered, non-covered, and potentially exempt low-risk research
- Criteria and examples for full IBC review, delegated review, NIH review, and activities requiring no review
- Treatment of primary cells and tissues, clinical specimens, blood products, organoids, microbiome and environmental samples, well-characterized cell lines, and non-replicating biological materials
- Synthetic biology, AI-designed biological systems, and novel agents for which conventional RG classification may be difficult
- Ecological and environmental risks and the relationship of the NIH policy to other federal oversight frameworks
- Experiment-specific use of RG classifications and BSL/ABSL determinations
- Thresholds and examples for NIH-reportable versus institutionally managed incidents
- Appropriate redaction standards, treatment of sensitive information, and use of closed/executive IBC sessions
- Standardized but proportionate approaches to meeting minutes and incident reporting
- Coordination among IBCs, IRBs, IACUCs, occupational health programs, environmental health and safety programs, and other institutional oversight bodies where responsibilities overlap.

Given the expansion in scope, development of new institutional procedures and assurances, changes to electronic systems, training needs, and increased administrative responsibilities, ASU encourages NIH to evaluate whether a longer or phased implementation period would better support consistent and effective compliance.

123. Ericka Pearce

I am responding: On behalf of myself

Name: Ericka Pearce

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/6/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Scope of Genetically Modified Organisms

I support NIH's goal of ensuring appropriate oversight of emerging biotechnology and genetically modified organisms. However, the proposed scope provision covering "cells, viruses, or organisms, other than plants, that have been genetically modified" may unintentionally expand IBC oversight to a broad range of routine, low-risk research activities.

As written, the definition of genetic modification includes nucleic acid molecules that "can be transcribed or translated," potentially encompassing common molecular biology tools and models such as expression vectors, reporter constructs, commercially available modified cell lines, transgenic animals, and CRISPR-edited cells with well-characterized risk profiles.

Having reviewed countless protocols over the course of my career, my concern is not whether genetically modified materials warrant oversight, but whether oversight should be triggered by the presence of a genetic modification alone rather than by the risks associated with that modification.

Operational Impact

A broad interpretation could substantially increase the number of protocols requiring review, lengthen review timelines, and divert limited biosafety resources away from higher-risk activities. The timing of this proposal further compounds these challenges, as institutions are simultaneously implementing other significant federal oversight initiatives related to biosecurity and high-consequence life sciences research.

Recommendation

NIH should clarify whether oversight is intended to be triggered by the presence of a genetic

modification or by the biosafety and biosecurity risks associated with that modification. I encourage NIH to adopt a risk-based approach and consider exclusions for common, low-risk molecular biology tools, established research models, and commercially available reagents. Oversight should be commensurate with risk rather than modification status alone.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

124. Perla J. Rodriguez

I am responding: On behalf of myself

Name: Perla J. Rodriguez

Name of Organization:

Type of Organization: Non-Profit Research Organization

Role: Other

Role - Other: Senior Safety Analyst - support and manage our IBC

Date Submitted: 10/7/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Translational Medicine

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am submitting these comments in my individual capacity. The opinions expressed are my own and do not represent the views of my employer.
The proposed expansion of oversight to all biomedical research involving biohazards is understandable; however, several core definitions remain insufficiently specific to support consistent institutional implementation.
Additional clarification is needed regarding:
• The definition of "biomedical research."
• The meaning of "potential risk to human health."
• The intended scope of "biohazards."
• Activities that are regulated versus operational or clinical in nature.
Specific research activities that would benefit from clarification include:
• Human-derived materials with unknown infectious potential.
• Clinical specimens collected for research purposes.
• Environmental and wastewater surveillance samples.
• Microbiome research.
• Biobanking activities.
• Attenuated or replication-defective systems.
• Research involving non-pathogenic genetically modified organisms.
• Emerging synthetic biology applications.
The broad definitions may result in considerable variability in how institutions determine what requires IBC review. NIH should consider developing a scope determination guide or decision tree containing examples of included and excluded activities, similar to how the current NIH Guidelines use experiment categories to establish oversight expectations.
Additionally, while the policy expands oversight substantially, there remain potential gaps related to research involving emerging biological technologies, AI-enabled biological design, and novel biological

systems that may not fit neatly within traditional risk classifications. Additional guidance on these areas would be beneficial.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed tiered oversight structure is conceptually appropriate and aligns with the principle that oversight should be commensurate with risk. However, several aspects of the federal-local oversight relationship require clarification.

The draft significantly expands IBC responsibilities while providing limited guidance regarding:

- Institutional authority versus IBC authority.
- Delegated review processes.
- Administrative review mechanisms.
- Accountability for risk determinations.
- Roles and responsibilities within centralized or externally administered IBC models.
- Processes for resolving disagreements regarding risk assessments.

The policy would benefit from a clearly defined governance framework that describes which decisions belong at the institutional level versus the federal level and how local discretion should be exercised.

The draft also introduces a number of circumstances requiring NIH consultation or approval. Additional guidance should be provided regarding expected timelines for NIH review and how institutions should manage research activities pending federal determinations.

For multisite research, NIH should consider whether centralized or single-IBC models may be appropriate for certain types of studies, similar to the single-IRB approach used for human subjects research. Such models could reduce duplicative review while maintaining appropriate oversight.

3. Continued utility of Risk Groups: Risk Groups continue to provide value as a foundational risk assessment tool; however, they should not be used as the sole determinant of containment requirements.

The current NIH Guidelines appropriately recognize that risk assessment involves multiple factors in addition to RG classification. These factors include:

- Host range.
- Route of exposure.
- Experimental manipulations.
- Availability of prophylaxis or treatment.
- Animal model considerations.
- Genetic modifications.
- Environmental risks.

The proposed policy emphasizes independent risk assessment by institutions and IBCs, yet does not provide a standardized methodology for performing those assessments.

NIH should consider developing:

- Standardized risk assessment templates.
- Examples of completed risk assessments.
- Decision trees linking RGs, BSLs, and experimental factors.
- Guidance regarding acceptable documentation standards.
- Case studies involving genetically modified organisms and novel agents.

RGs remain useful as a starting point; however, BSL assignments and containment decisions should continue to be driven by a holistic risk assessment framework rather than RG classification alone.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Encouraging adoption beyond NIH-funded institutions is an important objective. Voluntary compliance is most likely to occur when the policy is practical, clearly written, and supported by implementation resources.

NIH could encourage broader adoption by providing:

- Model institutional policies.
- Risk assessment templates.
- Training materials.
- Frequently asked questions.
- Example workflows.
- Sample committee procedures.
- Publicly available educational resources.

The policy should be viewed as a framework that institutions can realistically implement rather than solely a regulatory requirement.

The success of voluntary compliance will also depend on maintaining reasonable administrative burden. Institutions are more likely to adopt the framework if requirements are clearly risk-based, scalable, and supported by practical tools.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed emphasis on transparency is commendable and likely to strengthen public trust in research oversight. However, several aspects of the reporting and public posting requirements would benefit from clarification.

Incident Reporting:

Several reporting triggers remain open to interpretation, including:

- "Potential laboratory-acquired infection."
- "Potential community risk."
- "Potential release."
- "Significant risk to human health."
- "Agent-specific treatment."

More objective reporting thresholds would help ensure consistency among institutions and reduce the potential for both under-reporting and over-reporting.

NIH should consider publishing:

- Reportability decision trees.
- Case studies.
- Frequently encountered examples.
- Reporting threshold guidance.

In addition, expanded reporting and public disclosure requirements should be carefully balanced against maintaining a strong institutional reporting culture. Effective biosafety programs depend on the willingness of personnel to report incidents, near misses, and lessons learned. Requirements should be structured to encourage transparency and continuous improvement rather than create perceived disincentives to reporting.

Meeting Minutes

Additional guidance is needed regarding:

- Appropriate levels of detail.
- Protection of proprietary information.

• Protection of intellectual property.
• Protection of unpublished scientific findings.
• Patient privacy considerations.
• Information that could create biosecurity concerns.
Standardized redaction guidance and sample meeting minutes would help institutions implement these requirements consistently.

6. Other feedback relevant to this resource: The following resources would be particularly valuable:
Transition Resources
• Formal crosswalk between the current NIH Guidelines and the proposed oversight structure.
• Grandfathering guidance for active protocols.
• FAQs regarding implementation.
• Examples of compliance expectations during transition.
Governance Resources
• Guidance on IBC authority and delegation.
• Model governance frameworks.
• Examples of centralized and shared IBC models.
Clinical Research Resources
Additional guidance is needed regarding:
• Gene therapy studies.
• Cellular therapy studies.
• Shedding assessments.
• Clinical administration of biohazardous products.
• Multisite clinical studies.
• Coordination among IBCs, IRBs, clinical research personnel, and study teams.
The policy should also address how biosafety expectations apply in clinical environments that do not operate under traditional BSL frameworks, such as:
• Outpatient infusion centers.
• Inpatient units.
• Pharmacies.
• Clinical specimen processing areas.
Coordination with Other Oversight Programs
Additional guidance should clarify how responsibilities should be coordinated among:
• IBCs.
• IRBs.
• IACUCs.
• Occupational Health Programs.
• Environmental Health and Safety Offices.
• Institutional incident management programs.
Without clear delineation of responsibilities, there is potential for duplicative review and administrative burden without corresponding improvements in safety.
Institutional Assurance Resources
The proposed Institutional Biosafety Assurance program represents a substantial new obligation.
Additional guidance should clarify:
• NIH review timelines.

• Approval and renewal processes.
• Required updates between renewal cycles.
• Implications of delayed approvals.

Implementation Timeline

Finally, many institutions will need significant time to update policies, train personnel, revise systems, establish assurance processes, and adjust committee operations.

Given the breadth of the proposed changes, NIH should consider whether a six-month implementation period is sufficient and evaluate the benefits of a phased implementation approach supported by transition guidance and outreach activities.

Conclusion

Overall, I support NIH's effort to modernize biosafety oversight and establish a comprehensive framework that reflects contemporary biomedical research. The areas most in need of additional clarification are: (1) scope and definitions; (2) governance and authority; (3) standardized risk assessment expectations; (4) clinical research oversight; (5) incident reporting and transparency requirements; and (6) implementation resources and transition planning. Addressing these issues prior to finalization will improve consistency, reduce institutional variability, and enhance successful adoption of the policy across the research community.

125. Cleveland Clinic

I am responding: On behalf of an organization

Name: blair barnhart-hinkle

Name of Organization: Cleveland Clinic

Type of Organization: Healthcare Institution

Role: Organizational Official

Date Submitted: 10/7/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cleveland Clinic

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Draft NIH Biosafety Policy for Research Involving Biohazards demonstrates the NIH's firm commitment to ensuring that all work performed at NIH funded institutions is done safely. Updated guidance regarding transparency helps to assure surrounding communities that scientific breakthroughs are not coming at the expense of public interest. We appreciate this opportunity to comment and offer feedback that we hope will further both the ideals presented in these documents as well as those of the NIH as an institution.

The draft policy substantially expands the scope of activities requiring Institutional Biosafety Committee (IBC) oversight beyond recombinant or synthetic nucleic acid molecule research to include biomedical research involving known or potential biohazards. This would impose a significant regulatory and administrative burden on both investigators and institutional biosafety programs by requiring registration of routine, low-risk research materials and activities. As currently framed, the policy could require principal investigators to individually register every gene target, well-characterized cell line, plasmid, transgenic organism cross, and similar research material, even when the work is conducted at Biosafety Level 1 (BSL-1) or Animal Biosafety Level 1 (ABSL-1). Requiring IBCs and biosafety offices to triage a much larger amount of low-risk research could lengthen review timelines and consume committee and administrative resources. This could dilute attention from higher-risk research, incident follow-up, facility-specific biosafety concerns, and substantive biosafety program oversight.

NIH should identify categories of low-risk research, or protocol amendments, that may be excluded from formal oversight – or at most acknowledged or registered at the institutional level – to avoid unnecessarily expanding oversight. Although the draft policy contemplates delegated review, it does not clearly specify the level of review required for those determinations. If review and approval is required for routine low-risk activities, such as transient transfections, transgenic organisms without hazardous gene expression etc., or Risk Group 1 modifications that do not present a credible biosafety concern, oversight should not go beyond knowing that these general categories of work are occurring in a laboratory and ensuring that appropriate risk-based containment, facilities, training, and safety practices

are in place. It should not require detailed activity-by-activity review. Activity- by-activity review, whether it is delegated or full committee review, should be reserved for higher-risk agents, hazardous modifications, or work involving uncertainty where substantive review is necessary to ensure safety. Furthermore, additional information would be required to identify the scope of review needed for clinical studies and transgenic animals. Ideally, transgenic animals not considered Gene Drive Modified Organisms (GDMOs) or modified only to express low-risk transgenes should be exempt from IBC review due to the low risk of the associated modification to the handler and the environment

Below are some examples of minimal biosafety risk that should be excluded:
1. Use of research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes in tissue culture (e.g. simple gene overexpression or knock down in tissue culture in which infectious agents, toxins, or other hazardous gene products).
2. Research with well-characterized cell lines used in combination with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low risk transgenes in tissue culture at BSL1 or BSL2, where infectious agents, toxins or other hazardous gene products are not anticipated to be present or produced.
3. Research conducted with transgenic organisms at BSL1/ABSL1 containment.
4. Research with K-12 E. coli to perform DNA amplification and purification at BSL1.
5. Research with non-K12 E.coli to perform protein expression and purification at BSL1, where toxins are not produced.
6. Research with the expression of non-toxic B subunit of toxins only, in which the active, toxic component (A subunit) is not present.

If the agency does not exclude these activities, we recommend a requirement to ensure that review of general categories of work and appropriate containment and safety measures are in place.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The draft policy appropriately identifies categories of research that require both NIH and IBC approval prior to initiation. This approach is particularly valuable for emerging, novel, or otherwise unclassified agents, where centralized review can promote consistency in risk assessment and containment recommendations across institutions. We support this aspect of the framework as a means of improving standardization and reducing variability in oversight. Nonetheless, concerns remain regarding the time required for NIH assessment and approval, particularly when research involving emerging or novel pathogens may be urgently needed to inform public health responses, characterize newly identified agents, or to develop diagnostics, therapeutics, and vaccines. Consideration should be given to establishing defined review timelines or expedited review pathways for time-sensitive research while maintaining appropriate biosafety oversight.

While the scope of the proposed policy expands beyond recombinant DNA research to encompass a broader range of biohazards, the majority of research activities would continue to be reviewed at the local level, which we believe is appropriate and allows institutions to apply site-specific expertise, facilities knowledge, and operational considerations to the oversight process. While centralized NIH review is available for research where there is no standard, concerns remain regarding the continued local review of activities that present minimal biosafety risk. Requiring protocol-specific review of routine, low-risk research, with a policy that significantly expands the scope of review, may impose

substantial administrative burden without a commensurate biosafety benefit. Clear exclusion criteria and expanded use category-based review for well-defined low-risk activities would allow institutional resources to be focused on research with meaningful biosafety implications.

3. Continued utility of Risk Groups: An initial classification of a biological agent is a useful starting point for biological risk assessment because they categorize agents based on known characteristics. However, an agent's risk can change substantially when genetic modifications are introduced, or they are used in high concentrations. Biosafety Levels (BSLs), when assigned through a comprehensive risk assessment, are often more useful for determining the actual risk of the final material and the containment needed for the specific work being performed.

This distinction is already evident for many emerging vector-borne viruses. These viruses are classified as RG2 but are routinely handled at BSL-3 because of factors such as aerosol transmission potential, limited medical countermeasures, uncertainty about pathogenicity, or the procedures being performed. Even without genetic modification, containment requirements may exceed what researchers expect based solely on RG classification. While experienced biosafety professionals generally understand this distinction, it can be confusing for junior biosafety professionals, investigators, and new researchers. The terminology can also be misleading because an assigned "Risk Group" does not necessarily reflect the actual "risk" to the use of a biological agent or translate directly to the appropriate containment level.

Having an initial reference point for evaluating a pathogen before considering additional factors such as agent characteristics, proposed modifications, procedures, and containment practices is beneficial. To reduce confusion, NIH could consider terminology that more clearly distinguishes an agent's baseline classification from the final risk-based containment determination of BSL. Examples might include "Initial Agent Hazard Group," or "Starting Risk Classification" in place of "Risk Group." This type of nomenclature would reinforce that this initial classification informs the assessment of what biosafety level to work at but does not independently determine the appropriate biosafety level.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): For entities not receiving federal funding, consideration should be given to requiring compliance with NIH biosafety standards, or equivalent recombinant DNA oversight requirements, as a condition for future federal funding, regulatory review, or advancement of products through later stages of development. For example, companies conducting research without federal funds could be expected to demonstrate adherence to NIH recombinant DNA and biosafety requirements, or equivalent standards, when seeking FDA approval or advancing products through later stages of development. This would promote consistent biosafety practices across the research and product development pipeline.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The updated meeting minutes template and additional clarifications regarding the public meeting minutes will be helpful in drafting the document, but as written, the guidance suggests the draft template is the required format and implies institutions are asked to list every organism and manipulation. It is not unusual for the IBC to review multiple protocols a month that include over 100 individual bacteria, viruses, and cell lines. While the Committee reviews each item, and they are documented in the IBC protocol, repeating that information in the minutes would expand them to a size where it would be offering no clarity for local communities.

While the meeting minutes should mention all items that fall under the policy, being able to group certain items or lower risk agents under general categories or allowing institutions to adapt the template would be appreciated. For example, if a lab is overexpressing oncogenes in 30 Risk Group (RG) 2 human cell lines with 10 different viral vectors; instead of listing all 40 items individually, this could be accomplished with, “Oncogenes may be overexpressed in human cell lines using replication defective viral lentiviral vectors. Experiments are performed at BSL-2.”

Although incidents are now required to be made publicly accessible on institutional websites, we recommend that the Annual Incident Summary Report should preserve institutional anonymity where appropriate to avoid unintentionally identifying, targeting, or misrepresenting a single institution. This is particularly important when the annual report may not include sufficient detail regarding the circumstances of the incident, its context, corrective actions, and final resolution.

6. Other feedback relevant to this resource: While the draft policy will be an enormous step forward in safety and transparency for NIH funded research, we urge NIH to consider allowing a timeframe (4-6 months) between release of final policy and start of implementation for institutions to devise and implement new training and documents. Ideally policy implementation would also occur over an extended period (6-8 months) as well to ensure all applicable research is accurately identified, reviewed, and approved.

Additionally, we would appreciate clarification on the following items:
• GDMOs: Examples of currently used applicable techniques would be appreciated, along with a definition of what is meant by “organism”. Furthermore, does this reference sexually reproducing multicellular organisms only or are lower-level organisms included as well (bacteria, viruses, tissue culture, etc.).
• Well Characterized Cell Lines: Specific criteria would be appreciated. We propose well-characterized cell lines would include that the cell line had no known infection at time of acquisition, has not been exposed to an infectious agent after acquisition, are either non-recombinant modified or have only been modified to express low-risk transgenes, such as GFP, and are screened for common bloodborne pathogens. We recommend that this work be excluded from routine review or, at most, require a brief description of the general category of research. This would allow verification that appropriate biosafety practices, containment measures, and institutional safety protocols are in place, rather than necessitating an itemized review of individual cell lines meeting the above criteria. This approach would ensure that oversight remains consistent with the scope and intent of the policy, focusing on safety and compliance without creating unnecessary administrative burdens for research activities that present minimal biohazard risk.
• Low-risk Transgenes: Criteria for what would be considered a low-risk transgene would be appreciated. We propose that low-risk transgenes should include fluorescent tags and antibodies, transgenes not considered oncogenes or tumor suppressor genes, transgenes produced by non-pathogenic organisms, and transgenes that have no known causative role in disease. Additional guidance on the distinction between low-risk and hazardous gene products would improve consistency across institutions and help focus IBC review on research with substantive biosafety risks rather than routine tissue culture applications. We recommend that this work be excluded from routine review or, at most, require a brief description of the general category of research. This would allow verification that appropriate biosafety

practices, containment measures, and institutional safety protocols are in place, rather than necessitating an itemized review of individual genes meeting the above criteria. This approach would ensure that oversight remains consistent with the scope and intent of the policy, focusing on safety and compliance without creating unnecessary administrative burdens for research activities that present minimal biohazard risk.

• Section IV-2: As we understand the categories for IBC regulated clinical trials, this would exclude work with some mRNA therapies from IBC review, as they are generally non-integrating and don't shed or replicate. We urge NIH to clarify whether this is the correct interpretation, or if any therapy that results from expression of an exogenous protein (i.e. mRNA that results in expression of a viral protein for a vaccine) is under IBC purview.

• DNA segments Risk Group 3 and 4 agents: We suggest NIH clarify whether institutions must petition the NIH to determine the appropriate biocontainment level for experiments in which DNA from Risk Group 3 or 4 agents is transferred into nonpathogenic prokaryotes or lower eukaryotes, in which an infectious agent is not anticipated to be produced (e.g. single viral gene expression) If the IBC or delegate identifies the risk to be low, we recommend approval at the Institutional level.

• Room Amendments: We suggest NIH clarify the process for approving new locations of work for previously approved procedures. We recommend that approval of room changes be explicitly included in Section IV-3 (Delegation), enabling each institution to determine whether such approvals may be handled by the Biological Safety Officer (BSO), a designated subgroup of IBC members, or referred to the full Institutional Biosafety Committee for review. This flexibility would allow institutions to align review pathways with the complexity of their facilities and the nature of the proposed changes, ensuring that modifications warranting comprehensive evaluation are brought before the full committee, while routine or lower-risk changes can be managed quickly and efficiently through delegated review.

• Delegated Review Requirements: We urge the NIH to clarify whether institutions may establish, at their discretion, criteria for determining which amendments qualify as eligible for delegated review versus those requiring full IBC review.

We appreciate NIH's efforts to modernize biosafety oversight and develop a framework that is risk-based, scalable, and adaptable to emerging technologies. Given our institution's extensive experience in biosafety, recombinant and synthetic nucleic acid research oversight, high-containment research, animal research, and implementation of institutional biosafety programs, we would welcome the opportunity to participate in future working groups, advisory committees, stakeholder discussions, or pilot implementation efforts related to this policy. We would be happy to serve as a subject matter resource to NIH as the policy and associated guidance documents are refined to ensure they are both scientifically rigorous and practical to implement across diverse research environments.

Date Submitted: 10/7/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer and neuroscience

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As written, the scope would cover all biomedical research using animals since every animal possesses wide-type biological agents that can cause disease in humans. In section IIIB, the draft policy states that exposures due to adventitious agents, such as from an animal bite, not deliberately involved in the research are excluded from reporting. Please clarify if the policy only covers research in which agents are deliberately administered to humans or animal.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The language on the incident report is very vague, and appears to cover every scenario in which an individual in injured in an animal facility. For example "Any incident at BSL-1/ ABSL-1 that does not involved agent specific medical treatment when first aid is administered" implies that any slip, fall or accident that occurs in the vivarium needs to be reported to the IBC. Since the stated purpose is to reduce "red tape" for low risk research, both the scope of what is covered by the policy needs to be clarified.

6. Other feedback relevant to this resource: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Will the citations/sections previously built into the NIH Guidelines be incorporated into the new policy? Or is this now a more subjective risk assessment process?

Why are plants specifically omitted? Are there no concerns for ecological (e.g., crop) impact?

For research that must be reviewed by the IBC, must the review take place at a convened meeting with a quorum of members?

It would be preferable if the new NIH policy only applied to federally funded research (similar to NIH oversight of animal research). The involvement of an assurance (like for animal research) should also be limited to federally-funded work (unless an institution decides to increase the scope).

Does the new policy apply to biosafety in instruction (e.g., undergraduate coursework) or just in "research"?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): virology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Draft NIH Biosafety Policy for Research Involving Biohazards is not ready for implementation. Replacing a framework developed and refined over decades requires a policy that is at least as operationally coherent, technically complete, and administratively workable as the framework it supersedes. This draft is not. It expands institutional jurisdiction dramatically—including to non-NIH-funded research at any institution receiving NIH funds—while replacing much of the current Guidelines' specificity with broad definitions, incomplete categories, undefined terms, and requirements whose practical consequences have not been adequately resolved.

The current NIH Guidelines are often overly detailed, use confusing terminology, and contain provisions that can be difficult to reconcile. Those shortcomings warrant modernization. The proposed replacement, however, overcorrects: it is simultaneously too sparse to guide consistent decisions and too broad to permit proportionate implementation. Core requirements are deferred to future supplemental materials even though institutions would have only six months to bring new and ongoing research into compliance. A complete overhaul should not be finalized until the operative guidance, templates, examples, decision rules, and implementation resources are available for public review as an integrated package.

"Gold-standard" language
The repeated assertion that NIH will ensure "gold-standard science" under "gold-standard biosafety conditions" should be stricken. The phrase is tacky, self-congratulatory, and reads as propaganda rather than technical policy. "Gold standard" has no defined operational meaning here and adds nothing to the enforceable requirements. A federal biosafety policy should state measurable objectives—safe, proportionate, evidence-based, consistent, and adaptable oversight—rather than rely on promotional slogans.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The draft greatly expands the number and variety of activities requiring review while simultaneously increasing IBC documentation, monitoring, reporting, posting, and assurance obligations. It extends the policy to wild-

type RG2 agents, genetically modified cells, primary cells that may contain adventitious agents, toxins, prions, and covered non-NIH-funded work at NIH-funded institutions. It also requires de novo review at least every three years, periodic compliance review, reporting of delegated approvals at the next meeting, NIH petitions in uncertain cases, and use of mandatory templates.

This is an unfunded mandate of substantial scale. NIH has not demonstrated that institutional IBCs—or NIH itself—have the staffing, subject-matter breadth, administrative support, and review capacity necessary to implement it without delaying research or diverting attention from higher-risk oversight. Requirements that consume committee attention indiscriminately can reduce safety by obscuring the relatively small subset of activities that warrants intensive scrutiny.

NIH should conduct and publish an administrative-burden analysis before finalization. The final policy should authorize proportionate mechanisms such as documented exemptions, notification-only categories, staff or biosafety officer review, delegated review, approved institutional risk matrices, umbrella protocols for recurring low-risk work, and clear amendment thresholds. Delegated review should not require reproducing every low-risk approval in public-facing committee records; a concise docket would be more proportionate.

The draft properly recognizes that both the agent and the proposed manipulations matter. The BMBL likewise treats protocol-driven risk assessment as its core principle and explicitly cautions that no single document can enumerate every combination of hazards and mitigations. The problem is not experiment-specific risk assessment itself; it is the draft's failure to establish a workable division of labor and appropriate level of granularity. The PI should retain primary responsibility for experiment-level risk assessment, selection of practices and containment within the boundaries of an approved protocol, personnel training, and day-to-day implementation. The IBC should independently review the PI's assessment, approve agents and defined classes of manipulations, set containment floors and conditions, and examine material changes or unusually hazardous experiments. It should not be necessary for the full IBC to separately reconstruct and document the risk assessment for every assay, minor procedural variant, or routine experiment conducted by a large laboratory. The current Guidelines already assign the PI the initial containment determination and require independent IBC assessment; the replacement should preserve and clarify that allocation rather than blur operational ownership.

The policy should therefore distinguish among:
• Project-level approval: agents, constructs, broad activity classes, facilities, personnel qualifications, and containment boundaries.
• PI-controlled experiment-level implementation: specific procedures that remain within the approved risk envelope.
• IBC re-review triggers: changes reasonably likely to alter hazard, exposure probability, consequence, containment, occupational-health needs, environmental risk, or the validity of previously relied-upon mitigation.
• NIH review: genuinely novel or high-consequence questions that cannot be resolved using established agents, parent-agent classifications, published precedent, or defined federal decision rules.

The draft requires re-review of changes that have a "potential impact on the original biosafety

assessment," but that phrase is too indeterminate to support consistent compliance. Almost any procedural change could be said to have some potential impact. NIH should define materiality and provide examples of changes that do and do not require prospective re-review. Re-review should be limited to changes reasonably likely to alter hazard, exposure probability, consequence, containment, occupational-health needs, environmental risk, or the validity of previously relied-upon mitigation. Changes that remain within previously approved containment, agent, construct, procedure, scale, and exposure parameters should be handled through institutional amendment pathways without mandatory full IBC re-review.

3. Continued utility of Risk Groups: The policy's stated scope lacks internal coherence. It invokes risk to humans and the environment, defines "biological agent" as an organism that causes human disease, excludes plants, and addresses zoonotic agents, animal prions, gene-drive organisms, and environmental risk without presenting a coherent One Health framework. NIH should state expressly how the policy interfaces with USDA APHIS, the Federal Select Agent Program, EPA, FDA, and other federal authorities for plant pathogens, animal-only pathogens, zoonotic agents, agricultural agents, and agents with uncertain host range. The clause allowing work under another federal agency's oversight does not explain which regime controls when jurisdiction overlaps, when another agency's review is narrower, or when an animal or plant pathogen is being developed as a vector, vaccine platform, or oncolytic agent for human use. Risk should be based on the properties and intended use of the material, not solely on whether the parental organism is conventionally labeled a human, animal, or plant pathogen.

The definition of "biohazard" for scope purposes depends on "known or potential risk to human health," but that phrase is undefined. Without a threshold of plausibility and consequence, the policy could sweep in an enormous range of materials for which any human-health nexus is merely theoretical. NIH should define the required nexus to human health and distinguish credible biological risk from speculative possibility.

The definition of "emerging agent or organism" is scientifically nonstandard and too narrow. Emerging infections commonly include diseases that newly appear in a population or are increasing in incidence or geographic range. Zika virus illustrates the problem: it was first isolated in 1947 but caused its first recognized epidemic in 2007 and later expanded dramatically in geographic range. The definition should encompass newly recognized agents, known agents exhibiting materially changed epidemiology or phenotype, and known agents entering new populations or ranges.

The definition of "novel agent or organism" is also insufficiently defined. As written, it could be read to encompass ordinary engineered mutants without distinguishing them from substantially redesigned or genuinely unprecedented agents. NIH should specify whether "novel" requires the absence of an established parent-agent risk classification, a materially new phenotype, a substantial genomic redesign, or uncertainty that cannot be resolved through ordinary institutional risk assessment.
The petition requirements are also disproportionate and appear skewed toward attenuation or loss-of-function examples. Many modifications are neutral, incompletely characterized, or intended to add a laboratory function such as reporter expression. NIH should request only information material to the containment decision and should offer abbreviated petitions based on parent-agent precedent, construct class, and validated institutional risk assessment.

Modern virology and vectors

The policy does not provide an operational framework adequate for modern virology. It should distinguish, with examples and decision criteria, among genetically modified replication-competent viruses, replication-defective viruses, single-cycle viruses, viral vectors, pseudotyped particles, virus-like particles, helper-dependent systems, producer cells, packaging systems, trans-complementable replicons, and infectious clones. It should also address the probability and consequences of recombination, complementation, mobilization, replication-competent revertants, altered tropism, and rescue in trans. The current NIH Guidelines expressly address defective viruses in helper systems and the possibility of generating replication-competent virus; the replacement policy should not discard that operational clarity. Terms such as “replication-incompetent,” “non-integrating,” “reporter,” “low-risk transgene,” and “well-characterized cell line” require definitions or decision criteria. A vector can be replication-incompetent yet still present meaningful hazards related to transduction, insertion, mobilization, expression product, pseudotype, or accidental complementation.

Clinical research

The category for clinical administration should be clarified with worked examples. “Capable of shedding, replicating, or integrating” is not sufficiently precise and may be interpreted inconsistently across self-amplifying RNA, genetically modified cells, integrating-vector products, non-replicating viral vectors, and oncolytic viruses. The policy should classify CAR-T and other genetically modified cell products, self-amplifying RNA, AAV-mediated gene delivery, non-replicating viral vaccines and vectors, oncolytic viruses, bacteriophage products, microbiome products, and products for which only residual vector components may be detectable. Risk categories should focus on occupational and environmental biosafety questions that are within IBC expertise: preparation and administration, sharps and aerosol risks, replication competence, shedding, contacts, waste, spill response, and environmental release. The policy should also explain the endpoint of IBC oversight for long-lived or integrating products rather than presuming that the last administered dose is generally an adequate endpoint.

Wild-type RG2 agents

The draft appropriately requires review and approval for research involving wild-type RG2 biological agents, but it does not adequately explain why all such work should require prospective approval rather than a mixture of notification, standing institutional controls, delegated review, and full review based on manipulation and context. The final policy should make clear that antimicrobial-resistance phenotype, transmissibility, available countermeasures, route of exposure, concentration, scale, and procedure hazards can elevate a wild-type RG2 project. Conversely, routine work with well-characterized RG2 organisms under standard research conditions should not consume the same review resources as work involving enhanced resistance, aerosol generation, large scale, animal transmission, or altered host range.

Influenza provisions

The continued exceptional treatment of influenza should either be justified by a generalizable risk

principle or replaced with phenotype- and consequence-based rules applicable across virus families. A segment-counting rule is an inadequate surrogate for risk because a minority of segments can materially alter receptor use, replication, host range, antigenicity, drug susceptibility, or transmission. At a minimum, the policy should require the higher applicable starting containment when any segment derives from a higher-risk parent, followed by a documented risk assessment that considers the identity and function of each segment, substitutions, constellation effects, phenotype, and available empirical data. Any reduction should be based on evidence and precedent, not simply on which parent contributed the majority of segments.

Cells and primary materials

Section IV-2 appears to require IBC review for genetically modified cells, yet the scope language suggests that covered materials should also present a known or potential risk to human health. NIH should clarify whether all genetically modified cells are in scope or only those presenting a credible biosafety risk. Routine modifications of established human cell lines frequently do not materially increase biosafety risk. NIH should create an exemption or notification category for modifications that do not introduce an infectious, toxic, oncogenic, mobilizable, integrating, or otherwise hazardous function and that do not alter susceptibility in a way that creates a material hazard.

“Primary cells that may be contaminated by adventitious agents” is similarly overbroad because, absent adequate testing and provenance, most primary human or animal cells may harbor adventitious agents. NIH should distinguish established screened commercial sources; human materials already addressed through occupational bloodborne-pathogen frameworks; nonhuman-primate materials; cells from species associated with specific zoonoses; cells intentionally exposed to agents; and materials with epidemiologic or diagnostic indications of infection. Full IBC review of every use of untested primary cells would be disproportionate.

Cell-free nucleic acids

The draft does not adequately address hazardous nucleic acids before their introduction into a cell or organism. Infectious viral genomes, full-length infectious clones, and nucleic acids complexed with lipids or other delivery systems can present meaningful risk even while cell-free. The policy should explicitly cover cell-free nucleic acids when they are inherently infectious, encode a regulated or high-consequence product, constitute a substantially complete infectious genome, or are formulated or manipulated to facilitate cellular entry. Risk categories should account for genome polarity, need for helper functions, delivery vehicle, route of exposure, stability, quantity, and the plausibility of initiating infection or toxic expression. The policy should be harmonized with Federal Select Agent regulations, which expressly cover nucleic acids capable of producing infectious forms of select-agent viruses and certain nucleic acids encoding regulated toxins.

Selection and enrichment

It is appropriate that the concept of genetic modification is not limited to conventional molecular cloning and includes stable changes introduced through passaging, reassortment, chemical treatment, or

radiation. The framework should go further and address selection or enrichment processes that materially change the hazard of a population without necessarily creating an additional genetic change during the research. For example, isolating and expanding an antibiotic-resistant subpopulation from a heterogeneous clinical specimen can greatly increase concentration, purity, and exposure consequence even if the resistance determinant was already present. Similar concerns arise when selecting host-range variants, enriching preexisting escape mutants, or concentrating an infectious agent. The policy should regulate material changes in phenotype, concentration, purity, and exposure potential, not only the mechanism by which the underlying genotype arose.

Category structure

Section IV-2 broadly includes genetically modified cells, viruses, and organisms, then separately lists wild-type or genetically modified RG2 biological agents for which lower containment is requested. The relationship between these clauses and Section IV-3 is unclear. NIH should explain whether this provision is intended to govern an initial request to work below standard containment, subsequent work conducted under a previously approved lower-containment determination, or both. A coherent structure would mirror the treatment of RG3 and RG4 agents: place the initial request for a novel lower-containment determination at the appropriate higher review tier, publish or otherwise catalog the resulting precedent, and permit subsequent qualifying uses through a lower institutional tier unless the agent, modification, manipulation, or facility materially differs. The final policy should eliminate redundant clauses and provide a decision tree showing how agent RG, modification status, procedure, prior NIH determinations, and requested containment interact.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft's mandatory public-posting regime is excessive and insufficiently connected to risk reduction. Current NIH policy already requires public posting of approved IBC minutes for meetings held on or after June 1, 2025, and the draft would go substantially further by mandating a template, a continuously updated public IBC roster, public incident reports, NIH responses, institutional procedures, staff-training synopses, and multi-year posting obligations. Transparency is legitimate, but disclosure should have a defined safety purpose and be calibrated against privacy, security, proprietary, personnel recruitment, and biosecurity concerns. Detailed public accounts of protocols, vulnerabilities, incidents, personnel, and deliberations may deter candid discussion and committee service without improving laboratory practice. The draft refers to "appropriate and allowable redactions" but does not provide sufficiently concrete, uniform standards, leaving institutions exposed to inconsistent disclosure decisions.

The policy should require public posting of high-level governance information and de-identified aggregate safety outcomes, while making detailed protocol records and deliberative materials available to NIH for oversight rather than automatically publishing them. At a minimum, NIH should establish explicit redaction rules; protect security-sensitive, proprietary, personnel, medical, and dual-use information; permit role-based rather than named public rosters where appropriate; and require incident summaries that emphasize causes, corrective actions, and lessons learned rather than operational details.

6. Other feedback relevant to this resource: A six-month effective date is unrealistic for a policy that applies to new and ongoing work, including non-NIH-funded research, and requires new assurances, protocol triage, committee procedures, web infrastructure, templates, training, records systems, and likely additional personnel. The final policy should provide at least 24 months after publication of all operative guidance and should use phased implementation. A reasonable sequence would be institutional governance and assurance infrastructure; prospective review of newly initiated higher-risk work; transition of active higher-risk protocols; and then migration of lower-risk and legacy protocols. NIH should also provide model forms, decision trees, standardized definitions, training modules, and a mechanism for institutions to obtain binding interpretations during implementation.

Before finalization, NIH should:
1. Reissue a substantially revised draft together with all binding templates and implementation guidance.
2. Remove slogans, including “gold-standard”, and replace them with defined, measurable policy objectives.
3. Preserve PI ownership of experiment-level risk assessment while defining proportionate IBC and NIH review roles.
4. Define material amendments and create streamlined amendment procedures for changes that remain within previously approved risk parameters.
5. Add exemptions, notification pathways, staff review, delegated review, and umbrella protocols for low-risk work.
6. Conduct an administrative-burden and federal-capacity analysis and provide implementation support.
7. Replace the six-month deadline with a phased period of at least 24 months after all guidance is final.
8. Narrow and operationalize “potential risk,” “emerging,” “novel,” “low-risk transgene,” “well-characterized cell line,” and related terms.
9. Add a technically complete framework for viral vectors, replicons, helper systems, infectious clones, and clinical gene-delivery platforms.
10. Clarify treatment of cell-free infectious or toxin-encoding nucleic acids.
11. Rework influenza provisions around phenotype and consequence rather than majority-segment arithmetic.
12. Calibrate genetically modified cell and primary cell review to credible risk.
13. Address selection and enrichment that increase hazard without necessarily introducing a new mutation.
14. Establish a coherent One Health and interagency jurisdictional framework.
15. Replace automatic detailed public disclosure with risk-informed transparency, uniform redaction rules, and de-identified safety reporting.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: My main concern with the scope of this new policy is the lack of oversight of plant work. Although plant work does not directly affect human health, the consequences of incidents or an escape from containment could be similar in regards to effect on communities. As someone who lives in an agricultural area, this could have a negative effect on the businesses and the people who live here.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: This feedback is in regards to the Incident Reporting form as the parent of college students. My issue with this form is that the PI's name will be listed on the form that will be posted on the website. By posting the specific lab an incident occurred in, with the level of detail also required from this form, I'm concerned the medical confidentiality of students who may be involved in incidents will not be able to be protected.

6. Other feedback relevant to this resource: N/A

130. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/9/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy is extremely general and difficult to interpret. For example, Section IV-1 says that NIH will need to approve 1. Zoonotic agents that the BMBL does not give a risk group or minimum containment level. The BMBL does not have risk groups except those it references from the NIH Guidelines. Additionally, it doesn't give a containment level for many specific agents because the the majority of zoonotic agents that are known are given risk groups in the NIH Guidelines. Is the NIH prepared to review and approve all of the agents not listed in the BMBL? The BMBL is not an agent-specific resource.
2. Initial requests to lower containment for research involving wild type of genetically modified RG3 or RG4 biological agents (e.g., experiments with attenuated or replication-defective constructs). Does this refer to replication-defective lentivirus vectors that the NIH had previously stated could be safely used at BSL-2 (e.g., Biosafety Considerations for Research with Lentiviral Vectors file on NIH OSP website)? Does the NIH have the personnel in place to approve the amount of requests to work with replication-defective lentivirus vectors that will need to be submitted, reviewed, and approved immediately to not halt research?

What does GDMO stand for (I know, but some may not)? It is written throughout the policy but is not described or defined anywhere. In fact, Section IV-2 even lists gene drive modified biological agents as a separate entity from GDMO (that section says "e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs").

Section IV-2: what does "certain" vectors mean? How do we interpret which vectors are applicable? Many areas of the policy mention very general agents and materials, with no guidance on what is meant. Another example of the generalized confusion is Section IV-3 that Research conducted with transgenic organisms at BSL-1/ABSL-1 needs to be reviewed by the IBC (or a delegated review). Does this include the purchase, housing, breeding, and experiments that do not involve administration of any biological substances for every transgenic rodent line that is obtained from a vendor, even though decades of use of these rodents has shown that the majority do not have any risks associated to the humans or the environment? Most of the risks associated are related to animal care concerns (e.g., they are

immunocompromised and require specific care and containment practices to protect the animal).

Additionally, this policy is meant to modernize the current guidelines being used. Yet, "transgenic" is an older term used when transgenic animals were the only type of modification possible. That is no longer the case (e.g., site-directed, edited, etc.). Using terms like "transgenic", without a clear definition of what the policy means by that word, is another route of misinterpretation by those trying to be in compliance with the policy. "Transgenic" is one of the areas many IBCs have had dedicate to clarifing with their researchers to make sure all applicable work was reported to the IBC currently.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): What are the NIH's plans to approve all of the institutional assurances in a time frame to not stop research from being performed, and without jeopardizing the ability of researchers to maintain their funding award progress reporting deadlines? The draft policy says that no research can be performed that is applicable to the policy until the assurance is approved by the NIH, once the policy is finalized. How is this feasible, when the institutions do not even have a template or information for submitting the assurances before the policy is finalized. This is again another forced non-compliance. One moment the institutions will be in compliance with the NIH Guidelines, and then suddenly they will be out of compliance with the new NIH policy because the NIH OSP does not have the resources to approve all of the assurances in a timely fashion (this is based on concerns related to the current timelines provided by our IBC for NIH OSP approving IBC roster updates).

3. Continued utility of Risk Groups: Removing risk groups as part of a risk assessment is irresponsible. The required containment practices and the risks associated with specific organisms are different things. To clump everything as a biosafety level goes against the goal of strengthening oversight of biosafety. It is easy enough to include a step in the risk group analysis to include assessment for genetic modifications. It would be similar to how organisms proven to be attenuated (e.g., FDA-approved vaccine strains) have already been given a lower risk group whereas those not validated yet maintain the same risk group as the wild type. As long as clear reasoning is applied to the risk group designation method, there is no reason that it is not applicable to all organisms and modifications. It is an easy tool for even students to use- what happens if I am exposed to this organism, are there potential treatments, and "this is why they are making me follow these requirements when using it". The BSL does not tell you anything about why you need to use the practices being required and what can happen if you are exposed.
The BSL is part of the mitigation plan after knowing the risks of the organisms and procedures; not the assessment itself.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Requiring minutes to be posted "immediately" after approval is not a responsible term to use in a policy. If a deadline is being given it needs to be a realistic and feasible time-frame. "Immediately" does not take into account what is required to post items on a website (most institutions do not allow people within a department to just upload items. There are procedures to follow), and what happens when a person in the IBC or the website side is out of the office? Without taking realistic abilities into account for this type of request, a requirement of "immediately" is a forced non-compliance at some point in time for every institution. And not posting the minutes immediately in no way affects the actual safety and oversight of the

research; it only affects the timeliness of human curiosity for a meeting that happened in the past, which should not be the priority of a biohazard policy. Transparency is important, but not at the expense of institutions not providing appropriate time and resources to actually making sure the researchers are maintaining biosafety and biosecurity compliance in an attempt to reach an unattainable goal of posting items online.

When the instructions for posting things online has unattainable timelines, and is more structured and is better clarified, than the information in the policy for mitigating the risks associated with the research itself, there is a problem. The policy seems to have been written with honest concerns raised but without addressing how the risks should be mitigated. And so those applicable to the policy are left with no choice but to have widely different interpretations of what is being said in the policy, what they are being asked to do, and how they are supposed to be in compliance. The NIH Guidelines had initially been written by scientists who were listening to the concerns of others about the research being done, and so it was written to be understood by those performing tasks applicable to it. The new draft policy is essentially a list of concerns about research with biohazardous agents that need to be addressed, but gives no clear guidance on how to do so.

Role - Other: Laboratory Director

Date Submitted: 10/9/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Under the proposed requirements, I have concerns that the reporting policy is too broad and does not distinguish between routine, low-risk incidents and events that pose a serious biosafety concern. While transparency and accountability are essential, requiring public disclosure of every incident, including minor scratches or injuries that require only routine first aid, may be disproportionate to the actual risk. I worry about the implications it may have for the institution being broadcasted on a public-facing page. Specifically, if every minor incident must be reported it might discourage faculty PIs from training undergraduates within their laboratories.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

132. University of Wisconsin–Madison

I am responding: On behalf of an organization

Name: Dorota Grejner-Brzezinska

Name of Organization: University of Wisconsin–Madison

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/9/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: An effective biosafety and biosecurity policy is risk-based, technology-agnostic, and written to allow flexibility for local implementation. By empowering IBCs to set requirements based on risk assessment and removing most of the prescriptive language, the draft NIH Policy largely succeeds in achieving this.

One of the stated goals of the NIH Biosafety Modernization Initiative is to remove red tape for low-risk research. However, the expanded and unclear scope of the draft policy, in addition to new requirements under the policy, will increase the administrative burden for our IBC, Biosafety Program, and PIs. Areas where there is a lack of clarity or an increase in administrative burden are called out in comments for specific sections below.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Section IV. Categories of Oversight for Research Based on Risk
• Overall, we agree with the categorization of research into the three categories described.
o We appreciate that the categories are defined by the level of risk, and that only higher risk research requires review and approval from NIH.
• Some agents are not mentioned in this categorization and should be explicitly added to avoid confusion.
o We recommend the following be added to “Requires IBC Review and Approval Before Initiation”:
o Genetically modified RG3 and RG4 biological agents when lowering of containment is not requested
o The addition of an antibiotic or antiviral resistance trait to a pathogen that would negatively impact treatment of infection by that pathogen in humans
o We recommend the following be added to “Requires Review and Approval Before Initiation and May Be Delegated”:
o Genetically modified RG2 biological agents when lowering containment is not requested
Section IV-1. Research That Requires NIH and IBC Approval Before Initiation
• Overall, we agree that only the highest risk research should require NIH approval.
o Similar to above, the sentence “Research involving … agents for which the RG classification or a

recommendation for minimum containment level is not available in the BMBL" is confusing. BMBL does not contain risk group information. As stated above, we recommend that this be clarified and that multiple sources be allowed for determining risk group, such as the Americal Biological Safety Association Risk Group Database, Government of Canada Pathogen Safety Data Sheets, and a searchable list or database to be created and maintained by NIH.
o We recommend that established replication incompetent HIV-based lentiviral vector systems be explicitly excluded from requiring NIH approval for lowering containment of genetically modified RG3 agents. Alternatively, these should be included in the published list of approved determinations for lower containment when the policy goes live.

Section IV-2. Research That Requires IBC Review and Approval Before Initiation
• Clarifications are needed to properly categorize research in this category.
o The bullet "Research involving genetically modified cells, viruses, or organisms other than plants" seems to overlap with bullets under Section IV-3. Does this include all genetically modified cells? Viral vectors? Transgenic rodents? What is meant by "certain vectors"? Subsets of these that fall under delegated review should be explicitly excluded here.
o As stated above, it is not clear whether the intent is for the policy to cover all GDMOs, or only those that pose a risk or potential risk to human health (e.g., vectors of human disease). Plants are excluded elsewhere, but would gene drive modified plants be in scope?
o What is meant by "gene drive modified biological agents"? How does this differ from GDMOs?
o The wording of the bullet "Research involving toxins listed as Select Agents" does not align with definitions under the Select Agent Regulations. Toxins are not "select agents" they are "select toxins".
• Primary cells that may be contaminated by adventitious agents should be removed or limited.
o It is impossible to rule out the possibility of adventitious agents in primary cells, even with extensive testing, making this bullet unnecessarily broad.
o Primary human cells that pose a risk solely due to the potential for bloodborne pathogens are already covered by the OSHA Bloodborne Pathogen Standard 29 CFR 1910.1030.
o Primary animal cells not known or suspected of carrying zoonotic pathogens should be out of scope of the policy and not require IBC review.
o If kept, we recommend revising this to "Research with primary cells that are known or may be reasonably suspected to be contaminated with human or zoonotic pathogens not covered by the OSHA Bloodborne Pathogen Standard 29 CFR 1910.1030" and moving this to the delegated review category.
• We agree with the inclusion of clinical research but recommend revisions to the wording for greater clarity.
o We appreciate the exclusion of FDA regulated expanded access from the policy.
o "Products" is vague and should be amended to specify biological products that pose a known or potential risk to human health, such as microbes, viral vector systems, or biological toxins. As written, this could be interpreted to include chemical or radiological agents (which are outside the purview of the IBC) or biologically derived materials that pose little to no exposure risk (e.g., plasmids, antibodies).
o The inclusion of shedding as a criterium for IBC review may be problematic, as shedding data is not always available. Integration data may also not be available. We recommend adding "or for which the potential for shedding, replicating, or integrating is unknown".

Section IV-3. Research That Requires Review and Approval Before Initiation and May Be Delegated to an

Individual or Subgroup of IBC Members
• Overall, we agree that lower risk work should not require review and approval from the entire IBC prior to initiation.
o New low-risk experiments and minor amendments to previously approved research currently must wait for the next convened IBC meeting, which can cause delays to research. Delegated review will reduce wait times.
o Delegated review will also lighten busy IBC meeting dockets, freeing up more in-meeting time for discussion.
• The lowest risk research should be excluded or limited to reduce unnecessary administrative burden.
o The creation of a delegated review category does not reduce administrative burden. PIs still need to create submissions, and submissions still need to be processed and tracked.
o With the expansion of the policy to include wild type agents, toxins, and prions, the number of required submissions will increase.
o As written, the draft policy could be interpreted such that many agents previously exempt under the NIH Guidelines (e.g., RG1 E.coli and S. cerevisiae host vector systems and many transgenic rodents) now require delegated review. This creates an administrative burden with no added safety.
o The inclusion of transgenic organisms at BSL-1/ABSL-1 should be limited to those that pose a known or potential risk to human health. Under the current NIH Guidelines, many transgenic rodents purchased and bred at BSL-1/ABSL-1 are exempt from IBC registration requirements. Removing this exemption will significantly increase the number of registrations that the institution must process, review, and track. This adds significant burden to both PIs and IBCs with no added safety.
o We recommend explicitly excluding research involving genetically modified common animal models that pose little to no risk to human health, such as laboratory-bred rodents, fish, frogs, fruit flies, and non-parasitic nematodes at BSL-1/ABSL-1.
o Since RG1 organisms by definition do not cause disease in humans, “research with genetically modified RG1 biological agents” should be refined to “research with genetically modified RG1 biological agents that have been modified such that they pose a risk to human health (e.g., expression of a toxin or prion)”.
• Clarifications are needed to properly categorize research in this category.
o It is unclear what is considered a “minor amendment”. We recommend more explicit wording such as “amendments to previously approved research where there is no increase in risk”.
o Integration of viral vectors may depend on viral load. Is there a defined cutoff for what is considered “integrating”?
o As mentioned above, the terms “low risk transgenes” and “well-characterized cell lines” are not defined.
o As mentioned above, “biological toxin proteins not on the Select Agent list” should be revised to “biological toxins not listed in 42 C.F.R. Part 73 as Select Toxins” as not all toxins are proteins and none are technically “select agents” but rather “select toxins”.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): We have no comments on this section.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The University of Wisconsin-Madison thanks the NIH for providing us with an opportunity to comment on the Draft NIH

Incident Reporting Template. We are writing on behalf of the University to provide our feedback on the template.

We appreciate that the NIH has created templates in an effort to help institutions comply with the new Biosafety Policy. One of the stated goals of the NIH Biosafety Modernization Initiative is to reduce the administrative burden of biosafety programs to allow resources to be effectively allocated. However, in its current form, the draft template for incident reporting will increase administrative burden and create personal and institutional vulnerabilities.

Specifically:
• Posting all incident reports on a public-facing website will disincentivize reporting.
o Effective incident reporting must be non-punitive. Publicizing incidents will deter reporting and allow unsafe conditions or practices to persist.
o Even if redacted, incident reports often contain enough information to identify individuals that were involved, particularly in small laboratories.
o We recommend replacing the requirement to post all incident reports on a public-facing website with a requirement to publish aggregated and anonymized incident data.
• Posting all incident reports on a public-facing website creates an administrative burden.
o Due to their volume, institutions with robust research programs may have a higher number of incidents and thus many incident reports. Reviewing, redacting, and posting these on a public-facing website will require significant additional time and effort from already over-burdened safety and compliance programs without a commensurate benefit to the public. Publishing aggregated and anonymized incident data would reduce this burden while also providing transparent and timely public information.
• The mandatory template contains information that will endanger individual privacy protections.
o Good-faith reporting of incidents should not result in retaliation or adverse employment consequences. Best practice dictates that identifiable worker information should be limited to individuals with a legitimate need to know.
o The inclusion of position titles could lead to identification of individuals involved in incidents. Institutions should have the flexibility to describe individuals more generically (e.g., “employee” or “researcher”).
o IBC members, BSOs, and other biosafety professionals typically do not and should not have access to private medical records. Medical treatment and recommendations for medical treatment should remain private between an individual and their medical provider. This is particularly true when treatment information could reveal details about an individual’s personal health status. Including this information in the investigation and subsequent report violates this privacy.
• Grant information should not be required for incident reporting.
o It is not always immediately evident what grant(s) covers research involved in a specific incident.
o Having to investigate and determine the grant(s) or application(s) connected to the research is an increased administrative burden at odds with NIH’s objectives of reduced red tape and prompt reporting.
o Inclusion of grant information in incident reports will deter reporting. To be effective, incident reporting must be non-punitive. Connecting incidents to specific grants gives the perception that funding will be jeopardized by reporting. This creates a safety culture where unsafe conditions and practices go unaddressed, causing greater harm.

• The use of a mandatory template for initial notification of incidents to the NIH is unduly burdensome.
o There is often very little information available when incidents are initially reported to the IBC, Biosafety Office, or Research Office. Forcing the use of a form that may be largely blank wastes time and creates unnecessary paperwork.
o We recommend that institutions be given the option to send an email for initial notification of incidents to the NIH as is currently allowed. This path already provides an efficient mechanism for immediate reporting.
• The template could be improved by making it more concise.
o As mentioned above, we recommend removing fields related to funding information: NIH grant or contract number, NIH funding institute or center, NIH program officer name and email address.
o We recommend removing the field for reporting to other agencies. There is no clear purpose for including this information.

UW-Madison is committed to protecting our personnel and community and we are proud of our robust safety programs. We ask that the NIH allow greater flexibility for how institutions handle incident reporting to reduce the ever-growing administrative burden of research compliance and make local judgements to protect their personnel.

The University of Wisconsin-Madison thanks the NIH for providing us with an opportunity to comment on the draft NIH template for Institutional Biosafety Committee (IBC) meeting minutes. We are writing on behalf of the University to provide our feedback on the template.

We appreciate that the NIH has undertaken efforts to create templates to help institutions comply with the new Biosafety Policy. One of the stated goals of the NIH Biosafety Modernization Initiative is to reduce the administrative burden of biosafety programs to allow resources to be effectively allocated. However, in current form, the draft template for IBC meeting minutes will increase administrative burden and create vulnerabilities for US research.

Specifically:
• The use of a mandatory template will in many cases increase the amount of effort needed to generate IBC meeting minutes.
o Many IBCs use software to manage their meetings, including generation of minutes. For example, at UW-Madison our online software will automatically generate IBC meeting minutes based on information entered when the motions are recorded. Having to use a mandatory template will require us to either do extensive reprogramming of the software (which may not be possible) or create IBC meeting minutes manually instead.
o Manually generating IBC meeting minutes will be especially burdensome for institutions with large research portfolios. For example, in the last five years the UW-Madison IBC has reviewed an average of 326 registrations per year. With the expanded scope of the new NIH Biosafety Policy, this will only increase.
• The mandatory template includes too much detail.
o We appreciate the NIH's acknowledgement that redaction of minutes is appropriate to protect private or proprietary information, including, for example, information that would compromise institutional or

national security.
o While we applaud the NIH's drive for transparency, the level of scientific detail asked to be included in the minutes is not accessible to the majority of the public. To demonstrate to the public that the IBC is fulfilling its responsibilities, the information in the minutes should be accessible to a non-scientific audience. Descriptions should be less technical and more descriptive.
o We recommend the examples for the "Project Overview" and "Risk Assessment and Discussion" in the template be revised. For example, "The amendment proposes to add experiments using a replication-incompetent viral vector to express non-oncogenic, non-toxic proteins in established human cell lines at BSL2" captures the type of work and level of risk with less scientific and experimental detail.
• The template could be improved by making it more concise and reorganizing some sections for greater clarity.
o The section on "Quorum" is superfluous since the minutes list the IBC members present and no meeting business can occur without quorum.
o "Review of Prior Business" and "New Business/Additional Topics" could be combined into a single section for "Other Business".
o The line where "New IBC Registrations and Amendments for Review (repeat for each registration)" ends is unclear.
o The section "Readout of Any Projects Approved by Delegated Review" is embedded in the middle of the "New IBC Registrations and Amendments for Review (repeat for each registration)" sections, which is confusing. We recommend moving this section to before or after the new registrations and amendment for review.
o "Occupational Health Representative Review (if applicable)" can be incorporated into the "Risk Assessment and Discussion" section.

As a public institution, UW-Madison is committed to documenting the exceptional work that our IBC does to review and oversee research for the NIH and the public. We ask that the NIH allow greater flexibility for how institutions may fulfill documentation requirements to reduce the ever-growing administrative burden of research compliance and make local judgements to protect their personnel.

Thank you for your consideration.

6. Other feedback relevant to this resource: General Definitions
• There are several important definitions that are missing and should be added. These include the following:
o Risk groups
o Biosafety level
o GDMO
o Incident
o Exposure and potential exposure
o Release
o Adventitious agent
o Low risk transgene
o Well-characterized cell line
o Higher risk manipulation

o Enhanced containment
• In addition, several definitions are vague or ambiguous and should be clarified.
o The overall use of “agent” in definitions and throughout the policy is unclear (e.g., emerging agent, novel agent). Does this refer to microbes, other organisms, parts and pieces of microbes or organisms?
o The definition of “biological agent” will be confusing for scientists that use this term more generally. We recommend replacing this term with “biohazardous agent” for greater clarity. If the term “biological agent” is kept, we recommend adopting the definition from 18 USC 178 for better alignment across federal agencies.
o “Emerging agent or organism” should specify that it is biological in nature and is known to or can be reasonably expected to pose a potential risk to human health.
o “Novel agent or organism” should specify that it is biological in nature and is known to or can be reasonably expected to pose a potential risk to human health.
o We recommend removing “or animals” from the definition of “prions and self-aggregating proteins” since animal health is outside the scope of the policy.
o “Toxin” is defined as a protein or peptide, but not all biological toxins are proteins.
o The phrase “causes harm to humans” in the definition of “toxin” is unclear and could be interpreted to include many proteins that are not typically considered biological toxins. We recommend revising this definition to include a minimum LD50 and adopting the definition from 18 USC 178 for better alignment across federal agencies.
o The definition of “zoonotic” should specify that it refers to agents that are biological in nature.

Description: Combined response on Biosafety policy, IBC minutes, and incident reporting template

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of the proposed policy is insufficiently defined and contains significant ambiguities that must be resolved before implementation. The current language creates substantial risk of inconsistent interpretation among institutions and will result in uneven oversight across the research enterprise. The policy defines covered research as that involving a "known or potential risk to human health," yet fails to establish any objective threshold for what constitutes a potential risk. As written, virtually any biological material could be interpreted as falling within scope, rendering the definition overly broad and operationally unworkable. NIH must provide clear criteria for determining when a biological material or activity is subject to oversight.

The policy also relies on numerous undefined terms that directly affect scope and applicability. Terms including "organism," "emerging biological agent," "emerging technologies," and "manipulations" must be explicitly defined. Failure to define these terms will inevitably result in inconsistent institutional interpretations and unequal regulatory treatment of similar activities.

The scope statement is internally inconsistent. The policy is ostensibly focused on risks to human health, yet numerous provisions require assessment of environmental impacts and ecological risks, including mandated expertise in environmental risk assessment and representation of community interests related to environmental protection on the IBC. NIH must either explicitly incorporate environmental risks into the stated scope of the policy or remove requirements that extend beyond the stated purpose of protecting human health.

The policy further fails to clearly articulate the treatment of several research categories that commonly require institutional review, including research involving human-derived materials, stem cells, established cell lines, attenuated organisms, nonreplicating vectors, and biological materials that may present indirect or conditional risks. NIH must provide explicit guidance, exclusions, and examples to prevent institutions from unnecessarily expanding oversight of low-risk activities.

Additionally, the policy's treatment of toxins, prions, self-aggregating proteins, and zoonotic agents is not fully reconciled with the definition of biological agents. NIH must clarify how these materials fit within the overall biohazard framework and establish a consistent regulatory approach across all categories of covered materials.

Finally, the policy does not adequately address risks arising from the use of biological agents in animal research. NIH must clarify whether secondary exposures, shedding, transmission, animal-associated risks, and occupational hazards associated with animal studies fall within the intended scope of oversight. This gap is particularly significant given the widespread use of animal models in biomedical research.

Additional specifics:
The phrase "known or potential risk to human health" is overly broad and lacks objective criteria. NIH should establish a threshold for oversight or provide examples of activities that are outside the policy's scope. As written, the definition could encompass virtually all work involving human-derived materials, cell culture, or microorganisms

The policy repeatedly references environmental protection and ecological risk assessment, yet the scope is described as human-health focused NIH must either revise the scope to explicitly include environmental risks or remove requirements that extend beyond a human-health framework. The policy currently contains a fundamental inconsistency regarding the risks it intends to regulate.

NIH should explicitly state whether human stem cells, induced pluripotent stem cells, primary human tissues, and established cell lines are intended to fall within the scope of this policy when they are not genetically modified and do not contain infectious materials.

NIH should clarify the boundaries between laboratory research, clinical research, and environmental release activities to ensure consistent application of oversight requirements.

The policy does not adequately address secondary risks arising from animal research, including shedding, transmission, environmental contamination, escape, occupational exposure, and risks occurring after administration of biological agents to animals. NIH should expressly address these scenarios within the scope and risk-assessment framework.

Please define:
• Potential risk to human health
• Organism
• Emerging biological agent / Emerging agent
• Emerging technologies
• Manipulations
• Product
• Clinical product
• IBC Delegate

• Significant risk to human health
• Records related to awards

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed tiered oversight framework lacks sufficient clarity regarding the division of authority between NIH and institutional biosafety programs. As drafted, the policy creates uncertainty regarding whether NIH intends to establish general oversight expectations or exercise direct regulatory authority over specific research activities. This ambiguity must be eliminated before implementation.

The policy repeatedly requires institutions to obtain NIH authorization or determination before proceeding with certain categories of research involving emerging, novel, or zoonotic agents. However, NIH provides no description of how such reviews will occur, what standards will be applied, which NIH office will make decisions, or how long institutions should expect to wait for a response. A regulatory requirement that lacks defined procedures and timelines is unacceptable and creates significant operational uncertainty for institutions and investigators. NIH must establish transparent review pathways and enforceable review timelines prior to implementing these requirements.

The policy appropriately recognizes the role of Institutional Biosafety Committees but does not sufficiently acknowledge that IBCs possess direct knowledge of local facilities, personnel qualifications, operational practices, and institutional risk management systems. NIH should not unnecessarily centralize decisions that can be effectively evaluated at the institutional level by qualified experts. Federal oversight should be reserved for truly novel, unprecedented, or exceptionally high-risk research activities. Routine risk assessment and containment determinations should remain the responsibility of institutions.

The proposed framework will also create unnecessary duplication unless NIH commits to publicly posting biosafety determinations involving emerging, novel, and zoonotic agents. Institutions should not be required to repeatedly submit substantially similar requests for NIH review when prior precedential determinations already exist. NIH must establish and maintain a publicly accessible repository of containment decisions, interpretations, and policy determinations to promote consistency and transparency throughout the research community.

Most importantly, the final policy must maintain a strict relationship between risk and oversight burden. The expansion of policy scope cannot be allowed to result in low-risk activities being subjected to the same level of review and administrative requirements as higher-risk research. Such an outcome would divert limited institutional resources away from activities that present meaningful biosafety concerns. The final policy must preserve streamlined review mechanisms, delegated review authorities, administrative determinations, and clearly defined exclusions for low-risk activities. Oversight resources should be directed where they provide measurable biosafety benefit rather than applied uniformly across all covered research.

In its current form, the tiered oversight framework does not provide sufficient clarity regarding responsibilities, authority, timelines, or mechanisms for federal decision-making. These deficiencies should be corrected before the policy is finalized.

Additional specifics:
The policy repeatedly states that institutions must obtain NIH authorization before conducting certain activities involving novel, emerging, or zoonotic agents.

Which NIH office?
Review criteria?
Appeal process?
Required submission contents?
Timelines?

NIH should not impose a mandatory approval process without publishing review criteria, procedural requirements, decision authorities, and response timelines. Such information is necessary for institutions to effectively plan and conduct research activities.

NIH should establish target review timelines for all federally required determinations. Delayed decisions can significantly affect grant start dates, staffing, facility scheduling, and research progress.

NIH should publish all containment determinations, precedent-setting interpretations, approvals of containment reductions, and determinations involving emerging or novel agents. Institutions should not be required to repeatedly seek NIH review for issues that have already been evaluated and resolved.

The proposal appears to shift decision-making authority toward NIH while relying on institutions to perform the underlying risk assessments, monitoring, inspections, training, incident investigations, and compliance activities. NIH should clearly justify when federal review adds value beyond local expert review.

3. Continued utility of Risk Groups: Risk Groups (RGs) should be retained as the primary framework for hazard communication and initial agent characterization. RGs provide a widely understood, objective, and standardized method for communicating the potential hazards associated with biological agents and promote consistency across institutions. However, RG classification alone should not dictate containment requirements or determine the level of oversight. As has long been recognized, appropriate biosafety determinations require consideration of the specific characteristics of the agent, the nature of the proposed work, the procedures being performed, scale of use, routes of exposure, personnel expertise, available facilities, and other risk-mitigation measures.

The final policy should preserve institutional authority to conduct experiment-specific and site-specific risk assessments rather than replacing existing practices with prescriptive federal requirements. Institutional Biosafety Committees are best positioned to evaluate local facilities, personnel qualifications, operational practices, occupational health programs, and available containment capabilities. The policy should support, rather than diminish, this longstanding role.

The proposed definition of genetic modification warrants further refinement. As drafted, the definition includes changes resulting from passaging, reassortment, and chemical or radiological means in addition to deliberate genetic engineering. This approach could inadvertently subject conventional selection, adaptation, mutagenesis, strain improvement, and other routine laboratory activities to increased

oversight even when such activities do not result in increased biosafety risk. Oversight should be based on the characteristics and risk profile of the resulting agent rather than the method used to generate the change.

NIH should clearly distinguish deliberate genetic engineering from naturally occurring adaptation, laboratory selection, reassortment, passaging, and induced mutagenesis. Not all genetic changes create meaningful biosafety concerns, and oversight requirements should remain proportional to demonstrated risk rather than being triggered solely by the occurrence of genetic alteration.

The policy should also avoid rigid containment requirements that may conflict with established risk-assessment practices. For example, a universal minimum containment requirement for genetically modified organisms may not align with specialized systems used for arthropod research, aquatic organisms, greenhouse studies, ecological research, or other nontraditional research settings. Institutions should be permitted to utilize equivalent containment approaches when they provide comparable protection and are supported by appropriate risk assessment. NIH should develop technology-specific guidance where necessary rather than relying on broadly applicable containment mandates.

Similarly, provisions addressing influenza viruses should provide clear and objective criteria regarding when enhanced containment is warranted. Containment requirements should be based on demonstrated phenotypic characteristics and risk-relevant attributes rather than broad language that could encompass a wide range of constructs without regard to actual biosafety implications.

In summary, RGs remain an effective starting point for hazard classification and should continue to serve that function. The final policy should preserve institution-led, risk-based decision making; distinguish genetic engineering from other forms of biological change; and avoid prescriptive containment requirements that are not calibrated to the characteristics and risks of the specific research being conducted. This approach will promote both consistency and flexibility without creating unnecessary oversight burdens.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary compliance should be supported through access to publicly available guidance and national determinations rather than through additional oversight structures or administrative requirements. Institutions should be able to rely on published NIH containment determinations, risk classifications, guidance documents, and implementation resources rather than repeatedly requesting the same information. NIH should maintain a searchable database of determinations involving emerging, novel, and zoonotic agents and allow institutions to rely on published precedents where appropriate. The policy should also support flexible implementation models. Voluntary compliance should not result in additional reporting, approval, registration, certification, or assurance requirements that create administrative burden without corresponding biosafety benefit.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Comments on Draft Incident Reporting and Draft Meeting Minutes Templates

The draft incident reporting and meeting minutes templates impose substantial administrative burdens that are not justified by a corresponding improvement in biosafety oversight, risk management, or public safety. The proposed requirements significantly expand institutional documentation, review, and public disclosure obligations while providing little evidence that the additional processes will improve biosafety outcomes.

Meeting Minutes Template

The fundamental issue is that the minutes template appears to shift IBC minutes from documenting committee actions and decisions to documenting the underlying scientific review itself. That creates substantial administrative burden while providing little additional biosafety value. The quality of an IBC review should be judged by the appropriateness of its decisions and risk-management strategies, not by the length of its meeting minutes or incident reports.

The Template Converts Minutes into a Secondary Protocol Record. The proposed template transforms meeting minutes into a secondary protocol document by requiring extensive duplication of information already maintained within protocol submissions, risk assessments, training records, and institutional systems. This creates substantial administrative burden without improving the quality of biosafety review or oversight outcomes.

No Demonstrated Connection Between More Detailed Minutes and Better Biosafety. NIH has not demonstrated how increasingly detailed meeting minutes improve biosafety outcomes, incident prevention, containment practices, or regulatory compliance. Documentation should support committee decision-making and record institutional actions rather than serve as a duplicate scientific review record.

Requirement to Document Routine Business Creates Scope Creep. The accumulation of documentation expectations for routine operational activities substantially expands administrative workload while providing limited additional oversight value. The purpose of minutes should be to document committee actions and determinations rather than serve as a comprehensive institutional biosafety record.

Public Posting Creates Incentive to Over-Document and Then Over-Redact. The more information institutions are required to include in public-facing meeting minutes, the greater the burden associated with review, redaction, legal assessment, and public posting. Expanding minute content creates additional administrative work without strengthening biosafety oversight.

Incident Reporting Template

The most significant concern is the expansion of oversight and documentation requirements for incidents that do not warrant NIH reporting. The proposed policy requires institutions to investigate, document, review through the IBC, and publicly post information regarding incidents that NIH itself has determined are not significant enough to require federal notification.

This creates a new category of institutionally reportable and publicly disclosed events without demonstrating how such requirements improve biosafety. Requiring formal IBC review and public

posting of minor incidents, animal bites and scratches, routine first-aid events, and other low-risk occurrences represents regulatory creep that will consume institutional resources that would be better directed toward meaningful risk reduction activities.

Minor Incidents Are the Biggest Burden Issue. Requiring formal documentation and public posting of discussions regarding minor incidents that are not reportable to NIH represents a significant expansion of administrative obligations. Institutional resources should remain focused on significant biosafety events rather than generating public records for incidents that pose minimal risk and do not warrant federal notification.

Oversight should remain proportional to risk. Events that do not meet NIH reporting thresholds should generally remain subject to local management and corrective action processes unless there is a clear justification for additional review.

Particularly concerning is the use of the term"significant" without measurable criteria. Institutions cannot be expected to apply a consistent standard when the policy does not establish one. The inevitable result will be variability in reporting practices, inconsistent national data, and overreporting driven by institutional concern about regulatory scrutiny.

The proposal appears to assume that greater transparency is achieved simply by publishing more information. However, NIH has not demonstrated how public posting of minor incidents or extensive committee discussions improves biosafety performance, accident prevention, or public protection.

Recommendations

NIH should revise the templates to:

Focus reporting on significant biosafety events.
Establish objective reporting thresholds and definitions.
Eliminate public-posting requirements for non-NIH-reportable incidents.
Limit meeting minutes to committee actions, determinations, and votes rather than detailed scientific review narratives.
Avoid duplicative documentation requirements for information already maintained elsewhere in institutional oversight systems.

As currently drafted, the templates substantially increase administrative burden, expand oversight into low-risk institutional matters, and create new public disclosure obligations without demonstrating a meaningful improvement in biosafety outcomes.

6. Other feedback relevant to this resource: The success or failure of the proposed policy will depend less on the regulatory text itself and more on the quality, completeness, and usability of the implementation resources. These resources should focus on clarifying policy expectations, reducing ambiguity of the fundamental terms (e.g., significant, biological agent), while preserving institutional flexibility to develop oversight practices that are appropriate for their research activities, organizational structures, available expertise, facilities, and risk profiles.

Implementation resources should not create additional approval pathways, reporting requirements, prescriptive operational procedures, or de facto regulatory requirements beyond those expressly contained within the policy

NIH Must Clarify the Process for Novel, Emerging, and Zoonotic Agents: The policy requires institutions to seek NIH determinations for certain categories of agents but provides little operational guidance regarding how this process will function. If NIH intends to maintain a role in such determinations, NIH should clearly publish:

-Submission requirements
-Required supporting documentation
-Review criteria
-Risk factors considered during review
-Expected review timelines
-Processes for obtaining clarification

Institutions cannot effectively comply with requirements when the underlying review process is undefined.

NIH Must Publish Determinations and Policy Interpretations and maintain a publicly accessible repository. Institutions should not be required to submit repetitive requests regarding issues NIH has already evaluated. Publication of precedent-setting determinations would improve consistency across institutions while reducing administrative burden for both institutions, PIs, and NIH

Submitted via https://osp.od.nih.gov/comment-form-draft-nih-biosafety-policy-for-research-involving-biohazards/

Dear Associate Director Jorgensen:

Mass General Brigham appreciates the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112). Mass General Brigham is a not-for-profit academic health care system committed to patient care, biomedical research, education, and service to the community. The system includes two academic medical centers, Massachusetts General Hospital and Brigham and Women's Hospital, and specialty hospitals that include McLean Hospital, Mass Eye and Ear, and Spaulding Rehabilitation Hospital. The Mass General Brigham Institutional Biosafety Committee (IBC) provides centralized biosafety review and oversight for biological research conducted at these institutions. Mass General Brigham and its affiliated institutions receive NIH funding and conduct a substantial and diverse portfolio of basic, translational, animal, and clinical research subject to federal, state, local, and institutional biosafety requirements.

Mass General Brigham supports NIH's objective of establishing a contemporary, risk-based framework that promotes safe, responsible, secure, and accountable biomedical research. However, several proposed requirements would create substantial administrative burdens, introduce uncertainty, or potentially discourage transparent incident reporting without producing a corresponding improvement in biosafety.

Recommendations to Improve Reporting of incident reports

As currently drafted, Mass General Brigham has concerns about the proposed requirement to publish individual biosafety incident reports. The policy requires institutions to post all incident reports on a public-facing institutional website using the required NIH template. This includes both significant incidents reported to NIH and lower-risk incidents reviewed only by the IBC, such as certain animal bites, scratches, escapes, improper dispositions, and incidents at BSL-1/ABSL-1 or BSL-2/ABSL-2 for which only first aid is administered.

The public-posting requirement is materially different from public access to IBC meeting minutes. Incident reports contain concentrated information about a specific event, including the

individual(s), laboratory, and research activities involved. The required NIH template calls for an incident narrative, information about the biological material, investigation findings, root-cause analysis, and corrective actions. It also instructs institutions to write reports in lay language to promote public transparency.

Although the template prohibits personally identifiable information about individuals, it expressly requires the principal investigator's name to remain in the public report. Redaction is limited to proprietary or private information, confidential commercial information, and information whose disclosure would directly compromise institutional or national security.

These protections may be insufficient to prevent identification of affected personnel. In a small laboratory, specialized research program, or department with a limited number of employees, the combination of the principal investigator's name, biological agent or research material, incident type, general setting, personnel position, circumstances of the event, medical response, root cause, and corrective actions may allow colleagues or members of the research community to identify an affected individual even when the individual's name is removed.

Public posting may also discourage prompt reporting of minor incidents, suspected exposures, and near misses. Mass General Brigham requires personnel to report potential or overt exposures, suspected laboratory-acquired infections, and possible violations even when the individual does not seek evaluation from Occupational Health or an emergency department. Effective biosafety oversight depends on personnel reporting these matters promptly and candidly. The requirement to publish an individual report may create a perceived adverse consequence for reporting and may therefore weaken the reporting culture the policy is intended to strengthen.

Publication of institution-only incidents is particularly concerning. NIH has determined that these lower-risk incidents do not require federal reporting, yet the draft would require institutions to prepare and publish individual reports about them. The transparency benefit of publishing an animal scratch, minor first-aid event, or other lower-risk incident is unclear, while the potential effects on employee privacy, reporting behavior, institutional workload, and public interpretation are substantial.

NIH's proposed National Biosafety Data and Safety Analysis Center provides a more appropriate mechanism for public learning from biosafety incidents. Aggregated and de-identified analysis can identify recurring hazards, contributing factors, corrective actions, and national trends without exposing individual employees, laboratories, or institutions through event-specific public reports.

Mass General Brigham recommends the NIH:

- Remove the requirement that institutions publicly post individual incident reports.
- Require institutions to report applicable incidents to NIH and maintain appropriate institutional records without making each report public.

- Use the National Biosafety Data and Safety Analysis Center and NIH's annual incident summary to publish aggregated, de-identified information about national trends, recurring causes, and effective corrective actions.
- Exclude incidents requiring only institutional or IBC review from any public-posting requirement.
- If public posting is retained, limit it to a standardized public summary of a confirmed significant incident that was reportable to NIH.
- Do not require the public summary to identify the Principal Investigator, laboratory, department, affected personnel's position titles, specific location, distinctive agent or construct, medical response, or other details that could reasonably permit identification.
- Permit institutions to redact combinations of otherwise nonidentifying information when the combined information could reasonably identify an affected person, laboratory, or research program.
- Permit institutions to delay publication until the investigation, occupational health evaluation, corrective actions, legal review, and applicable employment processes are complete.
- Evaluate whether mandatory public disclosure could discourage reporting of minor incidents and near misses before imposing this requirement.

USE A RISK-BASED RENEWAL FRAMEWORK

The draft policy provides that IBC approval may not exceed three years, after which the investigator must submit a de novo registration for review. It does not explain the scientific or risk-based rationale for selecting a three-year interval or require the renewal pathway to account for whether the research, biological materials, procedures, containment, or applicable biosafety standards have changed.

Mass General Brigham has effectively used a five-year approval cycle for over 15 years. During each approval period, the principal investigator must review the registration annually to confirm that it accurately describes the research. Changes must be submitted prospectively through the amendment process, and scientific changes that may affect the biosafety assessment, receive BSO review and, when necessary, review by the convened IBC. The IBC may also shorten the approval period when warranted.

This combination of annual investigator review, prospective amendment review, and periodic comprehensive renewal provides continuing oversight throughout the approval period. The registration does not remain unchanged and unexamined for five years. Material changes in biological agents, recombinant or synthetic nucleic acid molecules, procedures, animal studies, laboratory locations, containment, or other risk-relevant elements are reviewed before implementation.

A five-year cycle also aligns more closely with the evolution of many funded research programs. New grants, competitive renewals, changes in scientific direction, and changes in personnel or

facilities frequently generate amendments or updated registrations during that period. Conducting a mandatory de novo review at three years may require an investigator to complete a full renewal shortly before a grant renewal or new project.

Mandatory de novo review every three years would substantially increase workload for investigators, BSOs, IBC staff, committee members, and institutional officials. Much of this additional effort would involve reconstructing and re-reviewing registrations for research that has not materially changed. The draft policy does not identify a biosafety benefit that would result from repeating a comprehensive review of unchanged work two years earlier than under a five-year grant review cycle.

The consequences associated with a lapse in approval may further shorten the practical renewal cycle. To prevent a registration from expiring because of an incomplete submission, investigator delay, committee scheduling, or the need for revisions, institutions may need to begin the renewal process many months before the three-year expiration date. The resulting operational cycle could approach two years, further increasing repetitive administrative review without a corresponding improvement in safety.

NIH should use a risk-based renewal framework that distinguishes unchanged research from research involving material scientific or biosafety changes. When the principal investigator confirms that the research remains unchanged, a BSO or qualified IBC delegate should be permitted to review the registration, verify the existing risk assessment and containment conditions, and renew the approval. The delegate should refer the registration to the convened IBC when the research has materially changed, the risk assessment is no longer adequate, relevant standards or best practices have changed, significant compliance concerns exist, or the reviewer otherwise determines that full committee review is warranted.

Mass General Brigham recommends the NIH:

- Permit IBC approvals for up to five years.
- Permit a BSO or other qualified IBC delegate to approve unchanged research after confirming that the risk assessment, containment, and approval conditions remain appropriate.
- If NIH retains the three-year maximum, permit streamlined delegated renewal of unchanged research rather than requiring a de novo review.
- Authorize temporary administrative extensions when a complete renewal was submitted before expiration and institutional review remains in progress.
- Preserve existing approvals through their current expiration dates rather than requiring early renewal solely to conform to the new policy.

ESTABLISH CLEAR, RISK-BASED THRESHOLDS FOR IMMEDIATE NIH INCIDENT NOTIFICATION

The draft policy requires institutions to notify NIH within 24 hours, or as soon as the institution becomes aware, of incidents considered to pose a significant risk to human health. The specified

categories include a confirmed or potential laboratory-acquired infection; a loss of containment or release with potential community risk; incidents at BSL-3/ABSL-3 or BSL-4/ABSL-4, including certain potential exposures, facility or equipment failures, and inventory or security issues; BSL-2/ABSL-2 exposures requiring agent-specific treatment beyond basic first aid; and compliance violations such as failure to obtain or maintain required IBC or NIH approval.

Mass General Brigham supports immediate notification when an incident presents a credible and significant risk of infection, transmission, environmental release, or harm to the community. However, several of the proposed thresholds are broad or undefined and could require immediate reporting before the institution has enough information to determine whether an event presents a significant risk.

Terms such as "potential laboratory-acquired infection," "potential community risk," "potential exposure," "agent-specific treatment," and "compliance violation" require objective definitions. Without clear thresholds, institutions may be required to report events based on a theoretical possibility rather than a reasonable assessment of likelihood and consequence. This could result in over-reporting of precautionary medical evaluations, minor deviations, contained equipment failures, or events for which subsequent investigation determines that no meaningful exposure or release occurred.

A potential laboratory-acquired infection should not include every illness that occurs following work with a biological agent. The threshold should require a reasonable basis to suspect a relationship between the illness and the individual's laboratory activities, considering the agent, symptoms, incubation period, exposure circumstances, and available occupational health assessment. Immediate notification may appropriately occur before causation is confirmed, but the initial assessment should establish that laboratory acquisition is reasonably plausible rather than merely possible.

Similarly, seeking medical evaluation or receiving prophylaxis does not necessarily establish that a meaningful exposure occurred. Medical professionals may recommend evaluation or precautionary treatment because information is incomplete, because the consequences of an unlikely infection could be serious, or because institutional procedures intentionally use conservative criteria. The current policy already recognizes this distinction for treatment related to possible adventitious agents, which is not reportable unless a laboratory-acquired infection results. NIH should apply a consistent principle to other precautionary evaluations and treatments.

The requirement to report potential releases involving facility or equipment failures at BSL-3/ABSL-3 or BSL-4/ABSL-4 also requires clarification. A failure of one component does not necessarily result in a loss of containment, particularly when redundant systems function as designed. Immediate notification should focus on failures that compromise containment or create a credible risk to personnel, the public, or the environment. Routine equipment malfunctions that

remain contained and are corrected through established procedures should be documented and reviewed institutionally but should not automatically require federal notification.

The treatment of compliance violations is also overly broad. Failure to obtain or maintain IBC approval is significant when covered research is conducted without required approval or after approval has expired. However, not every administrative discrepancy or delay materially compromises biosafety oversight. NIH should distinguish substantive noncompliance from administrative errors that are promptly corrected and do not affect containment, personnel safety, public health, or the environment.

The 24-hour period should begin when an appropriate institutional official, such as the BSO, IBC Chair, IBC office, or institutional official, has sufficient information to reasonably determine that the event meets the NIH reporting criteria. An incident may first be reported to a supervisor, Occupational Health, animal care personnel, facilities staff, or another institutional office without enough information to identify it as a reportable biosafety event. Starting the reporting period at the time of the underlying event, or when any institutional employee first becomes aware of it, would create an uncertain and potentially unworkable standard.

Mass General Brigham recommends the NIH:

- Limit 24-hour notification to incidents presenting a credible and significant risk of infection, transmission, environmental release, or material loss of containment.
- Define "potential laboratory-acquired infection" as an illness or condition for which laboratory acquisition is reasonably plausible based on an initial occupational health and biosafety assessment.
- Clarify that precautionary medical evaluation, diagnostic testing, vaccination, or prophylaxis does not independently make an event reportable when a meaningful exposure is not reasonably suspected.
- Define "potential community risk" using objective considerations such as loss of primary and secondary containment, agent transmissibility, environmental persistence, exposure pathway, quantity released, and effectiveness of the immediate response.
- Limit immediate reporting of facility or equipment failures to failures that compromise containment or create a credible risk to personnel, the public, or the environment.
- Clarify that failure of one component does not constitute a reportable release when redundant containment systems function as intended and no credible exposure or release occurs.
- Limit federally reportable compliance violations to substantive violations that materially compromise biosafety oversight or result in covered research being conducted without required approval or containment.
- Permit institutions to document and correct minor administrative discrepancies without immediate federal notification when the discrepancy does not affect safety or oversight.

- Start the 24-hour period when the BSO, IBC Chair, IBC office, institutional official, or another designated institutional authority has sufficient information to reasonably determine that the event meets NIH reporting criteria.
- Require the initial notification to include only information reasonably available at the time of reporting.
- Use a tiered framework that distinguishes immediate NIH notification, routine NIH reporting, and institution-only documentation.
- Permit periodic aggregate reporting of lower-risk events that NIH determines would provide useful surveillance information but do not warrant immediate notification.

CLARIFY THE EXCLUSION OF WILD-TYPE RG1 BIOLOGICAL AGENTS

The draft policy is unclear regarding whether research involving wild-type Risk Group 1 biological agents is subject to the policy. Section IV-3 states:

"[Note: Experiments involving RG1 wild-type biological agents are not subject to this Policy.]"

This exclusion is not clearly reflected in the policy's scope or definitions. Section II defines research involving biohazards to include research involving wild-type bacteria, viruses, fungi, or parasites that "cause disease in humans," and the definition of "biological agent" uses similarly broad language. Some organisms generally classified as RG1 may nevertheless have been associated with rare disease, opportunistic infection, or disease in unusually susceptible individuals. As written, the broader scope and definitional language could therefore be interpreted to include agents that Section IV-3 states are excluded.

To resolve this uncertainty, NIH should align the scope, definitions, and review categories by using language consistent with the BMBL and established Risk Group framework. Mass General Brigham recommends that the NIH define covered wild-type biological agents as:

"Wild-type biological agents that are associated with disease in healthy adult humans."

This language would more clearly distinguish covered wild-type agents from RG1 agents. It would also preserve Section IV-3 exclusion without relying on a note that could conflict with the broader operative language elsewhere in the policy.

Mass General Brigham recommends the NIH:

- Revise the scope and definition of "biological agent" to refer to wild-type biological agents "associated with disease in healthy adult humans."
- State expressly in the scope section that research involving wild-type RG1 biological agents is not subject to the policy.
- Apply the RG1 exclusion consistently throughout the scope, definitions, and review categories rather than placing the exclusion only in a note under Section IV-3.

- Clarify that the rare occurrence of opportunistic disease or disease in an unusually susceptible person does not necessarily bring an otherwise RG1 wild-type agent within the scope of the policy.
- Remove the bracketed note concerning wild-type RG1 biological agents from Section IV-3 and incorporate the exclusion directly and consistently into the policy's scope, definitions, and exclusions section.

CLARIFY THE REVIEW CATEGORY FOR PRIMARY CELLS THAT MAY CONTAIN ADVENTITIOUS AGENTS

Section IV-2 requires full IBC review of research involving "primary cells that may be contaminated with adventitious agents." The draft does not define "primary cells," "adventitious agents," or the degree of likelihood necessary to conclude that primary cells may be contaminated.

This requirement also appears inconsistent with the policy's risk-based review structure. Section IV-2 generally requires full committee review for research involving RG3 and RG4 wild-type biological agents, while Section IV-3 permits delegated review of research involving RG2 wild-type biological agents. As written, however, primary cells that may contain an RG2 adventitious agent would require full committee review. This could subject cells that are only potentially contaminated with an RG2 agent to a higher level of review than research conducted directly with the same wild-type agent.

The treatment of HIV requires clarification. Because HIV is classified as an RG3 biological agent, a broad interpretation of "may be contaminated" could require full committee review of virtually all primary human cells based solely on the possibility that the donor may have been infected with HIV. This would be inconsistent with the established approach of treating human blood, tissues, and other potentially infectious materials as though they may contain bloodborne pathogens and applying appropriate universal precautions, rather than presuming that every specimen contains an RG3 agent.

Routine primary human cells should not require full committee review solely because HIV or another bloodborne pathogen cannot be excluded with absolute certainty. Unless the cells are known or reasonably suspected to be HIV-positive, originate from a population with a substantial likelihood of HIV infection, or will undergo procedures that could propagate or concentrate HIV, the research should be eligible for delegated review. The use of universal precautions and appropriate containment should be considered part of the risk mitigation supporting delegated review.

The required review pathway should reflect the identity and Risk Group of any known or reasonably suspected adventitious agent, the likelihood that the agent is present, the available donor screening or product-testing information, and whether the proposed procedures could propagate, amplify, concentrate, or aerosolize the agent.

Mass General Brigham recommends the NIH:

- Define "primary cells" and "adventitious agents."
- Clarify whether HIV, hepatitis viruses, and other bloodborne pathogens potentially present in donor-derived materials are considered adventitious agents.
- Clarify that the theoretical possibility of HIV contamination does not automatically require full committee review of all primary human cells.
- Permit delegated review of routine primary human cells handled under universal precautions and applicable bloodborne-pathogen requirements.
- Permit delegated review when primary cells may contain an RG2 agent, consistent with the delegated-review pathway for work conducted directly with wild-type RG2 biological agents.
- Reserve full committee review for primary cells known or reasonably suspected to contain an RG3 or RG4 agent, including cells from donors known to be infected, or for procedures likely to propagate, amplify, concentrate, or aerosolize such an agent.
- Explain how donor screening, population prevalence, product testing, commercial sourcing, repository characterization, fixation, validated inactivation, and other processing affect the review pathway.
- Align the review level for potentially contaminated primary cells with the review level that would apply to direct research involving the known or reasonably suspected agent.

CLARIFY BSO RESPONSIBILITY FOR INSTITUTIONAL INSPECTION PROGRAMS

The draft policy requires an institution to appoint a Biological Safety Officer when it conducts research at BSL-3 or BSL-4 or conducts research involving gene drive modified organisms. The draft then identifies "conducting periodic inspections" as one of the BSO's duties, including inspections to ensure that biocontainment facilities and equipment function properly, biosafety standards are followed, and IBC approval conditions are implemented.

The policy should clarify both the scope of the inspection requirement and the nature of the BSO's responsibility. Periodic inspections specifically required under the NIH policy should focus on BSL-3/ABSL-3 and BSL-4/ABSL-4 laboratories, where the policy requires appointment of a BSO and where facility systems, specialized containment equipment, and operational practices warrant formal recurring verification. Institutions may use inspections for BSL-1/ABSL-1 and BSL-2/ABSL-2 research as part of their broader institutional biosafety programs, but the appointment of a BSO should not, by itself, create an additional federal inspection requirement for every lower-containment laboratory.

This distinction is particularly important because some institutions appoint a BSO even when the policy does not require one. Institutions should not be subject to additional federal requirements solely because they voluntarily establish a more comprehensive biosafety program or designate a

BSO to support lower-containment research. Such an outcome could discourage institutions from voluntarily appointing qualified biosafety professionals.

The phrase "conducting periodic inspections" could also be interpreted to require the designated BSO to personally inspect every applicable laboratory. That approach would be impractical for large or geographically distributed institutions and would not necessarily improve inspection quality. Institutions commonly conduct inspections through qualified biosafety, environmental health and safety, research safety, animal safety, infection control, facilities, or other technical personnel working within an established institutional inspection program.

The BSO should retain oversight of the inspection process, including responsibility for establishing appropriate inspection standards, ensuring that inspections are performed by qualified personnel, reviewing significant findings, monitoring corrective actions, and reporting material deficiencies to the IBC and institution. The BSO should not be required to personally conduct each inspection.

The draft already recognizes a comparable delegation model by allowing the IBC's periodic review of approved research to be delegated to the BSO "or other staff, as appropriate." The inspection provisions should provide similar flexibility.

Mass General Brigham recommends the NIH:

- Clarify that the recurring inspection requirement under the policy applies to BSL-3/ABSL-3 and BSL-4/ABSL-4 laboratories.
- Clarify the inspection requirements applicable to research involving GDMOs when that research is conducted below BSL-3/ABSL-3.
- Clarify that the BSO must oversee the institutional inspection process but is not required to personally conduct every inspection.
- Permit qualified biosafety, environmental health and safety, research safety, animal safety, infection control, facilities, or equivalent personnel to conduct inspections under BSO oversight.
- Require the BSO to establish or approve inspection standards, review significant findings, ensure appropriate corrective-action follow-up, and report significant deficiencies to the IBC and institution.
- Avoid imposing additional requirements on institutions solely because they voluntarily appoint a BSO or maintain a biosafety program that exceeds the minimum federal requirements.

SYSTEM-LEVEL BIOSAFETY ASSURANCES FOR INTEGRATED HEALTH SYSTEMS

The draft requires each institution to submit a Biosafety Assurance describing its lines of authority, responsible personnel, biosafety procedures, IBC roster, meeting minutes, incident reports, training, and relevant research activities. The policy does not explain how the

requirement applies when multiple hospitals or legal entities rely on a common IBC, centralized biosafety administration, and shared governance structure.

. Requiring each participating hospital or legal entity to submit a separate Assurance containing the same IBC membership, governance procedures, policies, training systems, public records, and administrative information would create duplicative work without strengthening oversight.

NIH should permit an integrated health system, university system, or similarly structured research organization to submit one system-level Assurance when participating institutions operate under a common IBC and coordinated biosafety governance structure. The Assurance could identify each covered component institution and describe any institution-specific officials, BSOs, facilities, responsibilities, or local requirements while incorporating shared program elements once.

A system-level Assurance would provide NIH with a more accurate description of how an integrated biosafety program operates. It would also support consistent oversight across participating institutions while preserving accountability for institution-specific responsibilities.

Mass General Brigham recommends the NIH:

- Permit a single system-level Biosafety Assurance for an integrated health system or research organization operating a common IBC and centralized biosafety governance structure.
- Permit multiple hospitals, research institutions, and legal entities to be listed as component institutions under the system-level Assurance.
- Clarify which Authorized Organizational Representative may submit and certify the system-level Assurance.
- Replace “continuously updated” with a defined period for reporting material changes.
- Distinguish material changes requiring NIH notification from routine administrative updates maintained in institutional records or on public websites.

RETAIN ESTABLISHED EXEMPTIONS AND CREATE A MECHANISM FOR FUTURE EXCLUSIONS

The draft policy substantially expands federal biosafety oversight beyond research involving recombinant or synthetic nucleic acid molecules, but it does not include a dedicated section identifying research that is excluded from the policy. It also does not preserve the exemptions developed under Section III-F and Appendix C of the current NIH Guidelines.

The current exemptions incorporate decades of experience and risk-based determinations of research activities that do not present a significant risk to human health or the environment. Unless NIH has identified new evidence that an existing exemption no longer provides adequate protection, the exemption should be carried forward into the final policy.

The need to retain existing exemptions is particularly important because the draft policy broadly covers genetically modified cells, viruses, and organisms. Without an explicit exclusions section, routine activities involving well-characterized host-vector systems, established cell lines, transgenic rodents, and other commonly used research systems could require IBC approval even though the same activities are currently exempt from the NIH Guidelines.

The final policy should therefore include a dedicated "Exclusions" section that retains, at a minimum, the following existing exemptions should be included:

- Cells, viruses, or organisms genetically modified exclusively through the introduction of genetic material derived from the same species, when the resulting genetic material can occur through natural physiological processes.
- Prokaryotic organisms genetically modified with sequences consisting entirely of DNA from the same prokaryotic host, including its plasmids or viruses, when the genetic material is propagated only in that host or transferred to another host through well-established physiological processes.
- Eukaryotic cells or organisms genetically modified with sequences consisting entirely of DNA from the same eukaryotic host, including DNA derived from its mitochondria or plasmids, when the genetic material is propagated only in that host or in a closely related strain of the same species.
- Cells or organisms genetically modified through the exchange of DNA between species that are known to exchange DNA through well-established physiological processes.
- Well Characterized tissue-culture cells genetically modified with recombinant or synthetic nucleic acid molecules, provided that the modification does not introduce or produce an infectious biological agent, biological toxin, gene-drive system, or other biological hazard covered by the policy.
- *Escherichia coli* K-12 strains genetically modified using NIH-certified K-12 host-vector systems, provided that the host-vector system and introduced sequences satisfy the conditions of the applicable exemption.
- *Saccharomyces cerevisiae* and *Saccharomyces uvarum* strains genetically modified using NIH-certified *Saccharomyces* host-vector systems, provided that the host-vector system and introduced sequences satisfy the conditions of the applicable exemption.
- *Bacillus subtilis* or *Bacillus licheniformis* strains genetically modified using characterized host-vector systems, provided that the strains do not revert to a spore-forming phenotype and satisfy the conditions of the applicable exemption.
- Gram-positive organisms genetically modified using specified naturally occurring extrachromosomal elements, provided that the elements are maintained in their natural hosts or transferred to another host through well-established physiological processes and the applicable conditions of the current exemption are satisfied.
- Transgenic rodents purchased or transferred for research purposes, provided that the animals contain no genetic modification derived from a Risk Group 3, Risk Group 4,

restricted, or otherwise covered higher-risk biological agent and otherwise satisfy the conditions of the current exemption.

- Rodents produced through the breeding of two transgenic strains, or through the breeding of a transgenic strain with a wild-type strain, provided that the resulting animals can be maintained under ABSL-1 containment and the breeding does not create a novel or increased biosafety risk.

NIH should also consider extending the exclusions to established low-risk model organisms and laboratory strains, including *Caenorhabditis elegans*, *Drosophila melanogaster*, and *Escherichia coli* B21, when the modification does not introduce a biological agent, toxin, gene-drive system, increased pathogenicity, increased transmissibility, or another identifiable biosafety hazard. These organisms and strains have long histories of research use and may present risks comparable to or lower than transgenic rodents already addressed through the current exemptions.

The final policy should distinguish federal exclusions from institutional discretion. An activity excluded from the federal policy may remain subject to institutional review or applicable state or local requirements. However, an institution's decision to review excluded research should not make the activity subject to federal Biosafety Assurance, public-minutes, federal incident-reporting, or enforcement requirements.

The exclusions section should also retain a general mechanism through which NIH may add, modify, or withdraw exclusions as scientific knowledge and research technologies evolve. The current NIH Guidelines permit NIH to determine, following appropriate notice and opportunity for public comment, that classes of experiments do not present a significant risk to health or the environment. The broader scope of the proposed policy makes such a mechanism even more important. Without it, well-characterized and demonstrably minimal-risk activities could remain subject to federal approval, reporting, public-disclosure, recordkeeping, and enforcement requirements merely because they were not anticipated when the final policy was issued.

Mass General Brigham recommends the NIH:

- Add a dedicated "Exclusions" section to the final policy.
- Retain the existing exemptions in Section III-F and Appendix C of the current NIH Guidelines unless NIH identifies a specific, evidence-based reason to modify or withdraw an exemption.
- Preserve the existing certified host-vector system exemptions, tissue-culture exemptions, and qualifying transgenic-rodent purchase, transfer, and breeding exemptions.
- Consider excluding established low-risk model organisms, including *Caenorhabditis elegans* and *Drosophila melanogaster*, when the modification does not introduce an identifiable biosafety hazard.

- Establish a formal, transparent mechanism for adding, modifying, or withdrawing exclusions based on accumulated experience, scientific evidence, and technological development.
- Permit institutions, professional organizations, and other interested parties to request evaluation of a category of research for exclusion.
- Publish exclusion and equivalency determinations in a centralized, searchable repository that institutions may rely upon.

CLARIFY THE REQUIREMENT TO REPORT DELEGATED APPROVALS "IN FULL" IN PUBLIC MINUTES

Section IV-3 permits an individual IBC member or subgroup of IBC members to review and approve minor amendments and specified categories of lower-risk research. The draft then requires the IBC to be notified when a delegated approval is granted and requires the approval to be "reported in full" at the next scheduled IBC meeting for inclusion in the minutes.

The phrase "reported in full" is not defined. It is unclear whether NIH intends the minutes to include a complete protocol summary and risk assessment for every delegated approval or whether a structured listing of the approval would satisfy the requirement. This ambiguity is particularly significant because the draft minutes template confirms that IBC minutes must be posted on a public-facing institutional website.

Mass General Brigham already presents administrative approvals to the IBC for comment and questions. For example, meeting minutes document presentation of the month's administrative approvals as part of other committee business. The final policy should preserve institutional flexibility to use this type of consent-agenda or summary process.

Requiring protocol-level documentation for every delegated approval would substantially reduce the operational value of delegated review. Institutions may process a large number of lower-risk registrations and minor amendments through delegated pathways. Preparing full public summaries of every delegated action would increase staff workload, lengthen meeting materials and minutes, and require additional review for confidential, proprietary, privacy-sensitive, or security-sensitive information.

The requirement could also blur the distinction between delegated and full committee review. Delegated review is intended to provide a proportionate and efficient pathway for minor amendments and defined categories of lower-risk research. If every delegated approval must subsequently be presented and documented at the same level of detail as research reviewed by the convened committee, much of the efficiency gained through delegated review would be lost.

The final policy should require sufficient information for the IBC and the public to understand the nature and volume of delegated actions without requiring protocol-level disclosure. A structured listing or consent agenda could identify the institutional registration number, general

category of research, type of action, type of biological material, containment level, approval date, and any material conditions. The IBC should retain the ability to request additional information or refer an item for discussion when warranted.

Minor amendments also require separate consideration. Administrative changes such as additions or removals of personnel, changes in contact information, corrections, or other changes that do not affect the risk assessment should not require individual reporting in public minutes. NIH should distinguish administrative updates from scientific amendments approved through delegated review.

Mass General Brigham recommends the NIH:

- Define what information must be included for a delegated approval to be "reported in full."
- Clarify that a structured list, consent agenda, or attached report may satisfy the reporting requirement.
- Permit institutions to report each delegated approval using the institutional registration number, general research category, type of submission or amendment, broad biological materials, containment level, approval date, and material conditions.
- Clarify that reporting a delegated approval does not require the convened IBC to reconsider, ratify, or vote on the approval unless the IBC determines that additional review is warranted.
- Permit the IBC to request additional information or elevate delegated approval for discussion when necessary.
- Exclude purely administrative updates that do not affect the biosafety risk assessment from individual reporting in public minutes.
- Revise "reported in full" to "reported to the IBC through a structured summary sufficient to document the delegated action."

LIMIT THE POLICY'S TOXIN DEFINITION TO TOXINS WITH AN LD50 BELOW 100 NANOGRAMS PER KILOGRAM

The draft policy defines a toxin broadly as "a protein or peptide produced by living organisms that causes harm in humans." Section II includes toxins within the scope of the policy without establishing a potency threshold. Section IV-3 then permits delegated review of biological toxin proteins that are not on the Select Agent list. This language could bring nearly any harmful protein or peptide within federal IBC oversight, regardless of its toxicity, quantity, concentration, route of exposure, or realistic potential to cause harm under laboratory conditions.

The absence of a potency threshold is inconsistent with the risk-based approach NIH has applied under the current NIH Guidelines. Section III-B-1 uses an LD50 of less than 100 nanograms per kilogram body weight to identify genes encoding exceptionally potent toxin molecules.

Examples include genes encoding botulinum toxins, tetanus toxin, diphtheria toxin, and *Shigella dysenteriae* neurotoxin.

This established threshold provides an objective and familiar boundary for identifying toxins of sufficient potency to warrant specialized federal biosafety oversight. Retaining the threshold would also avoid extending the policy to the large number of ordinary proteins and peptides that can cause harm at sufficiently high doses but do not present the type of biosafety risk that warrants federal IBC regulation.

The NIH should therefore retain the established LD50 threshold of less than 100 nanograms per kilogram to identify exceptionally potent toxins and genes encoding exceptionally potent toxins that warrant heightened federal oversight. Toxins above that threshold should be excluded from federal IBC oversight or assigned to delegated review according to potency, quantity, concentration, route of exposure, physical form, and the proposed manipulation.

Mass General Brigham recommends the NIH:

- Retain the established threshold of a human LD50 of less than 100 nanograms per kilogram body weight.

PLANT-DERIVED TOXINS AND TOXIN-PRODUCING PLANT CELLS

The draft policy defines a toxin as a protein or peptide produced by a living organism that causes harm in humans. Although plants are excluded from the genetic-modification components of the policy's scope, the toxin definition does not expressly exclude proteins or peptides produced by plants.

NIH should separately clarify the status of:

1. Purified plant-derived protein or peptide toxins.
2. Intact plants that produce toxins.
3. Plant tissues and plant cell cultures that produce toxins.
4. Genetically modified plant cells engineered to express toxins.
5. Nonprotein and nonpeptide toxic compounds produced by plants.

The final policy should explain whether research with plant cells producing a covered toxin constitutes research with a toxin, research involving an excluded plant, or both.

TOXIC PEPTIDES AND "BIOLOGICAL TOXIN PROTEINS"

The draft definition of toxin includes both proteins and peptides. Section IV-3, however, permits delegated review only for "biological toxin proteins" not on the Select Agent list. Read literally, a non-Select Agent toxic peptide may require full committee review solely because the delegated category refers only to proteins.

If NIH intends delegated review to be available for both categories, Section IV-3 should state:

"Toxins not on the Select Agent list."

Review level should reflect the actual risk, including potency, quantity, concentration, physical form, route of exposure, aerosol potential, experimental manipulation, and capacity for intracellular access, rather than whether the toxin is categorized as a protein or peptide.

GRANDFATHERING AND IMPLEMENTATION

The draft policy would become effective six months after publication and would apply to ongoing and new research. The draft does not clearly explain how existing approvals will transition to the new framework.

Mass General Brigham recommends the NIH:

- Allow existing IBC approvals to remain valid through their current expiration dates.
- Avoid requiring institutions to conduct de novo review of their entire active portfolio within the implementation period.
- Phase in the Biosafety Assurance, review-cycle changes, registration conversion, reporting systems, and public-disclosure requirements.
- Publish final templates, definitions, reporting criteria, technical specifications, and implementation guidance before the transition period begins.
- Provide sufficient time for institutions to modify electronic systems, policies, forms, training, websites, and reliance arrangements.
- Establish a corrective-action period before imposing institution-level enforcement for implementation-related deficiencies.

DEFINITION AND CONSISTENT USE OF GDMO

The draft uses "GDMO," "gene drive modified organism," and "gene drive modified biological agent" without clearly establishing whether these terms are synonymous. The distinction is important because "organism" and "biological agent" may not have identical meanings under the draft definitions.

NIH should define GDMO at its first use and in the general definitions and use one term consistently throughout the policy. The definition should clarify whether the category includes animals, arthropods, microorganisms, viruses, cells, and other biological systems. It should also clarify whether the definition requires a functional gene drive or includes organisms used to develop, test, or contain individual gene-drive components.

CLARIFY AND STREAMLINE NIH REVIEW OF EMERGING, NOVEL, AND ZOONOTIC AGENTS

Section IV-1 requires NIH and IBC approval before initiation of research involving an emerging, novel, or zoonotic agent when neither a Risk Group classification nor a recommendation for minimum containment is available in the BMBL. The IBC must petition NIH for a determination of the minimum containment level and may not approve the research until NIH and other applicable authorities authorize it. The request must include a detailed description of the agent, modifications, biological systems, experimental manipulations, reagents, proposed containment, institutional risk assessment, and supporting data.

Mass General Brigham supports federal oversight when an agent presents substantial uncertainty that cannot be resolved through an institutional risk assessment. However, the proposed requirement is broad and could delay research involving an agent that is absent from the BMBL for reasons unrelated to elevated risk. The BMBL does not provide a Risk Group classification or minimum containment recommendation for every known microorganism, recently identified agent, zoonotic agent, attenuated strain, or novel construct.

"Zoonotic" is not inherently synonymous with high risk or high uncertainty. An agent may be capable of animal-to-human transmission and still present a well-characterized or limited risk. Similarly, an emerging agent may be newly identified but closely related to a known agent with an established Risk Group and containment recommendation. Mandatory NIH review should depend on the degree of uncertainty and potential severity of the agent, not solely on whether the agent is categorized as emerging, novel, or zoonotic. As an example, our research portfolio includes research on *Arcanobacterium* pyogenes, a zoonotic agent not covered by the BMBL. Thus our research would not continue upon adoption of the policy while the NIH or the CDC makes a determination on this agent.

The current NIH risk-assessment framework recognizes that unlisted agents may be assessed using their known and potential properties, their relationship to listed agents, and experiment-specific factors including pathogenicity, infectious dose, environmental stability, route of spread, communicability, quantity, available countermeasures, and proposed manipulations. The new policy should preserve a meaningful role for institutional risk assessment rather than requiring NIH review whenever an agent is not specifically listed in the BMBL.

When NIH review is required, the policy should permit an institution to approve work at a conservatively selected containment level while the federal determination is pending. An IBC may be able to determine that an unclassified agent can be safely handled at a containment level equal to or greater than that used for a closely related agent. Prohibiting all work during NIH review may delay time-sensitive diagnostic, surveillance, public-health, or emerging-infectious-disease research without improving safety.

NIH should also establish a process for publishing and reusing its determinations. The draft requires NIH to publish approved lower-containment determinations for RG3 and RG4 agents,

but it is less explicit about publishing all determinations for emerging, novel, or zoonotic agents. NIH should maintain a searchable repository that institutions may rely upon when proposed work involves the same agent or a materially equivalent agent, construct, attenuation, and experimental procedure.

Finally, NIH determinations should not remain indefinitely separate from the BMBL or other authoritative federal classifications. When CDC, NIH, the BMBL, the Federal Select Agent Program, or another appropriate federal source subsequently assigns a Risk Group or minimum containment recommendation, NIH should review, update, or retire its earlier determination. This will prevent conflicting classifications and unnecessary repeated federal petitions.

Mass General Brigham recommends the NIH:

- Define "emerging," "novel," and "zoonotic" using objective and risk-based criteria.
- Clarify that classification as emerging, novel, or zoonotic does not, by itself, establish that an agent presents elevated risk requiring federal review.
- Limit mandatory NIH review to agents for which the absence of an established classification creates material uncertainty regarding appropriate containment or presents the potential for serious human, community, or environmental harm.
- Permit IBCs to assign containment without prior NIH approval when adequate information exists to support a documented risk assessment using a closely related agent, published evidence, or other authoritative information.
- Permit institutions to initiate research at conservatively selected containment while NIH review is pending, unless NIH identifies a specific reason the research should not proceed.
- Establish target timelines for NIH acknowledgment, completeness review, requests for additional information, and final determination.
- Develop a streamlined review pathway for an agent that is closely related to an agent with an established Risk Group or BMBL containment recommendation.
- Publish all NIH determinations involving emerging, novel, or zoonotic agents in a public, searchable repository.
- Permit institutions to rely on a prior NIH determination involving the same or a materially equivalent agent, construct, attenuation, and experimental activity.
- Coordinate determinations with CDC and other relevant federal agencies to reduce duplicative review.
- Establish a process to review, update, supersede, or retire an NIH determination when the BMBL or another authoritative federal source subsequently assigns a Risk Group or minimum containment recommendation.

CLINICAL-RESEARCH COVERAGE

The draft policy identifies categories of clinical research requiring IBC review, including products capable of shedding, replicating, or integrating, products involving higher-risk manipulations, and deliberate administration of RG2 or higher wild-type agents.

Mass General Brigham recommends the NIH:

- Whether "capable of shedding, replicating, or integrating" refers to the final administered product, residual manufacturing components, or the original method used to manufacture or modify the product.
- The meaning of "higher-risk manipulation."

The final policy should also distinguish federally required clinical oversight from broader clinical research that an institution elects to review under institutional or local authority.

CONCLUSION

Mass General Brigham supports NIH's effort to modernize biosafety oversight and agrees that the final policy should establish a comprehensive, transparent, accountable, and risk-based framework for research involving biohazards. Many elements of the proposed framework are consistent with the broad institutional biosafety oversight that Mass General Brigham already provides. However, several provisions require clarification or revision to ensure that the final policy advances biosafety without discouraging incident reporting, interrupting compliant research, requiring repetitive review of unchanged activities, or imposing federal requirements that are disproportionate to the risks presented.

Our highest priority recommendation is that NIH remove the requirement for institutions to publicly post individual incident reports. Effective biosafety programs depend on prompt reporting, candid investigation, and meaningful analysis of contributing factors. Public disclosure of event-specific reports may discourage personnel from reporting minor incidents, suspected exposures, and near misses and may permit identification of affected individuals even when direct identifiers are removed. NIH can more effectively advance transparency and shared learning through aggregated, deidentified incident analyses and annual national summaries.

Our second highest priority is replacing mandatory three-year de novo review with a risk-based renewal framework. This requirement would likely have the greatest operational impact on the institutional biosafety program and would require substantial new resources from investigators, biosafety officers, IBC staff, committee members, and institutional leadership. Much of the additional effort would be directed toward reconstructing and rereviewing registrations for research that has not materially changed. Permitting approvals of up to five years, supported by annual investigator certification, prospective review of risk-relevant changes, and delegated renewal of unchanged research, would maintain rigorous continuing oversight while allowing

institutional resources to remain focused on new research, substantive amendments, higher-risk activities, incident response, inspections, training, and other work that directly advances biosafety.

Mass General Brigham appreciates NIH's consideration of these comments and welcomes continued engagement with NIH as the final policy and implementation materials are developed. If you have any questions, please contact Aimee Kasenga, Director of Public Policy, Office of Government Affairs, at akasenga@mgb.org. Thank you for this opportunity to provide feedback.

Name:

Name of Organization:

Type of Organization: Non-Profit Research Organization

Role: Investigator/Researcher

Date Submitted: 10/12/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed expansion of biosafety oversight should be guided by scientifically justified, evidence-based risk assessments rather than broad definitions that unnecessarily capture routine, low-risk research. For laboratories working with primary human cells, genetically modified cell lines, transgenic animals, viral vectors, and infectious agents, an overly expansive or ambiguous definition of biohazards could result in inconsistent institutional interpretations, duplicative IBC reviews, and unnecessary delays. NIH should clearly distinguish established biological hazards from hypothetical or negligible risks and establish explicit criteria for determining which activities require formal IBC oversight. The policy should also clarify the boundaries between IBC, IACUC, and other institutional oversight responsibilities to avoid regulatory gaps or overlapping requirements. Importantly, investigators should not be held personally accountable for institutional failures to interpret, implement, or enforce biosafety requirements, particularly when they lack authority over institutional infrastructure or administrative decisions. NIH should ensure that expanded oversight is proportional to demonstrable risk, consistently implemented across institutions, and supported by clear guidance that protects both research safety and investigators' ability to conduct science.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support a tiered, risk-based approach to biosafety oversight, provided that risk classifications are scientifically justified, clearly defined, and consistently applied across institutions. NIH should establish uniform federal criteria for risk assessment and oversight requirements, while allowing local IBCs to evaluate institution-specific conditions without imposing additional restrictions unsupported by demonstrable biological risks. Excessive local discretion may lead to inconsistent interpretations, unnecessary protocol reviews, prolonged approval timelines, and administrative requirements that vary substantially between institutions. Importantly, institutions should remain accountable for biosafety infrastructure, regulatory interpretation, and timely review processes rather than transferring these responsibilities and associated liabilities to Principal Investigators. Investigators should not face research delays, missed grant milestones, funding consequences, or professional and legal exposure resulting from inconsistent institutional decisions or administrative failures beyond their control. NIH should establish clear mechanisms for resolving disagreements between investigators and institutional oversight committees,

including access to authoritative federal guidance. Effective tiered oversight should ensure that higher-risk research receives appropriate scrutiny while low-risk research proceeds efficiently, without compromising safety or unnecessarily obstructing scientific progress.

3. Continued utility of Risk Groups: Risk Groups (RGs) should remain a useful starting point for biosafety assessment, but they should not independently determine containment requirements, particularly when biological agents are genetically modified. Genetic modifications may alter pathogenicity, host range, transmissibility, or other characteristics relevant to biological risk. Conversely, not all genetic modifications increase risk, and additional containment requirements should not be imposed solely because an agent has been genetically modified. NIH should adopt an evidence-based framework that considers the properties of the modified agent, the experimental procedures, potential exposure routes, and available safeguards when determining appropriate Biosafety Levels (BSLs), consistent with the principles outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL). NIH should establish clear, standardized federal guidance to minimize inconsistent interpretations among institutional biosafety committees and prevent unnecessary restrictions on routine research involving viral vectors, genetically modified cells, and transgenic animals. Institutions should remain responsible for applying these standards consistently, providing appropriate biosafety infrastructure, and resolving regulatory ambiguities rather than transferring these responsibilities and associated risks to Principal Investigators. The objective should be to ensure that biosafety requirements reflect actual experimental risks while enabling research to proceed safely and without avoidable administrative delays.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary compliance among institutions not subject to the proposed biosafety policy by providing clear, accessible, and standardized guidance, training resources, and technical assistance rather than creating additional administrative or regulatory burdens. Voluntary participation should be supported through institutional capacity building, including access to biosafety expertise, risk assessment tools, and established best practices. Importantly, NIH should distinguish between institutional responsibilities and those of individual investigators, ensuring that voluntary compliance does not result in institutions transferring additional administrative obligations, financial costs, or legal liabilities to Principal Investigators. Institutions choosing to adopt the policy should be responsible for providing the necessary infrastructure, qualified personnel, and oversight mechanisms. NIH should also establish clear boundaries between voluntary best practices and mandatory requirements to prevent inconsistent institutional interpretations or the gradual conversion of voluntary recommendations into de facto obligations. The objective should be to promote a consistent culture of biosafety across the research community while preserving institutional accountability, proportionality of oversight, and investigators' ability to conduct research without unnecessary administrative barriers or professional risks.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed Incident Reporting and IBC Meeting Minutes Templates should prioritize biosafety accountability while protecting investigators from unnecessary professional, legal, and financial risks. NIH should clearly distinguish institutional compliance failures, equipment or infrastructure deficiencies, and administrative errors from actions directly attributable to investigators. Incident reports should document the circumstances, contributing factors, corrective actions, and institutional responsibilities without automatically assigning blame to PIs. Publicly accessible reports and meeting minutes should exclude personally identifiable information, unpublished scientific discoveries, proprietary methodologies, patentable inventions, and

other confidential research details that are not essential to public safety. NIH should require institutional review of reports for accuracy and confidentiality, with opportunities for affected investigators to identify factual errors or sensitive information before public disclosure, without delaying mandatory reporting. Investigators should not face reputational damage, funding consequences, or personal legal expenses resulting from institutional failures or inappropriate disclosure of confidential information. NIH should also establish clear procedures for correcting inaccurate public records and responding to confidentiality breaches, including appropriate legal assistance and remediation. Ultimately, reporting should promote transparency, institutional accountability, and improvements in biosafety practices without creating unnecessary administrative burdens or exposing investigators to avoidable risks.

6. Other feedback relevant to this resource: Successful implementation of the proposed biosafety policy will require comprehensive, timely, and standardized training of NIH personnel, institutional biosafety officers, IBC members, and research administrators before the policy takes effect. A significant concern is the lag between NIH policy changes and the availability of clear, authoritative guidance, which creates inconsistent interpretations that propagate throughout research institutions and ultimately place unnecessary administrative burdens and risks on Principal Investigators. NIH should provide practical implementation resources, including standardized risk assessment criteria, clear distinctions between institutional and investigator responsibilities, guidance on coordinating IBC and IACUC approvals, and explicit procedures for resolving regulatory ambiguities. Dedicated communication channels between NIH and institutional compliance offices should ensure that institutions receive consistent instructions without transferring responsibility for interpreting policies to investigators. NIH should also establish reasonable review timelines, escalation mechanisms for administrative delays, and safeguards protecting investigators from professional, financial, or legal consequences arising from institutional compliance failures beyond their control. Implementation resources should include clear procedures for protecting confidential research information and addressing unauthorized disclosures. Most importantly, NIH should evaluate institutional readiness and staff competency before implementation rather than relying on investigators to resolve deficiencies in administrative systems. The ultimate objective should be to enable safe and timely scientific research while ensuring that institutions and NIH personnel remain accountable for their respective responsibilities.

Description: PDF comment on the proposed policy on behalf of the Campus Safety Health and Environmental Management Association, the premier association for environmental health and safety leadership in higher education. CSHEMA represents institutions that range from large research-intensive universities with mature biosafety programs to smaller colleges that may have limited or no dedicated biosafety staff. Our members include biosafety professionals, environmental health and safety practitioners, and institutional leaders responsible for implementing biosafety requirements across diverse research and teaching environments.

Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards

Response to NOT-OD-26-112

October 12, 2026

Submitted Electronically

The Campus Safety, Health, and Environmental Management Association (CSHEMA) is the premier association for environmental health and safety leadership in higher education. CSHEMA represents institutions that range from large research-intensive universities with mature biosafety programs to smaller colleges that may have limited or no dedicated biosafety staff. Our members include biosafety professionals, environmental health and safety practitioners, and institutional leaders responsible for implementing biosafety requirements across diverse research and teaching environments.

CSHEMA appreciates NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions. **Due to such uncertainty in the final requirements, CSHEMA encourages NIH to provide an opportunity for public review and comment on the next draft before it is finalized.**

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." The policy should clarify whether precautionary post exposure prophylactic treatment is considered "agent-specific treatment". It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

6. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

CSHEMA recommends that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

Conclusion

CSHEMA supports NIH's goal of modernizing biosafety oversight and appreciates the draft's movement toward broader risk awareness, clearer incident thresholds, delegated review, and national safety learning. For the policy to succeed, however, modernization must strengthen the institutional systems that perform biosafety work rather than simply expand their obligations.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified

local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

CSHEMA respectfully requests that NIH revise the draft consistent with these recommendations, release complete implementation materials for public review, pilot key templates and processes, and provide a minimum 24-month phased implementation period. CSHEMA welcomes continued engagement and would be pleased to assist NIH in testing implementation resources or gathering additional institutional perspectives.

Sincerely,

Robin Izzo
President
Campus Safety, Health, and Environmental Management Association

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Re: NOT-OD-26-112

To Whom It May Concern,

The University of Mississippi Medical Center (UMMC) supports NIH's goal of providing consistent biosafety oversight proportionate to research risk. The proposed policy, however, contains conflicting instructions about the research it covers, the approvals needed to begin work, and the incidents that must be reported. Institutions need a single, consistent answer to each of these questions before the policy becomes effective. We request amendments to the provisions identified below, followed by a phased implementation period that permits institutions to revise their procedures and systems.

Conflicting requirements that need amendment

1. Section II scope and Section III incident reporting

Section II defines covered research through two cumulative requirements: a known or potential risk to human health AND involvement of at least one of four enumerated categories. Both conditions must be satisfied. Neither potential human-health risk alone nor the presence of an enumerated material alone establishes coverage. NIH funding and a laboratory's BSL/ABSL designation do not independently satisfy this definition.

Section III-B does not consistently preserve that boundary. Its general incident-review provision applies to research subject to the Policy, and its animal-incident bullet repeats that qualification. The adjacent first-aid bullet instead refers to any incident at BSL-1/ABSL-1 or BSL-2/ABSL-2 when first aid is administered without requiring that the research satisfy Section II. Read literally, the unqualified first-aid provision would require IBC review and public reporting of a minor injury even when the study involves none of Section II's four categories. The injury could demonstrate human-health risk, but it would not establish involvement of an enumerated material. The incident provision therefore states a broader trigger than the scope provision. Other language limiting review to covered research does not remove the need to reconcile these instructions.

Requested correction: State expressly that the incident review, reporting, and publication requirements apply only when the underlying research satisfies BOTH Section II conditions. Apply that qualification consistently throughout Section III and the required templates.

2. Other federal agency oversight and mandatory IBC approval

Section II says covered research that is also under another federal agency's regulation or purview may proceed under that agency's oversight once its approvals or clearances have been obtained. Section III-C, however, prohibits covered research from proceeding without IBC or delegated approval, and Section IV-2 specifically prohibits initiation of clinical research until IBC and other applicable approvals are obtained.

For a clinical study authorized by FDA, Section II provides apparent permission to proceed while Sections III-C and IV-2 require an additional approval. The draft does not state whether the other-agency provision is an exception to the later requirements or merely an additional condition.

Requested correction: State whether other-agency authorization supplements or substitutes for NIH and IBC oversight. If it supplements that oversight, revise Section II to require all applicable approvals before initiation. If it substitutes, identify the requirements displaced and add the corresponding exception to Sections III and IV.

THE UNIVERSITY OF MISSISSIPPI MEDICAL CENTER
EDUCATION · RESEARCH · HEALTHCARE

Office of Associate Vice Chancellor for Research
2500 North State Street, Jackson MS 39216
Phone: 601-815-2681

3. The laboratory setting definition and covered clinical research

Section II confines the policy to biomedical research in laboratory settings and defines laboratory research as research conducted within BSL/ABSL 1–4 containment facilities. Section IV-2 nevertheless requires IBC review of specified clinical administrations, and Section V-E expressly recognizes that clinical administration commonly occurs in settings that do not conform to laboratory BSLs. The definition therefore does not consistently encompass a setting that the operative provisions expressly regulate.

Requested correction: Revise Section II to include the clinical activities and settings NIH intends to cover, including those outside designated BSL/ABSL facilities. Specify how incident-reporting categories organized around BSL/ABSL levels apply in those clinical settings.

4. Overlapping NIH reportable and local only incident categories

Section III-B requires NIH reporting of BSL-2/ABSL-2 exposures that require agent-specific treatment beyond basic first aid. Its subsequent category of incidents that do not require NIH reporting includes any animal incident during covered research at BSL-1/ABSL-1 or BSL-2/ABSL-2, with bites and scratches among the examples.

An ABSL-2 animal bite involving a deliberately studied agent and requiring agent-specific treatment beyond first aid satisfies both descriptions. One provision requires NIH reporting; the other places the same event in a category described as not requiring it. This conflict persists even when the research clearly satisfies Section II.

Requested correction: Harmonize the reporting requirements and remove the reporting requirement for minor injuries that do not represent a contagious infection risk. Apply the same precedence rule to the template so an institution can assign an incident to one reporting pathway consistently.

5. The incident template requires submission of reports the policy excludes

Section III-B requires the incident template for public reports, including reports that do not require submission to NIH. Yet the Draft NIH Incident Reporting Template, page 1, states: “Completed reports must be sent to NIH.” Page 2 of the template itself recognizes that only some reports require NIH submission. An institution completing a local-only report therefore receives incompatible submission instructions.

Requested correction: Replace the unconditional instruction with a direction to submit reports to NIH only when Section III-B requires submission. Add a field distinguishing NIH-reportable incidents from those requiring institutional review and public posting only. Make that distinction consistent across the policy, instructions, and report fields.

<u>Implementation burden and compliance guidance</u>

6. Transition for existing research

Section II would apply the policy to ongoing NIH-supported work and otherwise covered non-NIH-funded work at NIH-funded institutions six months after publication. Section III-A also requires an NIH-approved Biosafety Assurance before covered research may proceed. Institutions will need to identify newly covered

Office of Associate Vice Chancellor for Research
2500 North State Street, Jackson MS 39216
Phone: 601-815-2681

projects, obtain reviews, revise electronic records and reporting routes, and train investigators and reviewers. NIH's own Assurance-review capacity will affect whether institutions can meet the deadline.

Please establish a phased transition for ongoing work, explain how existing IBC approvals will carry forward, and provide a transition mechanism for institutions with timely submitted Assurances awaiting NIH action. The implementation period should begin only after the final templates and operational guidance are available. NIH should assess the workload created by institution-wide coverage regardless of a project's funding source and consider limiting the requirements only to NIH-funded research.

7. Proportionate review and documentation

Section III-B calls for a de novo registration and review at intervals no longer than three years. We suggest a process for a focused renewal for unchanged protocols, with a current assessment of materials, procedures, containment, personnel, and relevant incidents. Require a complete resubmission only when changes warrant it. This would preserve reassessment without routinely recreating information already held by the institution.

We support the delegated-review mechanism in Section IV-3. NIH should provide criteria for minor amendments and standardized review of recurring low-risk activities. The required minutes template already allows delegated approvals to be recorded as a list; the final policy should clearly preserve that option. Equivalent institutional minutes formats should also be acceptable when they capture the required decisions and rationale.

Sections III-A and III-C assign training duties to institutions and PIs, and Section III-B requires periodic review of approved research. Please identify the minimum training content, acceptable documentation, and expectations for periodic review. Existing training and inspection programs should satisfy these duties when they address the applicable requirements. NIH should provide example IBC application questions addressing the biohazard, experimental procedures, and any genetic modifications. The amount of detail required should reflect the risks and complexity of the proposed work.

8. Incident workflows records and public disclosure

IBC review, NIH notification, and public posting create distinct institutional tasks. Please allow initial incident reporting through existing safety or occupational-health channels, with timely referral for required IBC review and NIH notification. Identify which incident reviews may be delegated and how those reviews must be recorded. For minor administrative lapses and low-risk incidents, NIH should adopt reporting and documentation requirements proportionate to the event's consequences and corrective action.

Section III-A requires at least five years of public access to minutes and incident reports, while some underlying award records must be retained longer. Please provide a retention schedule that addresses public copies, underlying records, records linked to multiple awards, and research without a federal award. Institutions need those specifications to configure and validate their record systems.

The expanded public-posting duties also require staff time for preparation, review, and redaction. Please identify the information that must appear publicly and permit a separate complete institutional record. Redaction guidance should address personnel privacy and the security implications of disclosing animal facilities, operational details, and related information across multiple public documents. The final guidance should explain how to report medical response and corrective action without identifying affected personnel.

9. Definitions needed to apply the requirements consistently

Two provisions in Section IV-2 need operational definitions. Primary cells that may contain adventitious agents could encompass a very broad range of specimens without a criterion for credible contamination risk. NIH should specify how cell source, screening, and planned manipulations determine the review requirement. Similarly, the examples of higher-risk clinical manipulations do not establish a decision rule. NIH should identify the relevant product and procedure characteristics and provide examples on both sides of the threshold.

We disagree with defining transient expression from non-integrating, non-replicating mRNA as genetic modification solely because the mRNA can be translated. Section II's definition conflates introduction of a template for temporary protein production with alteration of the recipient's genome. NIH should distinguish these processes explicitly and revise the definition so that non-integrating, non-replicating mRNA that produces transient protein expression without inducing stable genomic changes is not classified as genetic modification merely because it is translated.

This distinction should not exclude mRNA used to induce stable genomic changes, such as delivery of a gene-editing enzyme. Nor would it prevent biosafety oversight when the research otherwise satisfies both Section II conditions, for example through expression of a covered toxin. Risks associated with an encoded product, its delivery, or experimental exposure should be assessed on their own merits.

10. Implementation at rural and community research sites

Our institution serves a largely rural state. NIH should assess whether the proposed implementation requirements could reduce rural access to covered research. Where covered studies are conducted through geographically dispersed hospitals and clinics, uncertainty about clinical settings and oversight responsibilities could encourage institutions to concentrate those studies at a central academic campus. That could increase travel burdens for rural participants. NIH should clarify how covered research can be conducted safely in community settings without unnecessary duplication of oversight.

The final policy should expressly describe how a central or externally administered IBC may oversee covered work at satellite and affiliated sites. It should distinguish a participating location from a separate institution and specify who must hold a Biosafety Assurance, review incidents, maintain records, and post reports. Shared training, records, and oversight should be permitted when they satisfy the applicable requirements. Assessment of each site should reflect its actual activities and biosafety risks.

A smaller research partner conducting relatively few covered studies could face substantial administrative work per study. The proposed duties do not expressly require every rural clinic to establish its own IBC or obtain a separate Assurance, but unclear allocation of responsibilities could lead institutions to duplicate functions unnecessarily. NIH should provide a framework for shared oversight and reliance arrangements that preserves institutional accountability while making community participation feasible.

The six-month transition also needs to account for coordination across multiple sites and organizations. NIH should provide standardized training and reporting resources and phase in requirements for existing networks after those resources are available. The transition should allow institutions to establish shared procedures and obtain required approvals without unnecessarily interrupting covered research in rural communities.

Phone: 601-815-2681

We request that NIH reconcile the conflicting instructions in the policy and templates before finalization, then provide the definitions and transition arrangements necessary for consistent implementation. Institutions should be able to determine what research is covered, which approvals are required, and where an incident must be reported by applying one coherent set of requirements.

Sincerely,

Gene L. Bidwell, III, Ph.D.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Comments on Section IIIB:
- IIIB: “Any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approvals…” Question: Does NIH really want a report sent if a PI is late to renew their IBC registration? How late is reportable?
- IIIB: Question: If a researcher is collecting blood from a participant and a needlestick happens and the researcher seeks medical attention for the BBP risk, including HIV prophylaxis, would this have to be reported to NIH and publicly posted on the institution’s website?
- IIIB: Comment: I question if mandatory public posting of incidents provides meaningful transparency benefits beyond existing reporting and disclosure mechanisms. I am also concerned that public posting requirements could lead to less reporting of incidents or seeking guidance from biosafety professionals. Principal investigators may become more hesitant to provide research and training opportunities to students, trainees, and less experienced laboratory personnel if publicly posted incidents are perceived as carrying reputational consequences, particularly given the increased likelihood of errors occurring during training and skill development.

6. Other feedback relevant to this resource: '- Section II: Question: Will a timeline and transition period be published? “6 months from publication of final Policy” would be difficult deadline to meeting as electronic protocol applications, training, posting, IBC charters, policies, etc. would have to be changed.

- Section IIIA: Question: Will a template “Assurance” be provided to institutions?

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Definition and Oversight of Toxins

The George Mason University IBC supports NIH's intent to ensure appropriate oversight of biologically derived toxin research. However, the proposed definition of a toxin as "a protein or peptide produced by living organisms that causes harm in humans" is overly broad and may result in inconsistent interpretation and implementation across institutions.

As written, the definition could encompass a wide range of materials with different hazard profiles, including venoms, endotoxins, algal and fungal toxins, commercially available purified toxins, and non-Select Agent toxins below Federal Select Agent Program permissible thresholds.

Operational Impact: Without clearer, risk-based applicability criteria, institutions may reach different conclusions regarding which toxin research activities require IBC review, increasing administrative burden while providing limited additional biosafety or biosecurity benefit.

Recommendation: NIH should consider retaining the existing toxin oversight scope established under the NIH Guidelines until more specific risk-based applicability criteria can be developed. NIH Guidelines Section III-B and Appendix F-I already provide a well-established trigger for NIH/IBC review of experiments for genes encoding toxin molecules with LD50 thresholds. Toxin research is also governed through multiple complementary oversight mechanisms, including Federal Select Agent Program regulations and toxin due diligence programs, as well institutional laboratory-specific risk assessments in accordance with the CDC/NIH Biosafety in Microbiological and Biomedical Laboratories.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

Date Submitted: 10/12/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): George Mason University's Institutional Biosafety Committee supports modernization of the NIH biosafety framework and encourages a final policy that is clear, risk-based, and scalable across institutions with diverse research portfolios. As a growing research university with a strong commitment to student engagement in research and education, our priority is to support the safe, ethical, and compliant conduct of biological research through a framework that is both effective and practical to implement. We encourage NIH to align requirements with demonstrated biosafety and biosecurity risks, preserve institutional flexibility, and provide clear implementation guidance, examples, and transition provisions. We also encourage NIH to consider the cumulative impact of concurrent federal research oversight initiatives and, where possible, harmonize requirements, reporting mechanisms, and implementation timelines. The final policy should strengthen biosafety practices while minimizing duplicative or low-value administrative requirements that could disproportionately impact institutions of varied sizes, missions, and research capacities or divert limited biosafety resources from activities presenting the greatest potential risk.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Name of Organization: George Mason University

Type of Organization: Institutional Research Oversight Committees e.g. IRB

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/12/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Scope of Genetically Modified Organisms

The George Mason University IBC supports NIH's goal of ensuring appropriate oversight of emerging biotechnology and genetically modified organisms. However, the proposed scope provision covering "cells, viruses, or organisms, other than plants, that have been genetically modified" may unintentionally expand IBC oversight to a broad range of routine, low-risk research activities.

As written, the definition of genetic modification includes nucleic acid molecules that "can be transcribed or translated," potentially encompassing common molecular biology tools and models such as expression vectors, reporter constructs, commercially available modified cell lines, transgenic animals, and CRISPR-edited cells with well-characterized risk profiles.

This concern was identified immediately by a Principal Investigator and IBC member during our initial committee review of the draft policy. Investigators routinely evaluate the risks associated with genetic modifications as part of study design and required IBC submissions. The concern is not whether genetically modified materials warrant oversight, but whether oversight should be triggered by the presence of a genetic modification alone, regardless of its impact on biosafety or biosecurity risk.

Operational Impact: A broad interpretation could substantially increase the number of protocols requiring IBC review, lengthen review timelines, and divert limited IBC and biosafety resources from higher-risk activities, including new high-consequence life sciences research oversight requirements by our Institutional Review Entity.

Recommendation: NIH should clarify whether oversight is intended to be triggered by the presence of a genetic modification or by the biosafety and biosecurity risks associated with that modification. We encourage NIH to adopt a risk-based approach and consider exclusions for common, low-risk molecular biology tools, established research models, and commercially available reagents. This would better align

oversight with actual risk and help ensure limited IBC resources remain focused on activities presenting the greatest potential concern.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

142. George Mason University

I am responding: On behalf of an organization

Name: Ericka Pearce, IBC Contact and Biosafety Officer on behalf of the George Mason University IBC

Name of Organization: George Mason University

Type of Organization: Institutional Research Oversight Committees e.g. IRB

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/12/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Broad Reporting Triggers and Undefined Terms

The George Mason University IBC supports NIH's goal of improving transparency and consistency in incident reporting. However, several reporting triggers rely on broad, undefined terms such as "any incident," "any compliance violation at any biosafety level," "potential exposure," and "potential laboratory-acquired infection." Without clearer definitions or regulatory triggers, institutions may interpret these terms differently, resulting in inconsistent reporting practices.

Several reporting categories also appear to overlap. For example, "any incident" at higher containment levels may be broader than the examples that follow; minor spills may be excluded in one section but potentially captured elsewhere; and animal bites, scratches, or compliance violations may be reportable even when no biohazard exposure or meaningful biosafety risk exists. Terms such as "basic first aid" and "agent-specific treatment" are also undefined.

The draft further creates uncertainty regarding the relationship between occupational health responsibilities and Principal Investigator (PI) responsibilities. While PIs are responsible for communicating required occupational health and exposure-response procedures, the policy does not clearly identify when an Occupational Health Surveillance Program is required, who determines that need, or who develops the procedures.

Operational Impact: Broad and overlapping reporting requirements may encourage reporting of low-risk events, near misses, and administrative issues, creating substantial burden for investigators, biosafety personnel, occupational health programs, IBCs, and recipients of these reports at the NIH Office of Science Policy (OSP). As one example, a laboratory injury at our institution that was currently non-reportable to NIH OSP required 6-8 hours of biosafety staff time, follow-up regarding corrective actions, as well as occupational healthcare practitioner and IBC review before closure. Expanding reporting to broadly defined "potential" events could significantly increase this workload without a corresponding biosafety or biosecurity benefit. Over-reporting may also reduce the effectiveness of reporting systems by making it more difficult to identify incidents that present significant biosafety or public health concerns.

Recommendation: NIH should provide clearer definitions, objective reporting thresholds, and better examples of reportable events. We encourage NIH to retain or incorporate more objective, risk-based terminology, such as "overt exposure," clarify occupational health responsibilities and triggers, and focus mandatory reporting on incidents that present meaningful biosafety, biosecurity, or public health concerns. This would promote more consistent implementation while ensuring limited oversight resources remain focused on the highest risk events.

143. Vicente Zuno Fernández

I am responding: On behalf of myself

Name: Vicente Zuno Fernández

Name of Organization: Houston Methodist Research Institute

Type of Organization: Non-Profit Research Organization

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/12/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): HMRI is a multidisciplinary biomedical research institution emphasizing the translation of laboratory discoveries into clinical applications.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The expanded scope of the policy is generally appropriate and reflects the need for comprehensive, risk-based biosafety oversight. However, clearer definitions and boundaries are necessary to ensure consistent implementation without imposing unnecessary administrative burdens on low-risk research. In particular, the definition of genetic modification should distinguish permanent genetic alterations from transient nucleic acid expression, such as mRNA-based applications. Replacing the detailed NIH Guidelines with a substantially abbreviated policy, without retaining established exemptions, examples, and interpretative guidance, create uncertainty regarding which activities require oversight and at what level. NIH should clearly distinguish exempt activities, delegated reviews, and full IBC reviews, while establishing consistent, risk-based criteria that prevent oversight gaps without unnecessarily expanding regulatory requirements.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered, risk-based oversight framework is appropriate, provided that responsibilities between federal agencies and local institutions are clearly defined. Local IBCs and BSOs should retain authority to assess and manage routine research activities based on institution-specific risks, while federal oversight should focus on higher-risk research, significant incidents, and activities requiring specialized review. The policy should establish clear criteria for escalating oversight, preserve institutional flexibility, and avoid duplicative administrative requirements. Additionally, federal expectations should be proportional to the actual biological risks involved rather than imposing uniform requirements across all research activities.

3. Continued utility of Risk Groups: Risk Groups (RGs) remain valuable as a baseline for biological risk assessment and should be retained within the proposed policy. However, RG classifications alone are insufficient to determine appropriate containment, particularly when organisms undergo genetic modifications that may alter pathogenicity, transmissibility, host range, or other biological characteristics. Biosafety Levels (BSLs), as described in the BMBL, provide a more comprehensive, activity-based framework that considers agent characteristics, experimental procedures, exposure potential, and available safeguards. NIH should preserve the distinction between RG classifications and

BSL containment requirements while emphasizing comprehensive, risk-based assessments conducted at the institutional level. This approach would provide flexibility without compromising biosafety or introducing unnecessary regulatory complexity.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary compliance by providing accessible guidance, standardized risk assessment tools, training resources, and model institutional policies. Voluntary adoption should remain flexible and risk-based, particularly for smaller institutions with limited biosafety resources. Clear distinctions between mandatory requirements and recommended practices would promote broader participation without creating unnecessary administrative or financial burdens.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed templates may improve consistency and transparency but should remain flexible and proportional to risk. Incident reporting should clearly distinguish events requiring immediate notification from those appropriate for routine institutional documentation. Reporting requirements should avoid duplicating information already captured through institutional incident management systems. Similarly, IBC meeting minutes should document substantive discussions and decisions without imposing excessive administrative burdens. Public disclosure requirements should adequately protect confidential research information, personnel privacy, and institutional security.

6. Other feedback relevant to this resource: NIH should provide comprehensive implementation guidance, including standardized risk assessment tools, clearer definitions, practical examples, and decision-making frameworks for determining oversight requirements. Additional guidance is particularly needed regarding BSO qualifications and responsibilities, IBC review thresholds, incident reporting criteria, and the distinction between mandatory requirements and recommended practices. Retaining relevant examples and interpretations from the existing NIH Guidelines would promote consistency and reduce uncertainty. NIH should also provide adequate transition periods, training resources, and technical assistance to support implementation without imposing unnecessary administrative burdens.

Uploaded File: Comments-for-Submission-Draft-NIH-Biosafety-Policy-10.7.2026.pdf

Description: Vicente Zuno - Comments for Submission - Draft NIH Biosafety Policy

October 7, 2026

Dear NIH OSP,

I appreciate the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. I submit these comments in my individual capacity as a biosafety professional with experience supporting IBC oversight, conducting biological risk assessments, investigating laboratory incidents, inspecting containment laboratories, and advising investigators.

I support NIH's effort to modernize biosafety oversight, expand the framework beyond recombinant and synthetic nucleic acid research, and establish a more risk-based system. However, several areas would benefit from clarification or additional guidance:

1. Qualifications and Competency Requirements for Biological Safety Officers

I strongly recommend that NIH establish minimum competency expectations for Biological Safety Officers (BSOs).

The draft assigns BSOs significant technical responsibilities, including inspection of containment facilities and equipment, assessment of compliance, investigation of incidents, identification of violations, and technical advice to investigators and the IBC. These functions require specialized knowledge and professional judgment, yet the draft specifies no minimum education, training, experience, or competency requirements.

NIH should establish a competency-based framework addressing areas such as biological risk assessment, containment, laboratory practices, incident investigation, applicable standards, and IBC oversight. Institutions could retain flexibility in demonstrating competency through education, experience, training, professional credentials, or a combination thereof.

2. Assignment of BSO Responsibilities to an "Other Official"

I am particularly concerned by the provision stating that, if an institution does not designate a BSO, another official must assume the BSO's responsibilities.

These responsibilities remain technical regardless of the title of the individual performing them. Incident investigation, containment assessment, laboratory inspection, and technical recommendations to an IBC require appropriate expertise.

NIH should remove this provision or clarify that any individual performing BSO functions must meet equivalent competency expectations. Otherwise, the Policy risks creating significant variability in the qualifications of those responsible for institutional biosafety oversight.

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

3. Circumstances Requiring Appointment of a BSO

NIH should reconsider limiting mandatory BSO appointment primarily to institutions conducting BSL-3/BSL-4 research or research involving GDMOs.

The proposed Policy expands biosafety oversight to wild-type biological agents, toxins, primary cells, and other biohazards. An institution could maintain a substantial BSL-2 program involving human pathogens while having significant responsibilities under the Policy without being required to designate a BSO.

NIH should either broaden the circumstances requiring a qualified BSO or provide criteria based on the size, complexity, and risk profile of an institution's research program.

4. Qualifications and Procedures for Delegated IBC Review

I support delegated review for appropriate lower-risk research, but additional guidance is needed regarding who may perform these reviews and under what conditions.

NIH should clarify whether delegated reviewers must be voting IBC members, whether a BSO may independently conduct delegated review, minimum reviewer competency, conflict-of-interest requirements, documentation expectations, and circumstances requiring elevation to full committee review.

A model delegated-review procedure would improve consistency among institutions while preserving institutional discretion to apply more restrictive review standards.

5. Activities Outside the Policy and Removal of Existing Exemptions

The draft identifies certain activities as outside the Policy but does not provide an exemption structure comparable to the current NIH Guidelines.

Clear boundaries are essential to prevent unnecessary administrative burden and inconsistent interpretation. NIH should develop a decision framework distinguishing:

- Activities outside the Policy;
- Activities not requiring IBC review;
- Activities eligible for delegated review;
- Activities requiring full IBC review; and
- Activities requiring both NIH and IBC review.

Representative examples of commonly conducted biomedical research would be particularly useful.

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

6. Incident-Reporting Thresholds and Public Posting

Additional guidance is needed to distinguish incidents requiring NIH reporting from those that may be managed institutionally.

Terms such as “minor spill,” “low-risk agent,” “breach of containment,” and “significant risk to human health” may be interpreted differently among institutions. NIH should provide a decision tree and representative examples identifying events requiring immediate NIH reporting, routine reporting, internal review only, or no formal reporting.

NIH should also establish clear standards for redacting publicly posted incident reports to protect personal and medical information, confidential research information, security-sensitive facility information, and ongoing investigations.

7. Relationship Between Risk Groups and Biosafety Levels

I encourage NIH to retain Risk Groups as one component of biological risk assessment while providing clearer guidance regarding their appropriate use.

Risk Group and Biosafety Level are not interchangeable. Risk Group describes characteristics of a biological agent, whereas containment level should result from a protocol-specific risk assessment considering the agent, procedures, concentration, volume, exposure routes, aerosol generation, animal models, genetic modifications, and other experimental factors.

Because confusion between RG classification and BSL assignment remains common, the new Policy provides an opportunity to clearly distinguish these concepts and reinforce protocol-specific risk assessment.

8. Implementation Guidance and Transition Period

The proposed Policy represents a substantial change in institutional biosafety oversight. Institutions may need to revise committee jurisdiction, procedures, electronic systems, delegated-review processes, incident-reporting procedures, institutional websites, training, and existing research registrations.

NIH should make implementation resources available well before the effective date. Particularly useful resources would include:

- A model Institutional Biosafety Assurance;
- A model IBC charter;
- A biosafety registration template;
- A delegated-review procedure;

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

- Scope and review-category decision trees;
- Incident-reporting guidance;
- BSO competency guidance;
- IBC and reviewer training materials;
- Public disclosure and redaction guidance; and
- Transition guidance for existing research.

These resources would be especially valuable to smaller institutions without dedicated biosafety or regulatory personnel.

9. Definition of Genetic Modification

I recommend that NIH revise or clarify the proposed definition of "genetic modification."

The draft includes introduction of nucleic acid molecules that "can be transcribed or translated." Transcription or translation alone, however, does not necessarily result in a stable or heritable genetic alteration.

For example, transient introduction of mRNA can result in translation of an encoded protein without altering the cellular genome. Likewise, non-integrating nucleic acid constructs may produce transient expression without creating a stable genetic modification.

NIH should clarify whether transient nucleic acid expression is intentionally being classified as "genetic modification." If such research is intended to remain within the Policy, terminology should distinguish transient nucleic acid expression from stable genomic modification. If not, the definition should be revised accordingly.

Clear terminology is essential because this definition directly affects whether research falls within the Policy and what oversight is required.

10. Clarity and Proportionality in Compliance and Enforcement

The proposed Policy includes potentially significant consequences for noncompliance, including additional terms and conditions, termination, and effects on future NIH funding decisions. Given the breadth of the Policy and its transition from detailed Guidelines to a more streamlined framework, NIH should clearly explain how compliance and enforcement determinations will be made.

NIH should clarify:

- How inadvertent or good-faith interpretive errors will be distinguished from serious, repeated, reckless, or intentional noncompliance;

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

- Whether institutions will ordinarily have an opportunity to implement corrective actions before severe enforcement measures;
- What factors will determine the severity of an enforcement response;
- How actual or potential biosafety risk will influence enforcement; and
- How NIH will address provisions reasonably subject to more than one interpretation.

A risk-based biosafety policy should be accompanied by a risk-based and proportionate compliance framework. Clear enforcement principles would encourage self-identification and correction of problems while reducing the risk of disproportionate consequences for ambiguous or low-risk compliance issues.

Conclusion

The proposed NIH Biosafety Policy is an important opportunity to modernize biological research oversight, but its success will depend on clear scientific terminology, qualified biosafety professionals, and sufficiently detailed implementation and enforcement guidance.

As NIH expands institutional responsibilities, it should establish appropriate competency expectations for BSOs and others performing BSO functions. Key definitions, including "genetic modification," should also be scientifically precise and avoid unintentionally capturing activities that do not constitute stable genetic alteration.

Finally, simplification of the current NIH Guidelines should not eliminate the examples and distinctions institutions need to understand their obligations. Where noncompliance may carry significant funding consequences, institutions should be able to determine prospectively what the Policy requires. A risk-based biosafety policy should therefore be supported by clear implementation guidance and a proportionate, risk-based compliance framework.

Thank you for considering these comments.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The level of detail requested per registration in the Draft Meeting Minutes Template is so onerous that it seems it would be easier to just attach copies of each entire registration. For instance, if no training concerns were discussed for a particular registration, why must every training for every listed personnel be included in the minutes? This, among other fields, will just become a copy-paste of 'Basic Biosafety, Bloodborne Pathogens, IBC Training...' etc. Likewise, shouldn't the Project Overview just be the Lay Summary? If a single registration utilizes 9 agents, are we expected to list every agent and describe each agent's characteristic, source, modification, experimental manipulation, etc.? Again, it would then just be easier to attach a PDF of the entire registration and write 'See attached' in the Template.

If required to use the provided Template, the minutes will be one long continuous table of information. Posting a PDF version of minutes to a public-facing website requires adherence to ADA requirements for the document. Making tables that cross multiple pages ADA compliant is a nightmare, adding significant administrative burden to the requirement of posting the minutes immediately after they are approved.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Having the incident reports be posted publicly is a deterrent for reporting; recommend instead that the institution be required to post aggregate annual reports that do not name individual investigators, with more strategic root cause analyses and mitigations. Also unclear how the institution is meant to do root cause analysis; for example, NASA defines "root cause analysis" for mishap investigations as organizational by definition. In other words, a "root cause" is always organizational. Done badly, this sort of analysis could always default to blaming upper management for being "negligent" or "underfunding" an area, or blaming the institution for "having a toxic culture". Therefore it seems more useful to have the institution do analyses across multiple incidents to come up with a strategic organizational response and set of remedies.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: There are major biosecurity implications with the details required in the incident reporting and meeting minutes templates. Requiring PI names along with their research and agents can make them an easy target for bad actors, specifically if working with biological select agents and toxins. Requiring any names on the minutes puts these individuals at risk for harassment and targeting, particularly government employees. Also, requiring the institution name, location, biosafety level, pathogen, and risk assessment provides bad actors with readily available information that could have dual use ramifications which flies in the face of biosecurity completely. At what cost are we willing to trade personnel and institution security to appease certain populations who do not understand the vulnerable position this presents for our institutions and our researchers? I cannot imagine anyone in the intelligence community, WMD coordinators, or security professionals are ok with this information being readily shared on a public facing website.

Name:

Name of Organization:

Type of Organization: Healthcare Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/13/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As written, "may be contaminated" could be interpreted to include virtually any primary human or animal cells (including any research involving NHP cells or tissues) for which the infectious-agent status of the source has not been comprehensively established.

NIH should define "adventitious agent," establish a risk-based threshold for determining when contamination is reasonably anticipated, and clarify whether donor screening, testing, source information, or other documentation can establish that primary cells do not fall within this category. The Policy should also clarify its application to commercially obtained cells, repository specimens, patient-derived cells, and primary animal cells and provide examples of included and excluded materials. A merely theoretical possibility of contamination should not independently trigger IBC oversight; the definition should be tied to a known or reasonably anticipated potential hazard to human health. Clear criteria are necessary to avoid additional administrative burden by unnecessarily expanding IBC oversight beyond research presenting a meaningful biosafety risk

The Policy does not provide sufficiently objective criteria for determining when a cell line qualifies as well-characterized, creating the potential for inconsistent interpretations among investigators, biosafety professionals, and IBCs. NIH should specify what level of information regarding identity, provenance, biological characteristics, and adventitious-agent testing is necessary; whether established commercially available or widely used cell lines may be presumed to satisfy the definition; and how primary, immortalized, genetically modified, and patient-derived cells should be treated. NIH should also provide examples of included and excluded cell lines. Because this determination may affect the scope and level of institutional oversight, a clear, risk-based definition is necessary to ensure consistent implementation and avoid additional administrative burden by unnecessary review of research that does not present a meaningful biosafety risk.

IBC review is appropriate for the review of research involving prions or biospecimens identified to be from a person or animal known to have a prion-based disease. However, the term self-aggregating is not

sufficiently defined to permit institutions or investigators to determine consistently if every protein that happens to aggregate or contributes to an aggregation-associated human disease, such as ALS, is also covered.

Protein aggregation alone does not necessarily establish a meaningful biosafety hazard. NIH should clarify whether "other self-aggregating proteins" is intended to encompass proteins with prion-like, seeding, propagation, transmissibility, pathogenic, or other specified hazard characteristics rather than any protein capable of aggregation. The definition should identify objective criteria and provide examples of both covered and excluded materials.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: It is recommended that NIH maintain the previously established categories of exempt research. NIH describes the purpose of the modernization as expanding oversight to biohazards while "removing red tape for low-risk research" and specifically asks commenters whether the proposed tiered oversight is appropriately calibrated to risk and administrative burden.

Exempt from IBC oversight is not synonymous with exempt from safe laboratory practice. Rather, it represents a determination that the incremental safety benefit of mandatory IBC oversight does not justify the administrative burden for a defined class of low-risk research. Currently exempt research was previously determined by NIH, following notice and opportunity for public comment, not to present a significant risk to health or the environment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It is recommended that NIH revise the approach to public posting of incidents so that detailed incident reports are submitted to NIH but are not routinely required to be posted publicly in their entirety. Alternatively, NIH could provide a template for public posting of standardized, de-identified high level summary information of incidents that might include root-cause categories and corrective actions. NIH could separately require disclosure of additional information when a particular incident presents a compelling public health or safety interest.

This approach balances transparency objectives with the equally important need to preserve a just, non-punitive reporting culture in which researchers and staff are encouraged to report incidents, near misses, and potential safety concerns promptly and completely. It also provides protections for researchers that are increasingly threatened or harassed due to the tools or subject matter of their research. Importantly, NIH would receive the information necessary to evaluate significant incidents, institutional responses, and compliance. The distinction would therefore be between information necessary for regulatory oversight and information necessary for public transparency, rather than assuming that the same level of detail is needed for both purposes.

6. Other feedback relevant to this resource: A six-month implementation period is insufficient given the breadth, complexity and institutional impact. Revising electronic systems to accommodate the new regulations is a significant challenge that will likely prevent many institutions' ability to meet this timeline. Additionally, updating policies and procedures and ensuring that researchers have the training

they need to understand the new requirements, including newly covered areas of research, will require additional time. The time required to identify newly covered research is one reason why it is critical for entities to be held to realistic and achievable implementation timelines.

NIH should provide a detailed description of the required elements of an institutional assurance and publish accompanying implementation guidance before policy adoption, including model assurance language, implementation templates, and sufficient lead time for institutions to develop. Administrative burden should be kept in mind in considering required elements.

The incorporation of delegated review has the potential to decrease regulatory burden and expedite review of low-risk research. However, the draft policy is unclear in what may qualify for delegated review.

- It appears that it is the intent that initial protocols only containing work identified as eligible for delegated review under Section IV-3. Clarified wording is recommended "for minor amendments to previously approved submissions or for initial research protocols"
- There are inconsistencies between the descriptions of research that require committee review (Section IV-2) and research that may be eligible for delegated review (Section IV-3). A potential clarification is to state that "Where research is described by both Section IV-2 and Section IV-3, research meeting all applicable criteria specified in Section IV-3 may undergo delegated review unless another characteristic of the research independently requires review under Section IV-1 or IV-2. A delegated reviewer may refer any submission to the full IBC when warranted based on the risk assessment."

Section IV-2 outlines the only clinical research provision and specifically identifies IBC review for biohazards that shed, replicate, integrate, require higher-risk manipulation, or involve RG2 or higher wild-type agents. There is no discussion of other genetically modified agents being used in clinical research, such as plasmids or RNA, and no discussion of exemptions. Given the federal administration's efforts to streamline and accelerate the development of innovative therapies through clinical trials, additional administrative burden should not be introduced by expanding IBC oversight in the clinical research arena.

The Policy should also exempt any covered clinical research studies from mandatory three-year de novo IBC review or permit an administrative continuation process confirming that no material changes affecting biosafety have occurred. Full IBC review should be required only for clinical research presenting local biosafety risk, where there may be questions regarding product handling and possible shedding. This approach would maintain appropriate biosafety oversight while reducing unnecessary regulatory burden

149. Amy Wilkerson

I am responding: On behalf of myself

Name: Amy Wilkerson

Name of Organization: The Rockefeller University

Type of Organization: Non-Profit Research Organization

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/13/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): broadly biomedical: Neuroscience, structural biology, immunology, virology, cancer biology, genetics, microbiology, mechanisms of human disease, organismal biology and evolution, computational biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Implementation period: The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research. Please allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.
Public disclosure and record retention: The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure. Please consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

150. Austin

I am responding: On behalf of myself

Name: Austin

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Role - Other: Research Compliance Officer

Date Submitted: 10/13/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: • The definition of "biohazard" will significantly affect program scope and administrative burden. NIH should provide additional examples and decision tools to promote consistent interpretation of covered biohazardous materials across institutions.
• How can institutions ensure consistent categorization of research activities when multiple biosafety risk factors exist? Many projects do not fit neatly into a single category. NIH should consider developing standardized case studies and decision-support tools to improve consistency in risk determinations across institutions.

Policy reference Section I
The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.
Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

Policy reference Section II
Coverage and decision rules
The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.
Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or

sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.
Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Assurance submission approval and renewal
A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.
Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.
Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.
Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Policy reference Section III B
Formal establishment and independent authority
The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.
Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language. The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.
As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions.

Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion

examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Committee procedures and conflicts of interest
The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.
Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

3. Continued utility of Risk Groups: Public disclosure and record retention
The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.
Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

Policy reference Section IV 1 with related petition provisions in Section III B
The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.
Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

Policy reference Sections V A through V E
The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.
Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): • What specific events require NIH notification? Institutions need greater certainty regarding reportable events and define or provide guidance on what is meant by "beyond first aid." NIH should provide clearer reporting thresholds and detailed examples of reportable and non-reportable biosafety incidents to improve consistency and reduce unnecessary reporting.

Policy reference Section III A
Accountability and minimum program support
The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.
Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.
Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.
Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Policy reference Section III C
The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.
Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.
Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data

and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident thresholds investigations and reporting
The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.
Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.
Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.
Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Policy reference Section III D
The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.
Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

6. Other feedback relevant to this resource: • How should IBCs coordinate with IACUCs when biosafety concerns arise during animal studies? NIH should provide guidance on effective coordination between IBC and IACUC oversight when animal activities involve covered biohazardous materials.
• Has NIH assessed the staffing and administrative burden associated with implementation? NIH should consider the resource implications for small and mid-sized research institutions and provide scalable implementation guidance and extended timelines. Implementation of expanded biosafety oversight responsibilities may require additional institutional resources, personnel expertise, training infrastructure, and administrative support.

• What level of review responsibility does NIH expect for subrecipients, collaborating institutions, and shared research facilities?
• Will NIH develop educational materials, case studies, and best-practice guidance that institutions can use to foster a culture of biosafety for research activities not formally subject to the policy?
• Can NIH provide voluntary training modules or awareness resources that institutions may offer to investigators whose research does not trigger regulatory review but involves biological materials or emerging technologies?
• Does NIH intend to provide scalable implementation models for institutions with varying levels of research activity, biosafety infrastructure, and staffing resources?
• Does NIH intend the Assurance to apply only to covered activities requiring biosafety oversight, or to all research involving biological materials conducted at the institution regardless of funding source or risk level?
• If an institution submits its Institutional Assurance in a timely manner but NIH review or approval extends beyond an implementation deadline, how will NIH assess institutional compliance during the interim period? Will institutions that have submitted an Assurance and implemented reasonable, good-faith oversight mechanisms be considered compliant pending NIH's final determination?
• When multiple institutions participate in a collaborative project, how should responsibility under the Assurance be allocated among participating institutions? Will NIH permit institutions to rely upon biosafety reviews performed by another assured institution, or is independent review expected at each collaborating organization?
• The draft policy references circumstances in which an Occupational Health and Safety Program may be required but does not clearly distinguish between mandatory requirements and recommended best practices. Can NIH provide specific criteria, examples, and minimum expectations to help institutions determine when an OHSP is required and what program elements must be implemented?

Implementation period
The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.
Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

Experienced program leadership and the Biological Safety Officer
The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.
Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.
Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office

director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B
Category boundaries and continuing review
Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.
Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.
Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Date Submitted: 10/13/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Gene Therapy Manufacturing

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Clarification on the impact of contracted manufacturing, supporting clinical and preclinical research, would be helpful. It's always been ambiguous if manufacturing of viral vectors, if not included directly in the grant, is obligated to be registered and follow NIH Guidelines. Funding is not provided directly by the NIH, and clear language around what is and is not included in the scope would assist with guidance and oversight for the growing biotech manufactuing industry.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): voluntary compliance should not include mandatory reporting / posting/ disclosure of IBC minutes in order to protect private IP also utilized by manufacturing organizations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

Description: NIH Biosafety Policy Comments

October 13, 2026

RE: Comments for the Draft NIH Biosafety Policy for Research Involving Biohazards (Request for Comment – NOT-OD-26-112, dated August 19, 2026)

To whom it may concern,

I am an associate professor that has been teaching and conducting research in infectious and vector borne diseases for the past 25+ years. The focus of my Ph. D. dissertation research was pathogenic bacteriology. During my career I have published multiple articles on vector-borne diseases and have presented my research and national and international meetings. I have also work closely with the regulatory and biosafety groups at my institution, so I have some experience with the current and past regulations. My comments regarding the Draft NIH Biosafety Policy for Research Involving Biohazards (the Policy) (NOT-OD-26-112, dated August 19, 2026) are below.

In general, I support the replacement of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines). However, I have concerns about the Policy, including the scope, definitions, and tiers of oversight, which are described further below.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.
    a. Increased Administrative Burden: The draft policy requires Risk Group assignments for non-recombinant agents, creating additional administrative workload for institutions.
    b. The proposed Policy uses words/terms but does not define them; some of these did not have definitions in the *NIH Guidelines*, and therefore this is a good opportunity to define these listed below:
        i. Organism
        ii. Transgenic
        iii. Adventitious agent
        iv. Virus as a “living organism”

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).

a. **General Definitions: *Toxin***
    i. The definition of toxin is poor. Clearly state that “living organism” does not include viruses.
    ii. Alternatively, adopt a clearer definition. For example, ISO35001 uses “substance, produced by plants, animals, protists, fungi, bacteria, or viruses, which in small or moderate amounts produces an adverse effect in humans, animals, or plants. This includes substances and materials, natural or as a result of biotechnology, that may contain toxins, any poisonous substance or any poisonous isomer, homologue, or derivative of such a substance.”
b. **Section IV-1 (Research that Requires NIH and IBC Approval Before Initiation): *Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL.***
    i. For researchers who identify new biological agents, there is no path to work with these agents. Once identified as an “emerging agent” with no risk group or biosafety level recommended in the BMBL, the research must be approved by NIH. However, without the ability to work on the agent, the researcher cannot generate the data required for NIH to conduct the risk assessment.
        1. **I recommend** that an initial characterization be allowed with the results to be shared with NIH to determine the appropriate Risk Group level.
    ii. Upon the Implementation Date of this Policy, what is the expectation for research with the many agents (especially bacteria and fungi) that are not listed in the BMBL, and are typically handled at BSL1 or BSL2?
        1. Are researchers expected to have obtained approved from the NIH by the Implementation Date? Does NIH OSP have the personnel to review and approve the requests that they will be inundated with?
c. **Section IV-2 (Research That Requires IBC Review and Approval Before Initiation): *Research involving RG3 or RG4 wild-type biological agents.***
    i. No comments on this section.
d. **Section IV-2: *Research with primary cells that may be contaminated by adventitious agents.***
    i. As noted above, the Policy does not define adventitious agents. Therefore, entities will be uncertain how to comply with this regulation.
    ii. If the intention of the Policy is to regulate primary cells that may be contaminated by bloodborne pathogens:
        1. **We recommend that:** This should not be regulated by this Policy as long as the entity is complying with OSHA Bloodborne Pathogens Standard or its equivalent.

2. **We recommend that:** If it must be regulated by this Policy, it should not fall under the category of requiring IBC approval and should at most be in Section IV-3, where delegated review is permitted.

iii. If the intention of the Policy is to regulate primary cells that may be contaminated by any unknown biohazard (including clinical or field samples):
   1. The recommendation is that the sample undergoes genetic testing and analysis initially or is characterized at high or maximum biocontainment.

e. **Section IV-2: *Research with wild type or genetically modified RG2 biological agents for which lower containment is requested, or research with wild type or genetically modified RG3 or RG4 biological agents that NIH has previously approved to be conducted at lower containment.***
   i. The Policy implies that there will be a workflow of (1) an entity submits an initial request for NIH to lower containment involving wild type or genetically modified RG3 or RG4 biological agents, (2) NIH will make a determination on whether that lower containment is appropriate, (3) NIH will be responsible for publishing approved determinations of appropriate lower containment for these agents, (4) subsequently, research involving these agents may be approved by the IBC alone (without NIH approval).
      1. This workflow should be expressly stated in the Policy to minimize confusion. This includes a clear statement that once NIH has made the determination and published it, other entities will not be required to obtain NIH approval.
      2. The method by which NIH will publish these determinations should be described, including the minimum time frame (e.g., determinations will be published within 3 months).
      3. The Policy should be clear on how much information will be released with these determinations (will it include information that will make sensitive information readily available to foreign adversaries?)

f. **Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): *Research conducted with transgenic organisms at BSL-1/ABSL-1.***
   i. The purchase and transfer of transgenic rodents requiring BL1 containment is exempt (Appendix C-VII). Further, the generation of BL1 transgenic rodents (Appendix C-VIII) is exempt in the NIH Guidelines. In 2011, NIH deemed that "… these breeding experiments do not pose an appreciable risk to human health or to the environment. In addition, while registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk." (January 19, 2011, Federal Register, January 19, 2011 (76 FR 3150)). As

documented in NIH guidance documents, the subsequent use of these BL1 transgenic rodents is also exempt (https://osp.od.nih.gov/wp-content/uploads/2022/11/Animal_Activities_Table.pdf). The same risk assessment should apply today, and the Policy should not require that work with transgenic rodents that can be housed at ABSL1 be approved by the IBC.

ii. As noted previously, there is no definition of *organism* in the Policy. Therefore, we recommend changing this to *animal* in this section.

iii. We understand that research with other transgenic animals has not had the time to demonstrate the same safety track record as transgenic rodents and therefore should continue to require IBC approval before that research is conducted.

iv. **We recommend that this be re-written** as: Research conducted with transgenic animals at BSL-1/ABSL-1, other than transgenic rodents.

g. **Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): *Research with genetically modified RG1 biological agents.***

i. Certain research (not requiring NIH-OSP approval and not involving DNA from RG3, RG4, or restricted organisms) with specific risk group 1 biological agents is exempt in the Guidelines (Appendices C-II, C-III, C-IV, and C-V), having been determined by the NIH Director to not present a significant risk to health or the environment. The Category here (research with genetically modified RG1 biological agents) is in contradiction to this determination and would require that work that was previously exempt now require IBC approval.

ii. **We recommend that this category be re-written as:** Research with RG1 biological agents is exempt as stated under the current policy.

h. **Several sections, including Section IV-2: *Research involving genetically modified cells, viruses, or organisms, other than plants (e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs)* and Section IV-3: *Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes***

i. An exemption for recombinant DNA molecules containing less than one-half of any eukaryotic viral genome that are propagated and maintained in tissue culture has existed at least since the Federal Register Notice in 1995 (Effective June 24, 1994, Published in Federal Register, July 5, 1994 (59 FR 34472)). The NIH Director has therefore determined that such experiments do not present a significant risk to health or the environment. While a single researcher registering for this work would not be a significant burden, the total number of registrations will constitute a significant collective administrative

burden on the IBC and researchers that is not commensurate with the very low biosafety risk.

ii. **We recommend that an exemption be added.**

i. **Section IV-3: *Research with biological toxin proteins not on the Select Agent list*.**
   i. The policy needs to be written clearly and concisely, which this category does not accomplish. As written, this would include food allergens, since they cause harm to humans, yet there is no indication that this is intended.
   ii. **We recommend that this be re-written as:** Research with biological toxin proteins with an LD_{50} in vertebrates of <100 micrograms per kilograms of body weight.
   iii. Additionally, a list of toxins currently classified under this category should be provided in the Policy.

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).
   a. Risk Group assignments have been removed from the NIH Guidelines and are not comprehensively provided in the BMBL. NIH should provide a definitive source or clear criteria for assigning Risk Groups to non-recombinant agents. Without standardized Risk Group classifications, institutions may reach different conclusions for the same agent, reducing consistency across the research community.
   b. Please provide the biosafety rationale and supporting evidence that prompted the inclusion of additional oversight requirements for research involving insect cell lines, non-human/NHP cell lines, and pathogens that are not capable of causing disease in humans, including immunocompromised individuals. Clarification of the specific risks, incident history, or emerging concerns that necessitate these requirements would help the research community understand the basis for the policy change and assess whether the proposed oversight is proportionate to the actual biosafety risk posed by these systems.
   c.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
   a. Additional clarification is especially in consideration of collaborations and/or contracts between non-NIH funded and funded institutions.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.
    a. The proposed definition of an incident appears overly inclusive and may capture events with minimal biosafety significance. A broad incident definition could result in unnecessary reporting requirements, diverting resources from investigating and addressing more consequential biosafety events.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.
    a. Refine the definition of a reportable incident and provide clearer thresholds for reporting to support a risk-based, consistent approach across institutions.

7. Other Comments
    a. The responsibilities of the institution (Section III-A) includes the following text (emphasis added) regarding records retention:
    The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states “the recipient and subrecipient must retain all Federal award records for **three years from the date of submission of their final financial report**.”
        i. The Policy is assuming that all IBC records are from projects that are NIH funded. The Policy has failed to consider projects that are not NIH funded and therefore will never submit a final financial report. As written, such IBC records may never be disposed of, which is either an oversight or egregious regulatory overreach. **This language needs to be changed.**
        ii. We recommend the following language:
    The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states “the recipient and subrecipient must retain all Federal award records for three years from the date of submission of their final financial report.” In the case of IBC records unrelated to Federal awards or where a final financial report is not submitted, it is unclear if documentation must be maintained for 1 year after IBC approval expires. This point need clarification.

8. Research with primary cells that may be contaminated by adventitious agents.

a. Provide a definition of adventitious agents.
b. Provide rationale on why primary cells require full IBC review, when wild-type (RG2/BSL2) agents can be reviewed through delegate review. The bulk of adventitious agents are categorized as risk group 2/BSL2 agents when isolated, cultured or purified, by definition this would imply that these agents can be reviewed and approved by delegate review.
c. For known clinical samples of higher risk group agents (Brucella, Herpes B, Mtb) the BMBL recommends BSL-2 practices, containment equipment, and facilities are recommended for routine handling of clinical specimens of human or animal origin. Why can't delegate review be assigned to these types of samples, with caveat that if samples are positively identified and research will continue, then full IBC review will be required?
d. Should this bullet be changed to highlight unscreened field or human samples from regions of endemic infections with RG3 and RG4 biological agents?

Reasons to remove from the scope of the Policy

- The work does not pose an appreciable risk to human health or to the environment.
- While registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk.
- Personnel who do not have access to biohazards, nor the ability to gain possession of biohazards, should not subject to the Policy. This is egregious regulatory overreach. As written, the individuals to whom this regulation will apply is broad and vague, which will lead to entities wasting time and effort to identify individuals, overtraining these individuals, and likely still being unable to fully comply with this poorly-written and obviously overreaching regulation. We strongly object to this requirement which will add significant burden to entity's without providing increased safety or security of biohazards.
    - What benefit is there in training an individual who performs administrative functions but does not have access to biohazards? How will training these individuals increase the safety or security of biohazards? This is a waste of resources with no clear benefit.
- Second, will entities be required to retroactively go back and add this information to their current inventory written records? How do the regulators expect this to be accomplished?
- This addition to the regulation will set entities up for failure, with no clear benefits to our biosafety programs.

- The Summary provided in the Policy does not provide an outlined justification for any of the following language changes to xxx. Thus, it is unclear why these changes are being proposed, how they will enhance the protection of human, animal, and plant health and safety, or how it will reduce the likelihood of the accidental or intentional release of a biohazard.

Issues to identify

- The definition is poorly written; regulatory language should be stated in clear, plain language. Such detailed examples should not be used in the regulatory language; if they are required, the original regulatory language is not sufficient and should be revised.
- Regulatory language should clearly and succinctly state a performance-based standard, which this definition fails to accomplish.
- Entities will be uncertain how to comply with this regulation, leading to chilling effects on the research community, additional administrative burden, and unintentional failures to comply.
- We recommend the following definition, based on xxx:
- The proposed definition removes the entity's ability to perform internal risk assessments to determine risk, thereby making all incidents involving biohazards reportable regardless of actual risk of escape and/or occupational exposure. The regulation must allow for the entity to perform risk assessments; it is important to recognize a risk assessment encompasses the whole picture of the event, not a single data point as these definitions imply. Risk assessments for events that may have resulted in an escape or potential occupational exposure are conducted within minutes to hours of potential exposure(s) and often incorporate a whole team of SMEs (biosafety, medical professionals, scientists, engineers) depending on the event to evaluate if the event resulted in escape of pathogen and/or if there was risk of occupational exposures.
- The additional reporting requirements will not enhance the protection of human, animal, or plant health and safety, reduce the likelihood of accidental or intentional release of a biohazard, or increase the probability that a release will be prevented from occurring.
- This change in definition will result in considerable administrative burden for entities with no real change in outcome or reduction in risk.
- Escape of a biohazard outside of primary containment should not require reporting unless a risk assessment has determined that the event resulted in a biohazard escaping beyond the defined biocontainment boundary (following the same definition in the FSAP HVAC policy statements) and/or causing an occupational exposure.

Good feedback

- This is a well written definition. Clear, concise, and with plain meaning. We support adding this definition to the regulations.

As stated previously, I support the replacement of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines) as many of my colleagues do. However, there are several areas of ambiguity in the proposed Policy that could lead to confusion and an unintended massive increase in the burden placed on IBC and researchers which will have the chilling effect of hindering research progress. I don't believe that is the goal of this new Policy.

Thank you for your consideration.

Description: Comments on the Draft Biosafety Policy from WCG Clinical, Inc.

October 13, 2026

NIH Office of Science Policy

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Response to NOT-OD-26-112 and 91 Fed. Reg. 176

We commend NIH for modernizing biosafety oversight and for its emphasis on transparency and risk-calibrated review. Our comments address the scope of the Policy (including its definitions) and the administrative burden of the IBC provisions, including the meeting minutes template.

Scope and Definitions:

i. The existing scope of NIH Guidelines extends to clinical trials conducted with gene transfer products developed with NIH funding. For example, when an academic medical center develops a product with NIH funding, a clinical trial of that product may be conducted at the originating institution and also at community clinics. Under current rules, such clinical trials require IBC oversight at all locations in the USA as long as research collaboration or contractual agreements apply. This means that staff, visitors, and the public near the community site where the product is being tested have equal and equitable protection of IBC oversight compared to staff and visitors at the academic medical center where the product was developed. This scope of applicability for clinical trials should be preserved for any new policy.

ii. The Draft Policy states, "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained."

This sentence could be construed to limit the scope of the Draft Policy to the point of irrelevancy. There are innumerable federal agencies, and any research in the US is also under the regulation or purview of multiple agencies, such as OSHA, EPA, CDC, and/or EEOC. The purview of the Equal Employment Opportunity Commission should not abrogate requirement for IBC review.

iii. The Draft Policy defines genetic modification as the "introduction of stable alterations into the genome by passaging, reassortment, chemical or radiological means." With regard to passaging, this would encompass almost all cell biology. Any passaged cell in cell culture will undergo some stable alteration, albeit non-deliberate and non-targeted. A more relevant definition could be "deliberate introduction of stable alterations". Inclusion of reassortment (especially with regard to influenza viruses) as form of genetic modification will be an improvement over current NIH Guidelines.

iv. The April 2024 revision to the NIH Guidelines (Section III-C-1) recognized that certain materials warrant oversight because they "[p]ossess biological properties that enable introduction of stable genetic modifications into the genome (e.g., cis elements involved in integration, gene editing)." The Draft Policy retains this concept in its definition of "genetic modification." However, Section II applies the definition only to "[c]ells, viruses, or organisms, other than plants, that have been genetically modified." It is therefore unclear whether the genome-modifying materials themselves are covered. These include gene-editing reagents delivered as nucleic acids, ribonucleoprotein complexes, or proteins, and non-viral and nanoparticle-based delivery systems. Such materials may never be a "genetically modified cell, virus, or organism" until after use, and some (e.g., Cas9 or base-editor protein) are not nucleic acids. The qualifier "known or potential risk to human health" adds further uncertainty. We recommend revising the scope of the Draft Policy to include "products or materials, regardless of composition or delivery method, that are intended to modify the genome of a cell, virus, or organism."

v. Extending the scope to include wild-type biological agents, as proposed, is a good idea.

Administrative Requirements and Meeting Minutes

We support NIH's transparency goals. We are concerned, however, about the cumulative administrative burden that would be placed on institutions, many of which are already struggling with research-related staffing and funding shortages.

i. The Draft Policy adds several recurring obligations to existing IBC work that would fall on IBC administrators and biosafety staff. Smaller institutions and those with a single part-time IBC coordinator will be affected most. The risk is that limited staff time will shift from substantive biosafety review to formatting, redaction, and web maintenance.

ii. The mandatory minutes template is too rigid and unnecessary. A single prescribed format cannot fit the range of institutions, committee structures, and protocol volumes that NIH funds. Institutions already keep minutes documenting quorum, conflicts of interest, deliberations, and determinations. Reformatting them adds work without improving biosafety. Instead, we suggest NIH allow institutions to keep their existing minutes formats, with NIH specifying only a minimum set of required elements.

iii. With regard to transparency, such a system means the public would have to search thousands of separate institutional websites to obtain information. Instead, we suggest NIH create a centralized online IBC meeting minutes database, where institutions would submit approved, appropriately redacted minutes through one portal, and NIH would make them available for public viewing. This would allow the public to search and compare IBC meeting minutes in a single repository, reduce institutional burden, and give NIH a single source for oversight and identification of biosafety-related trends.

Thank you for the opportunity to comment. We are happy to clarify any of our recommendations with NIH as needed.

On behalf of WCG Clinical, Inc.,

[redacted]

Christopher Doyle, PhD

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: NIH-Response.pdf

Recommendations to the National Institutes of Health Office of Science Policy

We support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the

documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a

convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.
2. Scope definitions and implementation

Policy reference Section II
Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered

research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.
Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Institutional accountability and Biosafety Assurances

Policy reference Section III A
Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs.

Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and

administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.
Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.
Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of

uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.
Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.
5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and

personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

3. Continued utility of Risk Groups: Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: IBC establishment functions and operations

Policy reference Section III B
Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Thank you for the opportunity to comment on the draft NIH Biosafety Policy. My laboratory studies the neuronal basis of neuropsychiatric disorders by studying how signaling between neurons is disrupted in zebrafish genetic models. In order to visualize parts of the nervous system in fish, we routinely make new transgenic lines by injecting plasmids grown in standard E Coli strains, and inject guide RNAs for CRISPR experiments, to introduce patient mutations. Over the course of a year, we create around 60 new plasmids (including intermediates) used to generate these transgenic fish, and test a similar number of guide RNAs, each of which we expect to induce novel genome mutations. Other labs in my field would use a roughly similar number of reagents. None of the work we do involves dual-use reagents or viruses. These experiments are extremely low-risk - in more than 20 years of research, I am unaware of public health hazards arising from this kind of research.

I respectfully ask NIH to consider the cumulative burden. Obtaining advance approval for each plasmid clone and guide RNA experiment is likely to take around 30 minutes of time, considering the need to assemble documentation, interact with the submission system and check for approval. Under the proposed changes, I anticipate spending around 60 hours per year on obtaining approval for my lab's genetic experiments. Few biomedical research labs have specialized administrative support that could help with this burden, which will therefore fall on lab heads and senior staff who have responsibility for laboratory administration. This will cut deeply into time that would be otherwise spent on conducting and analyzing experiments and mentoring junior staff.

For research that presents a biosecurity hazard, stringent oversight is essential. But for the well-established practices involved in ordinary plasmid cloning and zebrafish genetics, there is virtually no additional protection that will be gained from the new draft policy. I would be grateful if NIH would preserve an exemption for low-risk activities and make it clear that a review concluding that activities are

low-risk may cover a laboratory's entire research program. This would help protect to safety while making the best use of public resources by allowing scientists to focus their time where it can make the greatest difference.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed scope is too narrow. Section II defines research involving biohazards by reference to known or potential risk to human health, removing genetically modified plant research and agricultural and animal-restricted pathogens from Institutional Biosafety Committee (IBC) oversight. This weakens local protection of personnel, the community, and the environment, and is inconsistent with a One Health approach.

Other federal frameworks do not replace local review. The U.S. Department of Agriculture (USDA) Biotechnology Regulatory Services (BRS), USDA Animal and Plant Health Inspection Service (APHIS), and the Food and Drug Administration (FDA) regulate importation, interstate movement, environmental release, and product approval.

Work that could fall outside any local oversight includes:

• Genetically modified plants and plant-associated microbes in growth chambers and greenhouses, where containment prevents escape of transgenes, pollen, seed, or modified pests.
• Animal-restricted pathogens (e.g., porcine reproductive and respiratory syndrome virus, Marek's disease virus), where release could harm livestock, wildlife, and the agricultural economy without causing human disease.
• Genetically modified arthropods and aquatic species, including gene drive organisms, where the primary risk is ecological.
• Agents with uncharacterized zoonotic potential (e.g., novel animal coronaviruses or influenza viruses of animal origin), not known to cause human disease when the work begins.

We recommend that NIH define biohazards to include genetically modified organisms, biological agents, and toxins posing a known or potential risk to human, animal, or plant health or to the environment. Risk-based tiering of review, rather than excluding them from scope, would reduce the burden while preserving local oversight.

DEFINITIONS REQUIRING CLARIFICATION

The draft defines an “emerging agent or organism” as “[a]n agent or organism newly identified in nature.” That phrase carries the entire definition and is itself undefined. It is unclear whether it applies only to previously unknown agents or also to new strains, variants, and reassortants of known agents, and when an agent ceases to be newly identified. The distinction is consequential: under Section III-B, an IBC may not approve research with an emerging agent whose Risk Group classification or containment level is not available in Biosafety in Microbiological and Biomedical Laboratories (BMBL) until NIH authorizes it.

The 2009 H1N1 pandemic influenza virus illustrates the problem. The Centers for Disease Control and Prevention (CDC) initially recommended Biosafety Level 3 (BSL-3) containment because the emerging strain might cause more severe disease in specific populations than circulating strains; as risk assessment information accumulated, the recommendation moved to BSL-2 with enhancements, and then to BSL-2 once updated vaccines were available. Had such a strain required NIH authorization before work began, the research response would have been significantly delayed, slowing development of diagnostics, vaccines, and medical countermeasures when speed matters most. We recommend that NIH:

• Define the term “emerging agent or organism” precisely, including whether it covers new strains or variants of known agents and at what point the designation ends.
• In Sec. III-B, change "The IBC may not approve such research until authorized by NIH AND any other applicable Federal, State, or local entities" to "The IBC may not approve such research until authorized by NIH OR other cognizant Federal agency and any other applicable State or local entities."

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): We support the provision in Section IV-2 that deliberately transferring a clinical product into a participant under an FDA-regulated individual patient expanded access Investigational New Drug (IND) application or protocol, including for emergency use, is not research subject to this Policy and does not require IBC review. This avoids delays where a specific patient’s treatment is at stake.

We recommend extending a risk-based approach to clinical research under an IND more generally. FDA’s IND review addresses product quality and manufacturing, preclinical safety data, and participant protection; Institutional Review Board (IRB) review addresses human subject protections. A separate IBC review before initiation adds burden without corresponding safety benefit.

FEDERAL AUTHORIZATION FOR EMERGING, NOVEL, AND ZOONOTIC AGENTS

Section III-B requires institutions to petition NIH for the minimum biocontainment level for emerging, novel, or zoonotic agents whose Risk Group classification or containment level is not available in the BMBL, and provides that the IBC may not approve such research until NIH authorizes it; Section IV-1 places this research in the category requiring NIH approval. This could significantly delay public health preparedness and pandemic response.

SARS-CoV-2 illustrates the concern. CDC began issuing health advisories and guidance for clinicians and

clinical laboratories in January 2020; the NIH Office of Science Policy (OSP) did not issue guidance for handling and processing specimens until May 2020. During that interval, our infectious disease researchers began work immediately under our approved biosafety program, including expedited IBC review and review of safety testing of inactivated genomic material before transfer to our affiliated health system's clinical laboratories. That material validated an emergency-authorized test critical to the high level of local testing available early in the pandemic. Waiting for NIH authorization would have prevented this work.

The requirement also sits uneasily with NIH's expectations of the National and Regional Biocontainment Laboratories, which may be expected to realign their activities rapidly during a national emergency and to make their facilities, expertise, and resources available to support response efforts. They cannot do so if work with the emerging agent must await federal authorization. We recommend that NIH:

• Recognize other authoritative guidance. While NIH completes its approval process, allow work to begin on a provisional basis under biocontainment guidance for clinical and research laboratories from CDC, USDA APHIS, the World Health Organization, or comparable authorities, in addition to the BMBL.
• Create an institutional assurance pathway. Allow institutions to register a biosafety assurance permitting work with emerging and novel agents at the highest available biosafety level, with local IBC approval and simultaneous notification to NIH OSP, to support development of diagnostics and medical countermeasures.

DELEGATION OF REVIEWS

We support the provision in Section IV-3 allowing low-risk research to be reviewed through a delegated process. It will improve IBC efficiency and allow convened meetings to focus on higher-risk activities. We recommend two modifications:

• Wild-type Risk Group 1 agents. Delegated review should include wild-type Risk Group 1 agents capable of causing disease in animals, plants, and insects, reinforcing local IBC oversight of the institutional biosafety program as a whole.
• Cell lines. The provision for delegated review of "research with well-characterized cell lines" should read "well-established and well-characterized" cell lines. Misidentified cell lines and unrecognized contamination with adventitious agents are well documented, as noted in NOT-OD-17-068, Reminder: Authentication of Key Biological and/or Chemical Resources.

THREE-YEAR DE NOVO REVIEW

Section III-B provides that IBC approval should not exceed three years, after which a de novo registration submission and review is required. This adds significant burden for investigators and IBCs with little apparent benefit, since protocols must already be amended whenever agents or procedures change. The same assurance can be achieved through two mechanisms:

• Modifications. Require submission and review of a modification before any change in agents or procedures.

• Annual attestation. Require investigators to review each protocol annually, attest that it accurately describes their current work, and affirm that unanticipated results and incidents will be reported to the IBC immediately.

The requirement may also be counterproductive: investigators may respond by providing less detail in their protocols, reducing the quality of IBC risk assessments, and repeated review of unchanged protocols could reduce the attention IBCs give to new ones.

3. Continued utility of Risk Groups: Both designations should be retained, because they answer different questions. Risk Groups establish a baseline for evaluating agent-specific risk, tied to the parent organism — particularly valuable for genetically modified microorganisms — and account for risk both to the individual laboratory worker and to the community. Biosafety levels establish a baseline of risk-mitigation measures that allow work to proceed safely, including training, occupational health, facility design, engineering controls, and personal protective equipment. They are keyed to an agent's ability to cause disease in healthy adults, with enhancements for agents that can also cause disease in agricultural animals or plants. Both feed into the cycle of risk assessment, mitigation, and communication, and should be harmonized as much as possible.

HARMONIZATION AND THE PETITION PROCESS

It is unclear how NIH's biocontainment determinations under Section III-B will be distributed to other institutions, and whether they will be harmonized with the BMBL and other authoritative references in a timely way. Without a mechanism for publishing determinations, every institution must petition separately for the same agent, and institutions will reach different containment decisions for identical work.

Harmonization gaps already exist between the NIH Guidelines and the BMBL for arboviruses, where the American Committee on Arthropod-Borne Viruses Subcommittee on Arbovirus Laboratory Safety is the authoritative reference. We recommend that NIH publish all biocontainment determinations and reconcile Risk Group classifications with the BMBL and agent-specific authoritative references on a defined schedule.

CONTAINMENT REQUIREMENTS FOR HIGHLY PATHOGENIC AVIAN INFLUENZA LINEAGES

Section V-E requires BSL-3 enhanced containment and an occupational health plan for experiments with influenza viruses containing genes or segments from 1918–1919 H1N1, human H2N2 (1957–1968), and highly pathogenic avian influenza (HPAI) H5N1 strains within the Goose/Guangdong/96-like H5 lineage. Additional HPAI lineages have since emerged, including H7NX viruses and H5NX strains in sub-Saharan Africa, and work with viruses containing their genes or segments warrants the same containment. Under the Federal Select Agent Program, work with HPAI viruses is regulated as a biological select agent or toxin unless specifically exempted. To mitigate community, environmental, and economic risks, and to avoid requiring policy amendments each time a new lineage emerges, we recommend that NIH remove specific lineage designations and refer simply to highly pathogenic avian influenza viruses.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): As an NIH-funded institution, we have no comments on this section.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: MEETING MINUTES TEMPLATE

The level of detail required for meeting minutes creates a research security risk. Section III-B requires approved minutes to be posted on a public-facing institutional webpage, and Section III-A requires minutes and incident reports to remain posted for at least five years and be available on request. Minutes prepared to the template's standard would place in the public domain a consolidated record of which high-consequence agents an institution holds, which laboratories and buildings house them, the procedures used to manipulate them, and the containment and security measures in place. No single element may be sensitive alone; aggregated in a standardized, publicly posted document across every institution conducting this research, they constitute a significant conflict with the research security and Operations Security (OPSEC) objectives outlined in NIST IR 8484.

This runs counter to federal policy. Federal research security requirements, Dual Use Research of Concern and Pathogens with Enhanced Pandemic Potential (DURC/PEPP) oversight, and the Federal Select Agent Program (42 CFR Part 73, 7 CFR Part 331, and 9 CFR Part 121) all ask institutions to tighten control over exactly this information; select agent registration details, facility security plans, and inventory locations are protected from disclosure for well-established reasons. A template requiring public posting of agent identity, location, and methods would substantially undo that protection for work subject to IBC review, and would do so uniformly, giving a hostile actor a single reliable format to work from at every institution in the country.

The same requirement exposes unpublished federally funded research. Beyond trade secret and commercial information, detailed protocol descriptions would allow competing laboratories, domestic or foreign, to reconstruct unpublished work. Redaction cannot resolve this at reasonable cost: IBC staff are not positioned to judge which elements are proprietary or sensitive, so principal investigators must redact every protocol, adding to the burden the template already imposes. The detail requested is essentially equivalent to posting full protocols on an institutional website.

Detailed minutes also create personnel and facility security risks for research in sensitive areas, including animal models — particularly nonhuman primates — and human pathogen research. Groups that politicize this work circulate such material on social and conventional media. Redacting principal investigator names provides limited protection: the research described is usually sufficient to identify the laboratory, and facility directories then locate it. Our investigators and colleagues at peer institutions have experienced protests and threats of violence following similar disclosures.

The likely result is less information in protocols, not more: if investigators anticipate that agent, location, and procedural detail will be published, some will provide less of it, degrading the quality of IBC risk assessment and mitigation — the opposite of the policy's intent.

We recommend that NIH:

• Limit the content of posted minutes to the committee's determinations and the basis for them, without agent-specific, location-specific, or procedural detail.
• Provide fuller records to NIH and oversight bodies rather than to the public, preserving federal visibility without creating a public compilation of agents, locations, and methods.

INCIDENT REPORTING TEMPLATE

Requiring all incident reports to be posted, including Biosafety Level 1 and Animal Biosafety Level 1 (BSL-1/ABSL-1) incidents and bites or scratches from animals housed at ABSL-1, appears to advance transparency. In practice it duplicates the requirement that incident summaries appear in posted minutes and that complete reports and committee documentation be provided on request. It is unclear what additional benefit full posting provides.

The security concerns above apply with greater force here. An incident report identifies an agent, a location, and a specific failure of containment or practice at a specific facility. A public archive of such reports maps, for every institution, where the material is and where the weaknesses are.

Posting low-risk incidents also works against responsible risk communication. Consider an ABSL-1 transgenic rodent bite where the IBC determines the risk to the individual is low — limited to potential transfer of adventitious agents to the wound — and the risk to the community and environment is very low. Given how widely transgenic rodents are used, posting full reports for such events dilutes public attention to incidents that genuinely warrant it. That threshold also exceeds what other federal authorities require: under the Occupational Safety and Health Administration (OSHA) recordkeeping rule (29 CFR § 1904.7), an injury treated with first aid, such as flushing a wound and applying a bandage, is not recordable, and such treatment remains first aid even when administered by a licensed health care professional. We recommend that NIH:

• Allow posted minutes to serve as the record for BSL-1/ABSL-1 and BSL-2/ABSL-2 incidents and incidents involving transgenic animals housed at ABSL-1, reserving fuller reporting for incidents posing greater potential risk to personnel, the community, and the environment.
• Align the posting threshold with OSHA practice, so that incidents resolved with first aid, including first aid administered by a health care professional, are captured in committee minutes rather than as separately posted reports.
• Rely on the National Biosafety Data and Safety Analysis Center for trend analysis. We strongly support the Section III-C provision for voluntary, confidential, de-identified reporting of near-misses and secondary failures, and the assurance that NIH will not use voluntarily submitted data for enforcement or funding action. A de-identified national repository, modeled on the Department of Energy's OPEXShare and the NASA Aviation Safety Reporting System, will identify incident trends across institutions far more effectively than public posting of individual low-risk reports, and without the security consequences. NIH should expedite its implementation and treat it, rather than local public posting, as the mechanism for low-risk incident data.

6. Other feedback relevant to this resource: The definitions of "emerging agent or organism," "novel agent or organism," and "genetic modification" determine whether research requires federal or local review, and when that review must occur relative to the start of work. As drafted, they are not precise

enough to apply consistently, and ambiguity in any of them creates uncertainty about both the reviewing body and the permissible timeline.

Some cases are clear: mirror organisms and fully synthetic microorganisms plainly meet the definition of a novel agent, as organisms not existing in nature and deliberately designed. What remains unclear is whether a newly identified strain of a currently circulating, endemic agent is an emerging agent, since it has only recently been identified in nature. If it is, Section III-B appears to require NIH authorization before an IBC may approve the work whenever the strain's containment level is not available in the BMBL. Given how routinely new strains of endemic agents are identified, this determines whether a substantial volume of ordinary research is redirected to federal review. The definition of genetic modification raises a parallel question, since it extends to stable alterations introduced by passaging, reassortment, or chemical or radiological means — so a wide range of routine laboratory work could be treated as genetic modification.

Worked examples drawn from well-known case studies would be valuable to IBCs, particularly where they illustrate how to facilitate critical public health research safely and securely rather than only where to apply the most restrictive option. We recommend that NIH:

• Define each term explicitly, with particular attention to whether a newly identified strain of an endemic agent falls within emerging, and at what point an agent ceases to carry that designation.
• Publish worked scenarios mapping representative agents and modifications to the applicable review pathway and timing, including cases that resolve to local IBC review.

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

The proposed scope is too narrow. Section II defines research involving biohazards by reference to known or potential risk to human health, removing genetically modified plant research and agricultural and animal-restricted pathogens from Institutional Biosafety Committee (IBC) oversight. This weakens local protection of personnel, the community, and the environment, and is inconsistent with a One Health approach.

Other federal frameworks do not replace local review. The U.S. Department of Agriculture (USDA) Biotechnology Regulatory Services (BRS), USDA Animal and Plant Health Inspection Service (APHIS), and the Food and Drug Administration (FDA) regulate importation, interstate movement, environmental release, and product approval.

Work that could fall outside any local oversight includes:

- Genetically modified plants and plant-associated microbes in growth chambers and greenhouses, where containment prevents escape of transgenes, pollen, seed, or modified pests.
- Animal-restricted pathogens (e.g., porcine reproductive and respiratory syndrome virus, Marek's disease virus), where release could harm livestock, wildlife, and the agricultural economy without causing human disease.
- Genetically modified arthropods and aquatic species, including gene drive organisms, where the primary risk is ecological.
- Agents with uncharacterized zoonotic potential (e.g., novel animal coronaviruses or influenza viruses of animal origin), not known to cause human disease when the work begins.

We recommend that NIH define biohazards to include genetically modified organisms, biological agents, and toxins posing a known or potential risk to human, animal, or plant health or to the environment. Risk-based tiering of review, rather than exclusion from scope, would reduce burden while preserving local oversight.

Definitions requiring clarification

The draft defines an "emerging agent or organism" as "[a]n agent or organism newly identified in nature." That phrase carries the entire definition and is itself undefined. It is unclear whether it reaches only previously unknown agents or also new strains, variants, and reassortants of known agents, and when an agent ceases to be newly identified. The distinction is consequential: under Section III-B, an IBC may not approve research with an emerging agent whose Risk Group classification or containment level

is not available in Biosafety in Microbiological and Biomedical Laboratories (BMBL) until NIH authorizes it.

The 2009 H1N1 pandemic influenza virus illustrates the problem. The Centers for Disease Control and Prevention (CDC) initially recommended Biosafety Level 3 (BSL-3) containment because the emerging strain might cause more severe disease in specific populations than circulating strains; as risk assessment information accumulated, the recommendation moved to BSL-2 with enhancements, and then to BSL-2 once updated vaccines were available. Had such a strain required NIH authorization before work began, the research response would have been significantly delayed, slowing development of diagnostics, vaccines, and medical countermeasures when speed matters most. We recommend that NIH:

- Define the term “emerging agent or organism” precisely, including whether it covers new strains or variants of known agents and at what point the designation ends.
- In Sec. III-B, change "The IBC may not approve such research until authorized by NIH **AND** any other applicable Federal, State, or local entities" to "The IBC may not approve such research until authorized by NIH **OR** other cognizant Federal agency and any other applicable State or local entities."

2. Appropriateness of tiered oversight and calibration to risk (i.e., Federal versus local).

We support the provision in Section IV-2 that deliberately transferring a clinical product into a participant under an FDA-regulated individual patient expanded access Investigational New Drug (IND) application or protocol, including for emergency use, is not research subject to this Policy and does not require IBC review. This avoids delays where a specific patient’s treatment is at stake.

We recommend extending a risk-based approach to clinical research under an IND more generally. FDA’s IND review addresses product quality and manufacturing, preclinical safety data, and participant protection; Institutional Review Board (IRB) review addresses human subject protections. A separate IBC review before initiation adds burden without corresponding safety benefit.

Federal authorization for emerging, novel, and zoonotic agents

Section III-B requires institutions to petition NIH for the minimum biocontainment level for emerging, novel, or zoonotic agents whose Risk Group classification or containment level is not available in the BMBL, and provides that the IBC may not approve such research until NIH authorizes it; Section IV-1 places this research in the category requiring NIH approval. This could significantly delay public health preparedness and pandemic response.

SARS-CoV-2 illustrates the concern. CDC began issuing health advisories and guidance for clinicians and clinical laboratories in January 2020; the NIH Office of Science Policy (OSP) did not issue guidance for handling and processing specimens until May 2020. During that interval, our infectious disease researchers began work immediately under our approved biosafety program, including expedited IBC review and review of safety testing of inactivated genomic material before transfer to our affiliated health system’s clinical laboratories. That material validated an emergency-authorized test critical to the

high level of local testing available early in the pandemic. Waiting for NIH authorization would have prevented this work.

The requirement also sits uneasily with NIH's expectations of the National and Regional Biocontainment Laboratories, which may be expected to realign their activities rapidly during a national emergency and to make their facilities, expertise, and resources available to support response efforts. They cannot do so if work with the emerging agent must await federal authorization. We recommend that NIH:

- **Recognize other authoritative guidance.** While NIH completes its approval process, allow work to begin on a provisional basis under biocontainment guidance for clinical and research laboratories from CDC, USDA APHIS, the World Health Organization, or comparable authorities, in addition to the BMBL.
- **Create an institutional assurance pathway.** Allow institutions to register a biosafety assurance permitting work with emerging and novel agents at the highest available biosafety level, with local IBC approval and simultaneous notification to NIH OSP, to support development of diagnostics and medical countermeasures.

Delegation of reviews

We support the provision in Section IV-3 allowing low-risk research to be reviewed through a delegated process. It will improve IBC efficiency and allow convened meetings to focus on higher-risk activities. We recommend two modifications:

- **Wild-type Risk Group 1 agents.** Delegated review should include wild-type Risk Group 1 agents capable of causing disease in animals, plants, and insects, reinforcing local IBC oversight of the institutional biosafety program as a whole.
- **Cell lines.** The provision for delegated review of "research with well-characterized cell lines" should read "well-established and well-characterized" cell lines. Misidentified cell lines and unrecognized contamination with adventitious agents are well documented, as noted in NOT-OD-17-068, Reminder: Authentication of Key Biological and/or Chemical Resources.

Three-year de novo review

Section III-B provides that IBC approval should not exceed three years, after which a de novo registration submission and review is required. This adds significant burden for investigators and IBCs with little apparent benefit, since protocols must already be amended whenever agents or procedures change. The same assurance can be achieved through two mechanisms:

- **Modifications.** Require submission and review of a modification before any change in agents or procedures.
- **Annual attestation.** Require investigators to review each protocol annually, attest that it accurately describes their current work, and affirm that unanticipated results and incidents will be reported to the IBC immediately.

The requirement may also be counterproductive: investigators may respond by providing less detail in their protocols, reducing the quality of IBC risk assessments, and repeated review of unchanged protocols could reduce the attention IBCs give to new ones.

3. Continued utility of Risk Groups as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels outlined in the BMBL.

Both designations should be retained, because they answer different questions. Risk Groups establish a baseline for evaluating agent-specific risk, tied to the parent organism — particularly valuable for genetically modified microorganisms — and account for risk both to the individual laboratory worker and to the community. Biosafety levels establish a baseline of risk-mitigation measures that allow work to proceed safely, including training, occupational health, facility design, engineering controls, and personal protective equipment. They are keyed to an agent's ability to cause disease in healthy adults, with enhancements where an agent can also cause disease in agricultural animals or plants. Both are inputs to the cycle of risk assessment, mitigation, and communication, and should be harmonized to the extent possible.

Harmonization and the petition process

It is unclear how NIH's biocontainment determinations under Section III-B will be distributed to other institutions, and whether they will be harmonized with the BMBL and other authoritative references in a timely way. Without a mechanism for publishing determinations, every institution must petition separately for the same agent, and institutions will reach different containment decisions for identical work.

Harmonization gaps already exist between the NIH Guidelines and the BMBL for arboviruses, where the American Committee on Arthropod-Borne Viruses Subcommittee on Arbovirus Laboratory Safety is the authoritative reference. We recommend that NIH publish all biocontainment determinations and reconcile Risk Group classifications with the BMBL and agent-specific authoritative references on a defined schedule.

Containment requirements for highly pathogenic avian influenza lineages

Section V-E requires BSL-3 enhanced containment and an occupational health plan for experiments with influenza viruses containing genes or segments from 1918–1919 H1N1, human H2N2 (1957–1968), and highly pathogenic avian influenza (HPAI) H5N1 strains within the Goose/Guangdong/96-like H5 lineage. Additional HPAI lineages have since emerged, including H7NX viruses and H5NX strains in sub-Saharan Africa, and work with viruses containing their genes or segments warrants the same containment. Under the Federal Select Agent Program, work with HPAI viruses is regulated as a biological select agent or toxin unless specifically exempted. To mitigate community, environmental, and economic risks, and to avoid a policy requiring amendment each time a new lineage emerges, we recommend that NIH remove the specific lineage designations and refer simply to highly pathogenic avian influenza viruses.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).

As an NIH-funded institution, we have no comments on this section.

5. Comments on the draft incident reporting and meeting minutes templates.

Meeting minutes template

The level of detail required for meeting minutes creates a research security risk. Section III-B requires approved minutes to be posted on a public-facing institutional webpage, and Section III-A requires minutes and incident reports to remain posted for at least five years and be available on request. Minutes prepared to the template's standard would place in the public domain a consolidated record of which high-consequence agents an institution holds, which laboratories and buildings house them, the procedures used to manipulate them, and the containment and security measures in place. No single element may be sensitive alone; aggregated in a standardized, publicly posted document across every institution conducting this research, they constitute a significant conflict with the research security and Operations Security (OPSEC) objectives outlined in NIST IR 8484.

This runs counter to federal policy. Federal research security requirements, Dual Use Research of Concern and Pathogens with Enhanced Pandemic Potential (DURC/PEPP) oversight, and the Federal Select Agent Program (42 CFR Part 73, 7 CFR Part 331, and 9 CFR Part 121) all ask institutions to tighten control over exactly this information; select agent registration details, facility security plans, and inventory locations are protected from disclosure for well-established reasons. A template requiring public posting of agent identity, location, and methods would substantially undo that protection for work subject to IBC review, and would do so uniformly, giving a hostile actor a single reliable format to work from at every institution in the country.

The same requirement exposes unpublished federally funded research. Beyond trade secret and commercial information, detailed protocol descriptions would allow competing laboratories, domestic or foreign, to reconstruct unpublished work. Redaction cannot resolve this at reasonable cost: IBC staff are not positioned to judge which elements are proprietary or sensitive, so principal investigators must redact every protocol, adding to the burden the template already imposes. The detail requested is essentially equivalent to posting full protocols on an institutional website.

Detailed minutes also create personnel and facility security risks for research in sensitive areas, including animal models — particularly nonhuman primates — and human pathogen research. Groups that politicize this work circulate such material on social and conventional media. Redacting principal investigator names provides limited protection: the research described is usually sufficient to identify the laboratory, and facility directories then locate it. Our investigators and colleagues at peer institutions have experienced protests and threats of violence following similar disclosures.

The likely result is less information in protocols, not more: if investigators anticipate that agent, location, and procedural detail will be published, some will provide less of it, degrading the quality of IBC risk assessment and mitigation — the opposite of the policy's intent.

We recommend that NIH:

- Limit the content of posted minutes to the committee's determinations and the basis for them, without agent-specific, location-specific, or procedural detail.
- Provide fuller records to NIH and oversight bodies rather than to the public, preserving federal visibility without creating a public compilation of agents, locations, and methods.

Incident reporting template

Requiring all incident reports to be posted, including Biosafety Level 1 and Animal Biosafety Level 1 (BSL-1/ABSL-1) incidents and bites or scratches from animals housed at ABSL-1, appears to advance transparency. In practice it duplicates the requirement that incident summaries appear in posted minutes and that complete reports and committee documentation be provided on request. It is unclear what additional benefit full posting provides.

The security concerns above apply with greater force here. An incident report identifies an agent, a location, and a specific failure of containment or practice at a specific facility. A public archive of such reports maps, for every institution, where the material is and where the weaknesses are.

Posting low-risk incidents also works against responsible risk communication. Consider an ABSL-1 transgenic rodent bite where the IBC determines the risk to the individual is low — limited to potential transfer of adventitious agents to the wound — and the risk to the community and environment is very low. Given how widely transgenic rodents are used, posting full reports for such events dilutes public attention to incidents that genuinely warrant it. That threshold also exceeds what other federal authorities require: under the Occupational Safety and Health Administration (OSHA) recordkeeping rule (29 CFR § 1904.7), an injury treated with first aid, such as flushing a wound and applying a bandage, is not recordable, and such treatment remains first aid even when administered by a licensed health care professional. We recommend that NIH:

- Allow posted minutes to serve as the record for BSL-1/ABSL-1 and BSL-2/ABSL-2 incidents and incidents involving transgenic animals housed at ABSL-1, reserving fuller reporting for incidents posing greater potential risk to personnel, the community, and the environment.
- Align the posting threshold with OSHA practice, so that incidents resolved with first aid, including first aid administered by a health care professional, are captured in committee minutes rather than as separately posted reports.
- **Rely on the National Biosafety Data and Safety Analysis Center for trend analysis.** We strongly support the Section III-C provision for voluntary, confidential, de-identified reporting of near-misses and secondary failures, and the assurance that NIH will not use voluntarily submitted data for enforcement or funding action. A de-identified national repository, modeled on the Department of Energy's OPEXShare and the NASA Aviation Safety Reporting System, will identify incident trends across institutions far more effectively than public posting of individual low-risk reports, and without the security consequences. NIH should expedite its implementation and treat it, rather than local public posting, as the mechanism for low-risk incident data.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

The definitions of "emerging agent or organism," "novel agent or organism," and "genetic modification" determine whether research requires federal or local review, and when that review must occur relative to the start of work. As drafted, they are not precise enough to apply consistently, and ambiguity in any of them creates uncertainty about both the reviewing body and the permissible timeline.

Some cases are clear: mirror organisms and fully synthetic microorganisms plainly meet the definition of a novel agent, as organisms not existing in nature and deliberately designed. What remains unclear is whether a newly identified strain of a currently circulating, endemic agent is an emerging agent, since it has only recently been identified in nature. If it is, Section III-B appears to require NIH authorization

before an IBC may approve the work whenever the strain's containment level is not available in the BMBL. Given how routinely new strains of endemic agents are identified, this determines whether a substantial volume of ordinary research is redirected to federal review. The definition of genetic modification raises a parallel question, since it extends to stable alterations introduced by passaging, reassortment, or chemical or radiological means — so a wide range of routine laboratory work could be treated as genetic modification.

Worked examples drawn from well-known case studies would be valuable to IBCs, particularly where they illustrate how to facilitate critical public health research safely and securely rather than only where to apply the most restrictive option. We recommend that NIH:

- Define each term explicitly, with particular attention to whether a newly identified strain of an endemic agent falls within emerging, and at what point an agent ceases to carry that designation.
- Publish worked scenarios mapping representative agents and modifications to the applicable review pathway and timing, including cases that resolve to local IBC review.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: This is so vague and unclear. Needs more defined definitions and how it is more tiered to decreasing bureaucracy. How it is written creates more red tape that a researcher has to navigate even for low risk research

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The biosafety team needs more oversight and empowerment it is not clear in this draft

3. Continued utility of Risk Groups: Bmbl focuses on containment not risk groups. Make the bmbl more policy that recommendations and it would hold more power

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): There's nothing here that forces private companies to comply. In fact this drives more people to go private with less required oversight

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Absolutely should not be required. This is forcing a square peg into a round hole. Required elements are fine.

6. Other feedback relevant to this resource: Needs a lot of runway too implement and not just 6 months. Needs a lot of implementation guidance and webinars to inform scientists how this affects them. Just send more red tape with little eye to safety

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: the policy should not be changed. It is not appropriate. It is far too restrictive, puts too much strain on research and will impede research. It also may punish investigators for simply seeking to do fundamental biological research to understand the world around us.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): not appropriate. Too much federal involvement and too restrictive

3. Continued utility of Risk Groups: defining biohazards beyond what is already included is excessive.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): publicly outing scientists by posting mistakes will discourage discovery and detract from human health.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

161. European Research Infrastructure on Highly Pathogenic Agents (ERINHA AISBL)

I am responding: On behalf of an organization

Name: Jonathan Ewbank

Name of Organization: European Research Infrastructure on Highly Pathogenic Agents (ERINHA AISBL)

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/14/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Pandemic preparedness

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The text reads, "For the purpose of the scope of this Policy, research involving biohazards is defined as research involving known or potential risk to human health and any of the following:
1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above".
There is therefore currently no definition of "biohazard". This should be rectified. A proposition is given below.

The inclusion of "Cells or organisms, other than plants, containing" "other self-aggregating proteins" (i.e. 3) is inappropriately broad and requires explicit qualification.

Managing the risks from biohazards (i.e. biorisk management) requires the overlapping elements of good biosafety and laboratory biosecurity practice (see for example, Figure 1.1 in Laboratory biosecurity guidance. Geneva: World Health Organization; 2024, a reference document reviewed before publication both by the American Biological Safety Association (ABSA) International and the US government). These include in the areas of Risk assessment, Programme management, Inventory control, Access restriction, Accountability and compliance, Reporting and response, Training and drills, Transfer and transport, Decontamination and, waste management. Section I starts, "As the world's largest public funder of biomedical research, NIH is committed to ensuring that gold-standard science is conducted under gold-standard biosafety conditions", and ends, "to help ensure the safe, responsible, and secure conduct of such research". Thus, although there is thus an implicit recognition of the complementary importance of biosecurity, it is explicitly excluded from the policy. Indeed, the word "biosecurity" only occurs once, in Section III-B, to qualify the perimeter of IRB competences. This is more than a semantic issue. We recommend that the important and inseparable role of biosecurity in the oversight of research with biohazards be reflected in a revised policy.

The inadvertent release of different classes of engineered plants has the potential to cause harm to humans (e.g. plants producing heterologous allergens), other animals (e.g. plants producing heterologous toxins), plants (e.g. invasive plants with increased fitness) and the environment. The omission of plants from the Scope does not align with normal precautionary principles. Similarly, the qualification, “other than plants” in Section IV-2 does not appear to be warranted.

The definition, “Biological agent: Bacteria, viruses, fungi or parasites that cause human disease” is more constrained than definitions that are widely used. We recommend, “A microorganism, virus, biological toxin, particle, or otherwise infectious material, either naturally occurring or genetically modified, which may have the potential to cause infection, allergy, toxicity, or otherwise create a hazard to humans, nonhuman animals, or plants”. And generally, the use of the definitions provided in WHO publications, written with US government support, is recommended as this policy will have a global reach. The 2022 Global guidance framework for the responsible use of the life sciences; Mitigating biorisks and governing dual-use research” would be an appropriate source. This could also help clarify some of the current confusion regarding terms such as biohazard. [“A hazard does not become a “risk” until the likelihood and consequences of that hazard causing harm are taken into account”].

The definition of “Genetic modification” (The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:) includes, “The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means”. This is incoherent because it is trying to fit under one umbrella two distinct categories of genome modification. This could be resolved thus:
Genetic modification:
· The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
– Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
– Have the potential for one or more cycles of replication in a cell; or
– Can be transcribed or translated.
· The production of cells, organisms, or viruses with stable alterations of their genomes by passaging, reassortment, chemical or radiological means.

The qualification, “deliberately designed”, is an unwarranted restriction of the scope of “Novel agent or organism”.
The qualification, “without deliberately introduced genetic modifications” is unnecessary for the definition of “Wild type”.
“A confirmed or potential laboratory-acquired infection (LAI)” should be replaced by “laboratory-associated infection” as this also covers secondary and tertiary infections.

Taking these elements into consideration, we propose the following:
“For the purpose of the scope of this Policy, a biohazard is defined as being any of the following:
1. Wild-type pathogens;
2. Cells, viruses, or organisms, that have been genetically modified;

3. Prions, or other self-aggregating proteins associated with transmissible disease; or
4. Toxins.
Cells or organisms that are themselves not biohazards, but that harbor any one of the 4 classes of biohazard listed above are also considered to fall under the scope of this Policy".

There is an apparent gap regarding information security. For example, there is a proposed requirement for an IRB to post "all incident reports on a public-facing webpage on the website of the institution, using the required incident reporting template". While transparency is a laudable goal, certain information may be in itself a biosecurity risk and provisions need to be made to deal with such contingencies.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: The "IBC Functions" under Section III-B. Responsibilities of the Institutional Biosafety Committee (IBC), include, "Petitioning NIH for determination of the minimum biocontainment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available in the BMBL. The IBC may not approve such research until authorized by NIH and any other applicable Federal, State, or local entities". Unless the policy is intended to be used to prohibit any and all experimentation with particular future emerging or zoonotic biological agents, it would be expedient to include a provision that under exceptional circumstances, during a public health emergency, for example, allows provisional IBC approval without prior NIH authorization, if, and only if, the research is to be carried out under BSL4 conditions. This carve-out would not be appropriate for novel biological agents. Similar considerations apply to Section IV-1. Research That Requires NIH and IBC Approval Before Initiation.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: While the duties of the Biological Safety Officer (BSO) [more commonly termed simply "biosafety officer"] are given, it would be appropriate to provide guidance regarding their required competencies and experience. This applies equally to the official that "the institution must assign" "to take on these responsibilities" in the absence of a BSO.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public reporting they way it is written to be done in the proposed policy crushes the culture of trust between the researchers and the Health & Safety Office of the institution. Such reporting will result in lower overall reporting of incidents to safety professionals and less outreach asking for support when things do go wrong. Safety professionals work very hard to build up these relationships with researchers at their institutions and to create that needed trust and source of support. Requiring institutions to report out all exposures with biological material and include names and details will break that trust. This is also most likely a major HIPAA violation by sharing protected information or information about an incident where others could easily search institutional website to identify they names of students, staff, and post-docs that were involved in the that incident.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Under organisms, are all strains of transgenic mice included? Will the NIH provide instructions on how to evaluate these strains, as the genetic material introduced to these mice are usually not hazardous or present a risk? Most transgenic mouse strains do not cause human or animal disease and there is no risk to using these animals, besides the inherent risk of the animal itself. There is no need to perform a risk assessment on these animals as far at the transgenes are concerned. Under Appendix C-VII of the NIH Guidelines, the purchase or transfer of transgenic rodents that may be housed under BL1 containment are activities that are exempt from the NIH Guidelines. What elements would need to be registered and reviewed if such animals now need to be registered? Please note that this would also be an insane burden on biosafety programs, as there are often 50+ strains of varying transgenic mice used in a single IACUC protocol. Spending time to evaluate all of these strains would bring no risk benefit to the researcher or the institution and take valuable time away from other tasks.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Major Comments
Positive Aspects of the Draft Policy
The draft advances several important modernization goals by:
• Expanding oversight beyond recombinant and synthetic nucleic acid methodologies;
• Bringing wild-type biological agents into the oversight framework;
• Recognizing emerging technologies and novel biological risks;
• Attempting to establish more structured incident-reporting categories and timelines;
• Increasing transparency; and
• Acknowledging the need for implementation resources.
Need for Greater Interagency Harmonization
The draft frequently references other federal agencies but does not establish mechanisms for resolving overlapping jurisdictional questions or conflicting regulatory interpretations. This is particularly concerning given the continued ambiguity surrounding:
• Plant pathogens;
• Animal pathogens;
• USDA-regulated activities;
• FDA-regulated clinical activities;
• Select Agent programs; and
• Environmental release activities.
Without stronger coordination mechanisms, institutions may continue to face fragmented and inconsistent oversight requirements.
The modernization initiative appropriately seeks to broaden oversight beyond traditional recombinant DNA frameworks. However, several definitions and concepts appear to differ from terminology already used by NIH, USDA, CDC, EPA, and other federal agencies.
Examples include terminology related to:
• Novel organisms;

• Genetically engineered organisms;
• Animal pathogens;
• Plant pathogens;
• Environmental release; and
• Containment classifications.

Differences in terminology create opportunities for inconsistent interpretation and may increase regulatory burden for institutions conducting research subject to multiple federal oversight frameworks. NIH should work with partner agencies to harmonize terminology wherever possible and publish joint guidance when differences cannot be avoided. A formal interagency biosafety coordination mechanism would further improve consistency and reduce regulatory confusion.

The Policy Does Not Address Continuity of Large-Scale Biosafety Requirements

Replacing the current NIH Guidelines also raises a significant continuity question for large-scale biosafety. Appendix K currently provides nationally recognized physical-containment and operational practices for large-scale work involving viable organisms containing recombinant or synthetic nucleic acid molecules, and BMBL Appendix M expressly refers to Appendix K as a source of practices applicable to large-scale work involving both genetically modified and non-genetically modified biological materials. The proposed Policy does not state whether Appendix K will remain effective, be incorporated into binding implementation materials, be superseded by BMBL Appendix M, or be replaced by another maintained standard.

This omission could leave institutions, production facilities, and the professionals who evaluate large-scale systems without a clear federal baseline for matters such as closed systems, transfer operations, aerosol generation, inactivation, waste handling, utilities, and process-specific engineering controls. It is also notable that the draft no longer identifies large-scale work as an independent trigger for mandatory appointment of a BSO.

NIH should identify the future status of Appendix K, the applicability of large-scale containment provisions to recombinant, genetically modified, and non-recombinant biological materials, the respective status of mandatory and advisory provisions, the qualifications and institutional expertise expected for large-scale work, and the federal entity responsible for maintaining and updating this guidance.

Other-agency oversight language could be read as either substitution or duplication

The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. It does not say whether NIH-policy oversight is displaced, deemed satisfied, or remains concurrent.

This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. NIH should adopt a function-specific reliance framework rather than treating another federal program as either wholly substitutive or wholly duplicative. A federal permit, inspection, registration, accreditation, or approval may already establish particular facts concerning facilities, containment features, training, personnel qualifications, permitted activities, or required controls without resolving the entire research-specific biosafety assessment. Institutions should be permitted to incorporate and rely upon those findings for the questions they actually address while retaining IBC responsibility for experimental features or local conditions not resolved through the other process.

NIH should publish an issue-specific crosswalk identifying potentially overlapping federal programs, the functions that may be satisfied through reliance, the documentation needed to establish reliance, the

limits of that reliance, and the responsibilities that remain with the institution or IBC. This would reduce duplicative review without incorrectly treating distinct federal programs as interchangeable.

The Exclusion of Genetically Modified Plants Creates a Significant Regulatory Gap

The draft repeatedly recognizes environmental risk, unintended release, ecological impacts, environmental containment, population-level consequences, and the potential for broader environmental effects arising from biotechnology research. At the same time, genetically modified plants are expressly excluded from the scope of the policy. This exclusion is difficult to reconcile with the policy's stated objectives and risk-assessment framework.

At a minimum, genetically modified plants may present plausible food or feed safety concerns, agricultural impacts, ecological consequences, environmental persistence, gene flow, or other environmental risks that warrant institutional review and risk assessment. The draft requires IBCs to evaluate environmental risks and, in some circumstances, maintain expertise in ecological and environmental risk assessment, yet expressly excludes a major category of research capable of creating agricultural, ecological, food or feed, and other environmental consequences.

More broadly, the plant exclusion illustrates a recurring challenge throughout the draft: the absence of a clearly coordinated federal oversight framework. Federal oversight of biotechnology products is distributed principally among USDA, FDA, and EPA under the Coordinated Framework for the Regulation of Biotechnology. However, product-focused regulatory authorities do not necessarily provide continuous institutional oversight of all contained research activities preceding product development, field testing, environmental release, or commercialization. The draft does not explain whether NIH considers those product-focused authorities sufficient to replace institutional biosafety oversight during the research phase, or how occupational, containment, biosecurity, and environmental risks falling outside a defined regulatory trigger should be addressed.

If NIH intends to exclude plant research because it believes other federal agencies provide sufficient oversight, the policy should explicitly state that rationale and clearly describe where responsibility transfers from institutional biosafety oversight to other regulatory programs. As written, the policy does neither. The result is uncertainty regarding whether plant-related research falls outside oversight entirely, is expected to be reviewed under another federal framework, or remains subject to institutional review through some mechanism not described in the policy.

NIH should either incorporate appropriate oversight of genetically modified plants within the policy's scope or clearly articulate the interaction between NIH requirements and USDA, FDA, and EPA authorities, including the specific circumstances under which institutional biosafety oversight is expected, reduced, or displaced. Without a defined relationship among NIH institutional-oversight requirements and USDA, FDA, and EPA authorities, the exclusion risks creating precisely the type of ambiguity, gap, or inconsistent oversight that federal coordination is intended to prevent.

The plant exclusion is particularly notable because it represents one of the clearest examples where the draft expands discussion of environmental risk while simultaneously excluding a major category of research capable of creating environmental consequences.

Technical Comments

The policy covers “all biohazards,” but never defines “biohazard.”

Conflicting provisions: The background repeatedly characterizes the proposal as applying to “all biohazards,” and the scope defines “research involving biohazards” through a list of covered materials. However, the definitions section contains no definition of biohazard itself.

Why it matters: Institutions cannot reliably determine the boundary of the policy, especially for materials

that present environmental, animal, plant, toxicological, or occupational risks without clearly posing a human-health risk.
The scope claims to address environmental risk while largely excluding plant hazards and plant genetic modification.
Conflicting provisions: Scope is limited to risks to human health and excludes genetically modified plants. Yet IBC responsibilities require assessing risk to the environment, policy definitions include environmental considerations, and risk-assessment provisions discuss impacts on populations and the environment.
Why it matters: A genetically modified plant with ecological or agricultural consequences appears outside scope even though the policy requires IBCs to assess environmental risks. This creates a substantive gap rather than merely an editorial issue.
“Biological agent” is defined too narrowly for how the term is used
The policy defines a biological agent as bacteria, viruses, fungi, or parasites that cause human disease. That excludes nonpathogenic organisms, animal-only pathogens, plant pathogens, and agents with uncertain pathogenicity. Yet later provisions repeatedly use “biological agent” when discussing RG1 materials, zoonotic agents, genetically modified agents, environmental impacts, and organisms not currently known to cause human disease.
Suggested correction: Define biological agent neutrally, such as bacteria, viruses, fungi, parasites, and other biologically derived or replicating entities. Define biohazardous biological agent separately based on the capacity to cause harm.
The expanded-access exemption is narrower than the reasoning appears to support
A single-patient FDA-regulated expanded-access use is excluded because it is not research, but the policy does not address analogous veterinary expanded access, compassionate use, emergency investigational use outside the exact IND terminology, or activities that involve preparation and handling by research laboratories.
The key inconsistency is between a policy scope framed around “research” and operational activities that may carry the same biosafety risks but receive different treatment based on regulatory designation.
Animal hazards are treated inconsistently
The scope covers wild-type agents only when they cause disease in humans, which appears to exclude animal-only pathogens. Nevertheless:
• “Prions and self-aggregating proteins” include materials causing disease in humans or animals.
• “Zoonotic” agents are expressly defined.
• IBC membership must include animal-containment expertise under certain circumstances.
• The policy requires reporting incidents involving covered research animals.
• Risk assessment and containment provisions address animal populations and ABSL containment.
Result: The policy regulates animal-related procedures and environmental consequences, but its threshold definition may exclude the underlying animal pathogen unless it is zoonotic or genetically modified.
Toxin scope and toxin oversight do not align
Scope covers “toxins” without an express threshold, but the definition limits toxin to a protein or peptide produced by living organisms that harms humans. Section IV-2 assigns full IBC review to Select Agent toxins, while Section IV-3 permits delegated review for non-Select Agent biological toxin proteins.
Unresolved points include:
• Whether all quantities and concentrations are covered.

• Whether inactive toxin derivatives are covered.
• Whether isolated subunits are “toxins.”
• Whether nucleic acids encoding toxins are treated as toxin research, genetic modification, or both.
• Whether low-toxicity proteins technically capable of harm require delegated IBC review.
• Why peptides are included in the definition but IV-3 refers only to “toxin proteins.”

This is a major administrative-burden issue because the literal language has no de minimis or potency threshold.

Self-aggregating proteins are treated both as a broad class and as disease-causing materials

The scope covers “prions and other self-aggregating proteins,” while the definition appears limited to misfolded proteins that self-propagate and cause neurodegenerative disease. Section IV-2 then appears to require full IBC review for all prions and other self-aggregating proteins.

Inconsistency: The scope language could capture ordinary aggregating proteins, while the definition is narrower and disease-based. The policy should specify whether the category is limited to transmissible or experimentally propagating protein agents associated with disease.

“Biomedical research” is defined partly by institutional funding status rather than scientific content

The definition first refers to research within the NIH mission, but then includes NIH-supported research and non-NIH-funded research conducted at an NIH-funded institution. This blends a scientific definition with the rule establishing policy applicability.

Why inconsistent: Whether work is “biomedical research” should ordinarily turn on the nature or purpose of the work, while whether it is subject to the policy should be addressed in the applicability section. As written, identical research could be “biomedical” at an NIH-funded institution but not at an otherwise comparable non-recipient institution.

“Laboratory research” includes clinical settings, but clinical research is treated as structurally different

The definition says laboratory research includes clinical settings within BSL/ABSL 1–4 containment facilities. Later, the policy acknowledges that clinical settings generally do not conform to laboratory BSLs.

Why inconsistent: Clinical settings are simultaneously included within a BSL-based definition and described as not conforming to BSLs. A separate definition of clinical research involving biohazards would avoid forcing clinical activity into a laboratory-containment framework.

RG1 wild-type agents are excluded, but RG1 derivatives and commonplace materials are swept back in

Section IV-3 explicitly says wild-type RG1 agents are not subject to the policy, but delegated review is required for:

• genetically modified RG1 agents;
• transgenic organisms at BSL-1/ABSL-1;
• certain plasmids;
• replication-incompetent, non-integrating viral vectors;
• well-characterized cell lines; and
• non-Select Agent toxins.

This conflicts with the stated goal of removing red tape for low-risk research. The proposal expands mandatory oversight to many routine research materials that may present no greater biosafety risk than excluded wild-type RG1 organisms. The background promises streamlining, but the operative text creates mandatory pre-initiation review and subsequent reporting of delegated approvals to the IBC.

GDMO terminology is used more broadly than the definition supplied

The policy defines gene drive but does not separately define gene drive modified organism (GDMO). It

variously refers to gene drive modified organisms, gene drive modified biological agents, and GDMOs. Why this matters: BSO appointment, ecological expertise, NIH approval, and minimum BSL-2 containment all turn on whether work qualifies as GDMO research.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The draft repeatedly states NIH intends to strengthen IBCs. However, the proposal primarily expands IBC responsibilities rather than authority, resources, training, accreditation, or institutional support.

Major Comments

The Draft Fails to Establish Institutional Parity for Biosafety Oversight

A central objective of the biosafety modernization initiative was to strengthen the institutional standing of biosafety oversight and move IBCs toward parity with Institutional Review Boards and Institutional Animal Care and Use Committees. Stakeholders repeatedly emphasized that effective biosafety oversight requires more than an expanded scope of review. It requires IBCs to have comparable institutional recognition, independence, authority, resources, and access to senior leadership.

The draft does not accomplish this objective. Although it substantially expands the responsibilities of IBCs, it does not establish the governance structures necessary to elevate them to a position comparable to IRBs and IACUCs. It does not require institutions to:

• Place the IBC within an appropriately senior institutional oversight structure;
• Provide the IBC with direct access to senior research leadership;
• Establish institutional independence or protections for IBC decision-making;
• Provide the IBC with authority to suspend or require modification of unsafe research;
• Define minimum staffing or administrative support;
• Provide resources proportionate to the expanded scope of oversight; or
• Demonstrate that biosafety oversight receives institutional support comparable to human-subject and animal-care oversight.

The same gap applies to the BSO. Responsibility for implementing an institution-wide biosafety program should be accompanied by institutional authority and standing commensurate with that responsibility. The draft assigns substantial duties to the BSO but does not require an organizational position that provides sufficient independence, access to senior leadership, authority to require corrective action, or protection from conflicts created by competing institutional priorities. For institutions with substantial or complex research programs, NIH should require that the senior biosafety official have direct access to executive research leadership and sufficient organizational stature to raise unresolved safety concerns without relying solely on intermediate reporting channels.

This omission is particularly significant because the draft increases institutional accountability, expands the range of research subject to oversight, and makes risk assessment more dependent on local biosafety expertise. A policy cannot meaningfully strengthen IBCs and BSOs while leaving their institutional status, independence, authority, and resourcing almost entirely undefined. Without enforceable expectations for institutional parity and leadership access, the draft risks creating a system in which IBCs and BSOs are accountable for a much broader program but remain structurally subordinate and inadequately empowered.

NIH should revise the policy to establish minimum institutional-governance expectations for biosafety programs, including:

1. Institutional placement and leadership access appropriate to the scope and complexity of the research program;
2. Documented authority for the IBC or BSO to immediately pause activities presenting an imminent

safety concern and authority for the IBC to require corrective action, modify approval conditions, or suspend research when necessary;
3. Independence protections for biosafety determinations;
4. Minimum qualifications and competency expectations for the senior BSO;
5. Staffing and administrative-support expectations based on program size and risk;
6. Direct escalation pathways to an identified senior institutional official with authority over the research enterprise, regardless of the title used by the institution; and
7. A requirement that Biosafety Assurances describe how the institution provides its IBC and biosafety program with authority, resources, independence, and institutional support comparable to other major research-oversight functions.

At the same time, Assurance approval should focus on demonstrated institutional capability rather than prescribe a single organizational model. Institutions vary substantially in size, research portfolio, governance structure, and access to internal expertise. NIH should define the minimum functions and authorities that must be present while permitting institutions to use shared services, qualified external expertise, consortium arrangements, and externally administered IBCs where those models provide the necessary capabilities.

Where an external or shared IBC is used, written arrangements should distinguish functions that may be performed centrally from responsibilities that require local authority, knowledge, or physical presence. These include access to facility and personnel information, inspections, local training, occupational-health coordination, incident response, urgent safety action, records, implementation of approval conditions, and enforcement.

NIH should also clarify how an institution's Assurance applies to affiliated hospitals, separately incorporated institutes, joint ventures, incubators, leased laboratories, shared core facilities, and other arrangements in which legal ownership, research sponsorship, laboratory location, personnel, and operational control do not fall within the same organizational boundary.

IBCs Were Given More Responsibilities, Not More Authority

One of the stated goals of modernization was to strengthen local biosafety oversight. However, the draft primarily increases IBC responsibilities without substantially expanding IBC authority.

The policy places significant new obligations on IBCs, including expanded protocol review, incident review, public posting of meeting minutes and incident reports, review of lower-risk incidents, maintenance of public records, and coordination of NIH approval requests. At the same time, the policy does not:

- Provide explicit enforcement authority;
- Establish mechanisms for suspending unsafe research;
- Create accreditation or certification standards;
- Provide enhanced institutional protections or independence;
- Develop standardized national training resources; or
- Provide additional funding to support these expanded responsibilities.

As written, IBCs appear to assume substantially greater workload without receiving corresponding increases in authority, resources, or institutional standing.

BSOs Remain Underdeveloped Despite Expanded Reliance on Risk Assessment

The draft repeatedly emphasizes risk assessment as the cornerstone of oversight, yet devotes relatively limited attention to the qualifications, authority, and role of BSOs.

The policy assigns BSOs responsibilities such as inspections, incident response, reporting concerns, and

technical consultation. However, it does not establish:

- Minimum qualifications;
- Competency requirements;
- Continuing education expectations;
- Certification standards;
- Staffing expectations;
- Reporting independence;
- Stop-work authority;
- Formal authority to require corrective actions; or
- Required participation in protocol approvals or incident determinations.

Further, institutions without a designated BSO may simply assign these responsibilities to another institutional official, raising questions regarding qualifications, consistency, and independence.

If NIH intends risk assessment to become the central principle of biosafety oversight, BSOs must be strengthened commensurately through national competency expectations, clearly defined authority, organizational independence, and direct access to senior institutional leadership. Assigning additional responsibilities without requiring corresponding institutional standing or authority perpetuates the very structural weakness that the modernization initiative was expected to address. NIH should establish a functional expectation that the senior biosafety official occupy a position with sufficient authority and executive access to implement institution-wide requirements, require corrective action, and elevate unresolved risks without institutional interference.

BSO appointment requirements conflict with mandatory BSO duties

A BSO must be appointed only when the institution conducts BSL-3/4 or GDMO research. If no BSO is designated, another official must perform the listed BSO responsibilities.

Inconsistency: The policy formally conditions the BSO position on certain work, but effectively requires every covered institution to assign the BSO functions to someone. It is unclear whether that alternate official must have equivalent qualifications, independence, access, authority, or institutional standing.

BSO responsibility is defined, but BSO authority is not

The BSO is responsible for inspections, reporting significant problems, incident investigation, and technical advice. The policy does not provide corresponding authority to access facilities and records, stop unsafe work, require corrective action, or elevate unresolved concerns directly to institutional leadership.

This is not simply an omission. It creates an accountability mismatch: the BSO may be held responsible for functions that the policy does not empower the BSO to carry out.

Occupational-health obligations are optional at the institutional level but operationally assigned to the PI

The institution “may” be required to establish an OHSP under other requirements or based on the research. The PI must inform staff of occupational-health or exposure-response procedures that are “advised or required.”

Inconsistency: The policy gives no trigger for when an OHSP is required under this policy, who determines that it is needed, or who develops the procedures that the PI must explain. The influenza provision later expressly requires an occupational health plan for certain work, demonstrating that the policy can provide a trigger when intended.

Facility responsibility is assigned to the PI even when facilities are institutionally managed

The PI must ensure the “integrity, maintenance, and correct functioning” of facilities, physical containment equipment, and PPE. The institution and BSO also carry programmatic and inspection

responsibilities.
Conflict: A PI may control use of equipment and reporting of defects but not building ventilation, certification contracts, capital repairs, emergency power, or institutional maintenance systems. The policy should divide responsibility among the institution, facilities owner, BSO, PI, and equipment user.
Increased Federal Involvement Appears Inconsistent with Calls for Stronger Local Oversight
Many stakeholders supported modernization because it promised a more adaptive, risk-based framework grounded in local expertise. Instead, several provisions create new NIH approval pathways involving:
• Emerging agents;
• Novel agents;
• Certain zoonotic agents;
• Containment reduction requests;
• Certain gene-drive-related activities; and
• Other cases where containment classifications are not readily established.
This creates a fundamental tension within the proposal. The policy repeatedly emphasizes the importance of institutional risk assessment while simultaneously reserving some of the most complex and consequential risk determinations for NIH review.
NIH should carefully evaluate whether these new federal review mechanisms provide sufficient additional safety benefit to justify increased review timelines, duplicated effort, and administrative burden.
The Draft Does Not Clearly Demonstrate a Reduction in Administrative Burden for Low-Risk Research
One of the primary objectives stated throughout the modernization effort was to expand oversight of higher-risk activities while simultaneously reducing unnecessary burden for low-risk research. The draft successfully broadens oversight to include many biological hazards beyond recombinant and synthetic nucleic acid technologies; however, it is less clear how the proposal reduces burden for lower-risk activities.
Several provisions may actually increase review and documentation requirements for activities historically considered low risk, including:
• Certain RG1 genetically modified organisms (e.g., commercially available ABSL-1 mice/rats);
• Transgenic organisms maintained at ABSL-1 or BSL-1;
• Certain plasmids and viral vectors;
• Well-characterized cell lines;
• Lower-risk incident reporting; and
• Expanded delegated-review documentation requirements.
At many institutions, commercially available transgenic mouse strains maintained under ABSL-1 conditions may number in the hundreds, and low-risk plasmids, routine cloning constructs, and well-characterized cell culture systems represent some of the most common research activities conducted in biomedical laboratories.
Additionally, the proposal creates new documentation, transparency, reporting, and public-record obligations that may increase administrative workload at all levels of oversight. NIH should more clearly demonstrate how the proposed framework achieves its stated goal of reducing administrative burden for low-risk activities and should consider additional exemptions, registrations, or administrative-review pathways where biosafety risk is well understood and minimal.
Delegated Review Is Not a Replacement for Exemption

Throughout the biosafety modernization initiative, NIH discussed preserving proportionate oversight mechanisms for routine, well-characterized, lower-risk research. Historically, some research activities have been exempt from NIH Guidelines registration requirements or allowed to proceed through streamlined notification pathways. Under the proposed Policy, many of these activities would instead require prospective delegated review and approval. Delegated review may be less burdensome than full committee review, but it remains a formal review and approval process.

For example, research involving commercially available ABSL-1 transgenic rodents, certain routine plasmids, specified low-risk viral vectors, genetically modified RG1 organisms, and well-characterized cell lines may require review before initiation despite presenting risks that are already well understood and routinely managed. Institutions would need to identify these activities, evaluate applicability, conduct review, document determinations, communicate approvals, track amendments, maintain records, and report delegated approvals to the IBC.

As a result, the proposal may shift substantial volumes of routine research from exemption or notification pathways into approval pathways. NIH should provide data demonstrating that the additional review creates a meaningful safety, accountability, or learning benefit and should consider whether notification, registration, or exemption pathways remain appropriate for categories of research with well-established risks and control measures.

NIH approval may be required for a very broad, potentially unintended group of unclassified agents

Conflicting provisions: IBCs must petition NIH for emerging, novel, or zoonotic biological agents when an RG classification or containment level is unavailable in the BMBL. Section IV-1 similarly requires NIH and IBC approval for such agents. At the same time, the policy says absence from the RG lists does not imply RG1 and requires an institutional risk assessment.

Why it matters: Many ordinary RG2 agents may lack an explicit BMBL agent summary or minimum containment recommendation. The text could therefore require NIH approval for routine work, even when the agent is not meaningfully “emerging,” “novel,” or “zoonotic.”

Technical Comments

Sections IV-2 and IV-3 overlap without a precedence rule.

Conflicting provisions: Section IV-2 requires full IBC review for genetically modified cells, viruses, or organisms other than plants, apparently across all risk groups. Section IV-3 permits delegated review for genetically modified RG1 agents, transgenic organisms at BSL-1/ABSL-1, certain plasmids and viral vectors, and well-characterized cell lines.

Why it matters: The same submission may qualify simultaneously for full-committee and delegated review. “Not otherwise specified in other sections” may be intended as a carve-out, but the policy never expressly says IV-3 controls over IV-2.

Delegated approval is both delegated and effectively submitted to the full committee record

Delegated reviewers may approve lower-risk work, but every approval must be reported “in full” to the IBC at its next meeting and included in the minutes. Those minutes must then be publicly posted.

Internal policy tension: Delegated review is presented as streamlining, yet it creates mandatory full reporting, minute documentation, approval of those minutes, redaction review, and public posting. The policy does not say whether the full IBC merely receives the approval or can reconsider it.

“Well-characterized cell lines” are assigned delegated review without a clear scope basis

The scope applies to cells or organisms containing covered agents or modifications, but Section IV-3 separately lists research with well-characterized cell lines.

Unclear result: A non-recombinant, well-characterized human cell line may be included under IV-3 even

when it is not known to contain a pathogen and does not independently satisfy the scope definition. Conversely, Section IV-2 requires full IBC review of primary cells that "may" contain adventitious agents. The policy needs explicit criteria distinguishing exempt cell culture, delegated review, and full review.

"Initial submissions" and "de novo" review requirements do not align cleanly

Section IV-2 says initial submissions within scope generally require IBC review. Section III-B permits approvals for no more than three years and then requires a de novo registration and review.

Unresolved question: Is a three-year de novo renewal treated as an "initial submission," thereby defaulting to full IBC review even when the research would otherwise qualify for delegated review under IV-3? The policy should expressly state whether renewal follows the same review pathway as the underlying risk category.

Continuing-Oversight Requirements Are Not Functionally Distinguished

The draft establishes multiple forms of continuing oversight, including de novo review, periodic review, inspections, modification review, incident-driven reassessment, and NIH containment determinations, but does not clearly define the distinct purpose of each activity or how information generated through one process may satisfy another. Without such distinctions, periodic review may become a second abbreviated protocol review, de novo review may repeat information already verified through inspections and modification review, and minor inspection findings or incidents may unnecessarily reopen an entire protocol.

NIH should publish a continuing-oversight matrix identifying the purpose, trigger, responsible party, minimum documentation, relationship to the existing approval period, and effect on research authorization for each process. Institutions should be permitted to reuse or verify unchanged information and to rely on findings generated through another oversight activity when those findings address the same question.

NIH should also explain the basis for applying the same three-year maximum approval period to lower-risk delegated research and higher-risk full-committee research. A predictable national minimum may be appropriate, but the incremental value and necessary depth of reassessment may differ by risk, uncertainty, research stability, inspection history, and other continuing-oversight information.

NIH determinations are described as both project-specific and generally published precedents

IBC petitions must contain experiment-specific details, including modifications, biological systems, manipulations, reagents, animal work, local containment, and the institution's risk assessment. NIH then publishes approved determinations for lower-containment research.

Unresolved issue: It is unclear whether a published NIH determination:

- applies nationally to equivalent work;
- is limited to the requesting institution;
- is limited to the named PI, facility, construct, or procedure; or
- may be relied upon by a different IBC without another NIH petition.

This directly affects whether the approval system becomes a reusable national resource or a series of duplicative case-by-case requests.

"Initial requests" implies precedent, but reliance on prior determinations is not defined

NIH reviews initial requests to lower containment for RG3/RG4 work, while full IBC review applies when NIH previously approved such work at lower containment.

The proposal implies that subsequent requests may not require new NIH review, but it never defines "previously approved," substantial equivalence, acceptable deviations, or who determines that a prior decision applies.

3. Continued utility of Risk Groups: Risk Groups remain a useful and important tool for hazard communication, institutional review, and initial characterization of biological risk. They provide a common language for communicating hazard characteristics across institutions and agencies. While Risk Groups do not fully account for experimental context, manipulations, or mitigation strategies and should not independently dictate containment or oversight decisions, they remain an effective starting point when used with agent-specific and experiment-specific risk evaluation. Institutional risk assessment should remain the foundation for determining appropriate containment and other biosafety controls.

Mandatory Requirements and Advisory Technical Guidance Must Be Distinguished

The final Policy should also clearly distinguish mandatory NIH requirements from advisory technical recommendations in the BMBL. Although the BMBL appropriately serves as a primary technical resource for protocol-specific risk assessment, it does not independently establish federal jurisdiction, institutional review requirements, or enforceable compliance obligations. Institutions therefore need to know which practices are mandatory under the Policy, which are recommended starting points, when equivalent or alternative controls may be used based on a documented risk assessment, and what documentation is expected when professional biosafety judgment supports an approach that differs from a BMBL recommendation.

Without a clear distinction, institutions may treat advisory recommendations as mandatory requirements or, conversely, may apply institutional discretion where NIH intended a binding minimum. This ambiguity directly affects containment determinations, Assurance review, and what NIH will consider noncompliance.

Lack of Training Infrastructure

The policy heavily relies on investigator, BSO, and IBC risk assessments but provides little guidance regarding how competency will be achieved or maintained.

The policy requires training but does not establish:

- National training curricula;
- Core competencies;
- Risk assessment certification programs;
- Standardized case studies;
- Continuing education requirements; or
- Federal training resources.

Modernization should include a national framework for biosafety and biorisk management training to improve consistency across institutions. This competency infrastructure should complement, rather than replace, clear assignment of institutional and investigator training responsibilities.

“Genetic modification” is expansive enough to capture conventional selection and non-biological hazard programs

The definition includes stable alterations produced through passaging, reassortment, chemical means, or radiological means.

This creates several internal tensions:

- The policy is framed as biosafety oversight of biohazards, but the definition may capture organisms altered through chemical mutagenesis or irradiation.
- Genetically modified RG1 agents require delegated review, even if the modification does not plausibly increase risk.
- An organism selected through passage could be regulated as genetically modified even without recombinant or synthetic nucleic acid manipulation.

• The definition may turn attenuation by passage into “genetic modification,” while the wild-type definition excludes organisms with deliberately introduced modifications.
Suggested correction: Distinguish deliberate genetic engineering from selection, adaptation, reassortment, induced mutagenesis, and incidental genomic change, then assign oversight based on the resulting risk rather than treating every category identically.
Mandatory BSL-2 for all GDMOs conflicts with risk-based environmental containment
All GDMOs must be conducted at a minimum of BSL-2, while the policy later recognizes geographically, environmentally, and genetically isolated settings as possible containment strategies.
This is difficult to reconcile for non-microbial organisms managed in specialized arthropod, aquatic, greenhouse, or ecological containment facilities that do not neatly map to BSL-2 laboratory design.
Influenza containment language is overbroad or grammatically ambiguous
The policy states that experiments with viruses containing genes or segments from specified strains must be conducted at BSL-3 enhanced containment. The wording does not establish whether this applies to:
• any segment;
• only segments associated with increased risk;
• a majority of the genome;
• infectious virus versus non-replicating constructs; or
• low-pathogenicity strains that share an H5 subtype but are not within the specified highly pathogenic lineage.
This is especially inconsistent with the preceding influenza rule, which uses the source of the majority of segments to determine containment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The value of voluntary adoption will depend on whether the framework is practical, scalable, understandable, and supported by sufficient resources. Institutions not legally subject to the Policy are unlikely to adopt a system that requires extensive prospective review of routine low-risk research, detailed public posting, complex incident classification, and substantial administrative infrastructure without a clear safety benefit.

NIH should allow voluntary adopters to implement the Policy through a scalable, risk-based model. Core principles and minimum program capabilities could remain consistent, while review pathways, staffing models, documentation, and governance structures are proportionate to the institution’s research portfolio. Shared or consortium IBCs, externally administered review, external biosafety expertise, mutual-aid arrangements, and standardized national tools may be especially important for smaller institutions.

Voluntary compliance would also be more attractive if NIH preserved registration, notification, and exemption pathways for predictable low-risk research rather than requiring formal approval of every covered activity. Requiring every delegated approval to be reported in full and incorporated into publicly posted minutes may discourage adoption by institutions that lack dedicated biosafety administrative personnel.

NIH should provide model policies, Assurance materials, risk-assessment tools, scope and review decision trees, standardized training, examples, shared databases, and technical-assistance resources that voluntary adopters can use without developing complete systems independently. NIH should also

consider recognition mechanisms and implementation support for institutions that voluntarily adopt the framework.

Public-disclosure requirements should be carefully calibrated. Voluntary adoption is less likely if institutions conclude that participation will require extensive disclosure of investigator identities, research details, incidents, or security-sensitive information beyond what is necessary for accountability. Standardized, de-identified public summaries and aggregate reporting would be more compatible with voluntary adoption while preserving transparency and safety learning.

Finally, NIH should distinguish voluntary compliance with the Policy from voluntary submission of near misses or other information to NBDSAC. Institutions need clear confidentiality, de-identification, access, disclosure, and non-enforcement protections before they will participate confidently in a voluntary national learning system.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: NIH should consider whether overly burdensome public-reporting requirements could discourage voluntary adoption of the framework by institutions not otherwise subject to the policy. Voluntary adoption is more likely when requirements are practical, scalable, and supported by clear guidance and shared resources. Encouraging voluntary compliance will require balancing transparency and accountability with implementation burden, confidentiality, and the need to preserve a strong reporting culture.
Public posting obligations conflict with privacy and de-identification principles.
Conflicting provisions: Institutions must post detailed IBC minutes and all incident reports publicly, subject to unspecified “appropriate and allowable” redactions. The policy separately requires NBDSAC data to be de-identified and protects voluntarily reported institutional and individual privacy.
Why it matters: The policy applies a clear de-identification standard to voluntary federal reporting but no corresponding standard to mandatory public posting. Without defined allowable redactions, institutions may either disclose too much or redact inconsistently.
Recused members may count toward quorum
The policy bars members from reviewing or approving projects in which they have a conflict, but permits them to count toward the voting quorum even when recused from the final determination.
Governance inconsistency: A quorum is ordinarily intended to ensure that a sufficient number of eligible members can deliberate and vote. Counting an ineligible member could permit approval by fewer non-conflicted members than the nominal quorum requirement suggests. The policy also does not specify the vote denominator after recusal.
Training is required but no minimum standard or responsible training authority is established
Separate from the national competency infrastructure discussed above, the policy does not clearly allocate responsibility for delivering, documenting, and verifying required training. The institution must ensure training for IBC members, BSOs, PIs, and laboratory staff, while the PI must provide or coordinate training for personnel. The policy also requires posting synopses of relevant staff training, but does not define required content, frequency, competency assessment, NIH-provided training, or documentation standards.
Result: Institutions and PIs have overlapping accountability, while neither has a defined compliance benchmark.
Assurance approval is a prerequisite, but the policy provides no transition mechanism
No covered research may be conducted until NIH approves the institution’s written Biosafety Assurance.

The policy applies to all existing awards and ongoing intramural studies six months after publication of the final policy. Assurances may be approved for up to four years.
Operational inconsistency: If NIH has not approved every recipient's assurance by the effective date, the literal text appears to halt ongoing covered research. The draft does not provide provisional assurances, deemed approval, phased implementation, or continued operation while an assurance is under review.
Record-retention periods are not mapped to record types
The policy cites a three-year federal award-record period but separately requires public posting of IBC minutes and incident reports for at least five years. It says some records may need longer retention and that records associated with awards must remain publicly available during the applicable period. It does not state the retention period for protocols, risk assessments, delegated reviews, training documentation, determinations, or assurance records.
Needed correction: A record-retention table identifying the triggering event, retention period, public-posting period, responsible custodian, and treatment of records covering multiple awards.
Incident-reporting categories overlap
Reportable categories include:
• any BSL-3/ABSL-3 or BSL-4/ABSL-4 incident;
• potential exposures involving injury or medical treatment;
• BSL-2/ABSL-2 exposures requiring agent-specific treatment;
• compliance violations at any level;
• lower-risk BSL-1/2 incidents that remain internally reportable; and
• minor spills that generally do not need reporting.
Ambiguities:
• "Any incident" at high containment is broader than the examples that follow it.
• "Basic first aid" and "agent-specific treatment" are not defined.
• A minor spill may be excluded, while another provision captures any BSL-1/2 incident.
• An animal bite or scratch must be reported to the IBC even without biohazard exposure, provided it occurred during research subject to the policy.
• A compliance violation may be reportable to NIH even if it presented no actual safety risk.
Incident Reporting Must Account for Preliminary and Evolving Information
Institutions may be required to classify an incident before medical, engineering, or investigative facts are complete. NIH should therefore define the minimum information required for the initial 24-hour notification and make clear that this notification is preliminary and need not include a completed root-cause analysis, final medical findings, or completed corrective actions. Institutions should be permitted to identify unresolved matters in the 30-day report, provide material updates as additional information becomes available, and reclassify an event in good faith as the facts develop.
NIH should also clarify how precautionary medical evaluation, diagnostic testing, observation, prophylaxis, and later medical findings affect the reporting determination. Medical consultation or prophylaxis may be provided out of an abundance of caution before the significance of an exposure is known and should not automatically determine the final incident classification.
When one event is reportable under multiple federal programs, NIH should permit a common factual investigation and core report, supplemented only by program-specific information. Federal systems should use a common event identifier or another reconciliation mechanism so that one underlying event is not treated as multiple incidents solely because it is reported to more than one program.
Public reporting may undermine the voluntary near-miss program

Lower-risk incidents must be reported internally, finalized, and publicly posted. Near-misses may also be voluntarily and confidentially submitted to NBDSAC, whose data must be de-identified.
Policy-design conflict: The federal system is designed around confidentiality and de-identification, while the institutional system requires public reports. The boundary between a mandatory "lower-risk incident" and a voluntary "near-miss, secondary failure, or procedural issue" is not defined.
The policy refers to NIH's "final response" without a response deadline
Institutions must post reportable incident information within 30 days of NIH's final response, and NIH must review and respond "in a timely manner." No defined deadline or endpoint establishes when NIH's response is final.
Result: Institutions cannot control or predict the public-posting date, and an open-ended NIH review could leave a report in provisional status indefinitely.

6. Other feedback relevant to this resource: Major Comments
Six-Month Implementation Timeline Is Unrealistic
The policy becomes effective six months after publication of the final version and appears to require approved Biosafety Assurances before research may continue.
Even institutions with mature biosafety programs will likely need to:
• Revise policies and procedures;
• Develop assurance processes;
• Build new public web infrastructure;
• Create redaction procedures;
• Modify protocol management systems;
• Develop new training materials;
• Expand protocol inventories;
• Train investigators, IBC members, and biosafety staff; and
• Establish new incident reporting workflows.
For smaller universities, hospitals, teaching institutions, and emerging research organizations, these changes may require substantial new staffing and infrastructure investments. Although NIH has issued draft templates for incident reporting and IBC meeting minutes, institutions do not yet have the full set of training resources, databases, guidance documents, risk assessment tools, assurance materials, and implementation resources needed to support this transition.
NIH should provide a minimum 24-month phased implementation period following publication of the final Policy and the foundational implementation materials necessary for compliance. Implementation milestones should be tied to the availability of final definitions, decision tools, templates, Assurance instructions, reporting systems, training materials, redaction standards, and NIH review capacity, rather than running solely from publication of the final Policy. If those materials are delayed, NIH should use defined conversion periods, grandfathering, provisional or deemed Assurance mechanisms, and other transition measures so that institutions do not lose usable implementation time or have to suspend otherwise compliant research.
NIH Should Establish Federal Review Service Standards
The draft assigns institutions numerous fixed deadlines and makes some research activities dependent on prior NIH action, but it does not establish corresponding operational expectations for federal review. NIH should publish service standards for Biosafety Assurance review, containment determinations, incident follow-up requiring federal direction, and other decisions that may delay institutional action. These standards should address submission completeness, expected review timeframes, requests for

additional information, pause-and-restart rules, written decisions, escalation pathways for delayed reviews, and the status of research when a complete and timely submission remains pending through no fault of the institution. NIH should also establish continuity procedures for a lapse in federal appropriations, government closure, system outage, or other period during which NIH is unable to act. Institutions should not be required to suspend otherwise compliant research or incur a compliance finding solely because a federal administrative review remains incomplete or NIH systems are unavailable.

NIH Should Establish a National Biosafety Determination and Risk Classification Database

The draft policy creates multiple mechanisms through which NIH may make determinations regarding containment levels, risk classifications, and lower-containment approvals. However, the policy does not describe how these determinations will be communicated to the broader research community or whether previously issued determinations may be relied upon by other institutions.

Without a centralized system, institutions may be required to repeatedly submit similar requests regarding the same organisms, experimental systems, or containment questions, resulting in duplicative effort both for institutions and NIH. This concern is particularly relevant for novel, emerging, zoonotic, or poorly characterized biological agents, where local institutions may lack access to prior federal determinations.

NIH should establish and maintain a publicly searchable database similar to Health Canada's ePathogen system that includes:

- Risk Group classifications;
- NIH containment determinations;
- Approved lower-containment decisions;
- Agent summaries;
- Relevant precedent decisions; and
- Associated guidance documents.

Such a resource would improve consistency, reduce duplication, increase transparency, and support risk-based decision making across the research enterprise.

Standardized Templates and Implementation Resources Require Further Development Prior to Implementation

The draft policy appropriately recognizes the importance of implementation support and NIH has already taken an encouraging first step by publishing draft templates for both incident reporting and IBC meeting minutes. Standardized forms have the potential to improve consistency across institutions and promote transparency regarding biosafety oversight activities.

NIH should clarify whether its templates are mandatory, recommended, or illustrative. Compliance should be based primarily on required content and performance standards rather than use of a particular document format. Many institutions already use electronic compliance-management systems that generate agendas, attendance records, voting outcomes, protocol summaries, approvals, and meeting records from structured data. Institutions should be permitted to continue using those systems and alternative formats when all required information is captured, retained, and made publicly available as required.

A minimum-content approach would promote consistency while avoiding unnecessary system modifications or manual duplication of information already maintained in institutional records. NIH should distinguish clearly between required data elements and model templates intended to assist institutions.

The current draft templates raise significant implementation concerns that should be resolved prior to policy implementation. The draft IBC meeting minutes template requires substantial documentation of protocol summaries, risk assessments, training, occupational health considerations, biosafety level determinations, committee discussions, delegated review activities, incidents, inspections, and other committee business. Similarly, the incident reporting template requires extensive documentation regarding personnel, training history, SOP compliance, occupational health considerations, corrective actions, and root cause analysis.

While transparency is an important objective, the level of detail contemplated by these templates may create substantial administrative burden for institutions and IBCs. In particular:

• The meeting-minutes template appears to require documentation of a significant portion of the committee's deliberative process and risk assessment rationale.

• The meeting-minutes template requires documentation of delegated-review approvals within publicly posted minutes, potentially reducing some of the efficiency benefits of delegated review.

• Both templates require public disclosure of information that may traditionally have been retained within institutional records rather than prepared for public consumption.

• The incident-reporting template expressly states that PI names, biological agents, grant numbers, and other information commonly available from public sources may not be redacted. While intended to increase transparency, this approach may have unintended consequences for reporting culture, personnel safety, and research security. Publicly associating named investigators and identifiable research personnel with specific biological agents, animal studies, facilities, or incidents could facilitate harassment, intimidation, targeted activism, or other threats, particularly in connection with controversial or sensitive research. The potential risks extend beyond PIs to animal care personnel, veterinarians, biosafety professionals, laboratory staff, and other employees associated with the work. The draft provides de-identification and privacy protections for information submitted to the National Biosafety Data and Safety Analysis Center but does not establish a comparable risk-based framework for publicly posted institutional incident reports. NIH should establish clear standards permitting information to be redacted when disclosure could reasonably create personnel-safety, research-security, privacy, or harassment concerns without materially advancing transparency or public-health objectives.

• The draft policy and templates do not clearly define the boundaries of allowable redaction practices, leaving institutions vulnerable to inconsistent implementation and potential disputes regarding appropriate public disclosure.

In addition, several key implementation resources are still absent. Institutions will need additional guidance and standardized tools to ensure consistent implementation, including:

• Biosafety Assurance templates;

• Comprehensive risk assessment templates and examples;

• Example completed incident reports and meeting minutes;

• Training materials for IBC members, BSOs, Investigators, and Institutional Officials;

• Guidance documents describing acceptable implementation approaches for institutions of varying size and complexity;

• Clear redaction guidance for public meeting minutes and incident reports;

• National databases for containment determinations and Risk Group classifications;

• Guidance regarding what qualifies for delegated review versus full committee review; and

• Interagency guidance clarifying relationships among NIH, USDA, CDC, FDA, EPA, OSHA, and Select Agent requirements

NIH should pilot test the proposed templates with institutions representing a range of biosafety program sizes and maturity levels before finalizing these requirements. Feedback from such pilots would help ensure that transparency objectives are achieved without creating unnecessary administrative burden or inadvertently discouraging incident reporting. Further refinement of these templates and supporting implementation resources would likely improve both consistency and long-term compliance outcomes. Institutions should be afforded an opportunity to review draft implementation materials before final policy implementation because several critical operational details appear to depend on future guidance rather than the policy text itself.

Material Revisions and Implementation Requirements Should Receive Stakeholder Review

Because several critical requirements remain undefined and may be resolved through later guidance, templates, or substantial revisions to the Policy, NIH should provide stakeholders an opportunity to review and comment on materially revised policy language and major implementation materials before they become binding. At a minimum, institutions should be able to evaluate the complete package of scope definitions, review criteria, Assurance requirements, reporting standards, public-disclosure rules, and transition procedures before implementation obligations are finalized.

Modernization Should Not Become an Unfunded Mandate

The draft policy substantially expands biosafety oversight responsibilities, increases transparency requirements, establishes new reporting obligations, and requires expanded institutional infrastructure. However, the policy does not identify corresponding funding mechanisms to support these activities. Implementation of the proposed requirements will likely require:

- Additional biosafety personnel;
- Expanded administrative support;
- Information technology infrastructure;
- Public reporting systems;
- Training development;
- Increased protocol management capacity; and
- Enhanced institutional oversight activities.

For many institutions, particularly smaller institutions, teaching-focused universities, hospitals, and emerging research organizations, these activities may represent substantial new costs.

NIH should consider mechanisms to support implementation, including:

- Dedicated biosafety supplements;
- Allowable Facilities and Administrative (F&A) recovery for biosafety activities;
- Workforce development initiatives;
- National training programs; and
- Shared implementation resources.

Expanding oversight without corresponding support may create significant implementation challenges and increase disparities between large and small institutions.

NIH Draft Policy Comments

Input on Draft NIH Biosafety Policy for Research Involving Biohazards – Individual Perspective

This letter represents my individual professional perspective based on my experience as a biosafety professional and does not necessarily represent the official position or policy of my employer. Any views, opinions, or recommendations expressed herein are my own and should not be construed as reflecting the institutional stance of my employer or its administration.

I appreciate NIH's commitment to modernizing biosafety oversight through a broader risk-based framework that reflects the realities of contemporary biological research. The draft policy successfully expands oversight beyond recombinant and synthetic nucleic acid technologies and addresses several longstanding gaps in biosafety oversight. At the same time, the draft raises important questions regarding scope, risk categorization, institutional authority, implementation feasibility, transparency, and administrative burden. The comments below are organized around the specific topics identified by NIH in the Request for Information and are intended to support the development of a practical, effective, and sustainable oversight framework.

The policy also increases transparency through public posting of Institutional Biosafety Committee (IBC) rosters, meeting minutes, incident reports, and publication of NIH incident summaries. While transparency is an important objective, several provisions may inadvertently discourage institutional reporting and limit the willingness of researchers to voluntarily share near misses and lessons learned.

However, the draft falls short of several key objectives discussed throughout the modernization effort. A recurring theme expressed during stakeholder engagement was the need to strengthen local biosafety oversight programs by empowering Institutional Biosafety Committees and Biological Safety Officers, providing standardized training and risk-assessment resources, expanding institutional authority to make risk-based decisions, and improving coordination among federal agencies.

Most significantly, the draft does not deliver on the modernization initiative’s stated objective of strengthening IBCs and moving biosafety oversight toward institutional parity with IRBs and IACUCs. Instead, it substantially increases institutional responsibilities, reporting requirements, documentation obligations, administrative workload, and compliance expectations while providing few additional authorities, resources, implementation tools, or institutional support mechanisms. It expands what IBCs and BSOs must do, but does not establish corresponding expectations for institutional standing, independence, executive access, authority, staffing, or resources. In several areas, authority appears to move away from local biosafety expertise and toward NIH review and approval processes. As a result, the policy expands oversight without proportionally strengthening the institutional infrastructure responsible for implementing that oversight. This is not a secondary implementation issue; it is a fundamental structural omission that threatens the effectiveness of the entire proposed framework.

The result is a framework that increases compliance obligations but does not fully address long-standing concerns regarding:

- IBC authority and institutional support;
- BSO qualifications, authority, independence, and staffing;
- Standardized biosafety and risk assessment training;
- National risk assessment resources and tools;
- Federal agency harmonization;
- Gaps in plant, agricultural, and environmental-risk oversight;

- The effects of mandatory public disclosure on reporting culture, privacy, personnel safety, and research security;
- Sustainable funding mechanisms for expanded oversight; and
- Implementation feasibility across institutions of varying size and maturity.

The comments below identify areas where the draft policy successfully advances the goals of biosafety modernization, as well as specific examples where it may not fully achieve the objectives discussed during stakeholder engagement. In addition, the comments highlight inconsistencies, ambiguities, definitional gaps, and potential implementation challenges that could affect clarity, consistency, and effective institutional adoption of the policy.

1. Scope of Research Covered by the Policy

Major Comments

Positive Aspects of the Draft Policy

The draft advances several important modernization goals by:

- Expanding oversight beyond recombinant and synthetic nucleic acid methodologies;
- Bringing wild-type biological agents into the oversight framework;
- Recognizing emerging technologies and novel biological risks;
- Attempting to establish more structured incident-reporting categories and timelines;
- Increasing transparency; and
- Acknowledging the need for implementation resources.

Need for Greater Interagency Harmonization

The draft frequently references other federal agencies but does not establish mechanisms for resolving overlapping jurisdictional questions or conflicting regulatory interpretations. This is particularly concerning given the continued ambiguity surrounding:

- Plant pathogens;
- Animal pathogens;
- USDA-regulated activities;
- FDA-regulated clinical activities;
- Select Agent programs; and
- Environmental release activities.

Without stronger coordination mechanisms, institutions may continue to face fragmented and inconsistent oversight requirements.

The modernization initiative appropriately seeks to broaden oversight beyond traditional recombinant DNA frameworks. However, several definitions and concepts appear to differ from terminology already used by NIH, USDA, CDC, EPA, and other federal agencies.

Examples include terminology related to:

- Novel organisms;
- Genetically engineered organisms;
- Animal pathogens;

- Plant pathogens;
- Environmental release; and
- Containment classifications.

Differences in terminology create opportunities for inconsistent interpretation and may increase regulatory burden for institutions conducting research subject to multiple federal oversight frameworks.

NIH should work with partner agencies to harmonize terminology wherever possible and publish joint guidance when differences cannot be avoided. A formal interagency biosafety coordination mechanism would further improve consistency and reduce regulatory confusion.

The Policy Does Not Address Continuity of Large-Scale Biosafety Requirements

Replacing the current NIH Guidelines also raises a significant continuity question for large-scale biosafety. Appendix K currently provides nationally recognized physical-containment and operational practices for large-scale work involving viable organisms containing recombinant or synthetic nucleic acid molecules, and BMBL Appendix M expressly refers to Appendix K as a source of practices applicable to large-scale work involving both genetically modified and non-genetically modified biological materials. The proposed Policy does not state whether Appendix K will remain effective, be incorporated into binding implementation materials, be superseded by BMBL Appendix M, or be replaced by another maintained standard.

This omission could leave institutions, production facilities, and the professionals who evaluate large-scale systems without a clear federal baseline for matters such as closed systems, transfer operations, aerosol generation, inactivation, waste handling, utilities, and process-specific engineering controls. It is also notable that the draft no longer identifies large-scale work as an independent trigger for mandatory appointment of a BSO.

NIH should identify the future status of Appendix K, the applicability of large-scale containment provisions to recombinant, genetically modified, and non-recombinant biological materials, the respective status of mandatory and advisory provisions, the qualifications and institutional expertise expected for large-scale work, and the federal entity responsible for maintaining and updating this guidance.

Other-agency oversight language could be read as either substitution or duplication

The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. It does not say whether NIH-policy oversight is displaced, deemed satisfied, or remains concurrent.

This conflicts with the later statement that clinical research cannot begin until IBC **and all other** institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight.

NIH should adopt a function-specific reliance framework rather than treating another federal program as either wholly substitutive or wholly duplicative. A federal permit, inspection, registration, accreditation, or approval may already establish particular facts concerning facilities, containment features, training, personnel qualifications, permitted activities, or required controls without resolving the entire research-specific biosafety assessment. Institutions should be permitted to incorporate and

rely upon those findings for the questions they actually address while retaining IBC responsibility for experimental features or local conditions not resolved through the other process.

NIH should publish an issue-specific crosswalk identifying potentially overlapping federal programs, the functions that may be satisfied through reliance, the documentation needed to establish reliance, the limits of that reliance, and the responsibilities that remain with the institution or IBC. This would reduce duplicative review without incorrectly treating distinct federal programs as interchangeable.

The Exclusion of Genetically Modified Plants Creates a Significant Regulatory Gap

The draft repeatedly recognizes environmental risk, unintended release, ecological impacts, environmental containment, population-level consequences, and the potential for broader environmental effects arising from biotechnology research. At the same time, genetically modified plants are expressly excluded from the scope of the policy. This exclusion is difficult to reconcile with the policy's stated objectives and risk-assessment framework.

At a minimum, genetically modified plants may present plausible food or feed safety concerns, agricultural impacts, ecological consequences, environmental persistence, gene flow, or other environmental risks that warrant institutional review and risk assessment. The draft requires IBCs to evaluate environmental risks and, in some circumstances, maintain expertise in ecological and environmental risk assessment, yet expressly excludes a major category of research capable of creating agricultural, ecological, food or feed, and other environmental consequences.

More broadly, the plant exclusion illustrates a recurring challenge throughout the draft: the absence of a clearly coordinated federal oversight framework. Federal oversight of biotechnology products is distributed principally among USDA, FDA, and EPA under the Coordinated Framework for the Regulation of Biotechnology. However, product-focused regulatory authorities do not necessarily provide continuous institutional oversight of all contained research activities preceding product development, field testing, environmental release, or commercialization. The draft does not explain whether NIH considers those product-focused authorities sufficient to replace institutional biosafety oversight during the research phase, or how occupational, containment, biosecurity, and environmental risks falling outside a defined regulatory trigger should be addressed.

If NIH intends to exclude plant research because it believes other federal agencies provide sufficient oversight, the policy should explicitly state that rationale and clearly describe where responsibility transfers from institutional biosafety oversight to other regulatory programs. As written, the policy does neither. The result is uncertainty regarding whether plant-related research falls outside oversight entirely, is expected to be reviewed under another federal framework, or remains subject to institutional review through some mechanism not described in the policy.

NIH should either incorporate appropriate oversight of genetically modified plants within the policy's scope or clearly articulate the interaction between NIH requirements and USDA, FDA, and EPA authorities, including the specific circumstances under which institutional biosafety oversight is expected, reduced, or displaced. Without a defined relationship among NIH institutional-oversight requirements and USDA, FDA, and EPA authorities, the exclusion risks creating precisely the type of ambiguity, gap, or inconsistent oversight that federal coordination is intended to prevent.

The plant exclusion is particularly notable because it represents one of the clearest examples where the draft expands discussion of environmental risk while simultaneously excluding a major category of research capable of creating environmental consequences.

Technical Comments

The policy covers "all biohazards," but never defines "biohazard."

Conflicting provisions: The background repeatedly characterizes the proposal as applying to "all biohazards," and the scope defines "research involving biohazards" through a list of covered materials. However, the definitions section contains no definition of biohazard itself.

Why it matters: Institutions cannot reliably determine the boundary of the policy, especially for materials that present environmental, animal, plant, toxicological, or occupational risks without clearly posing a human-health risk.

The scope claims to address environmental risk while largely excluding plant hazards and plant genetic modification.

Conflicting provisions: Scope is limited to risks to human health and excludes genetically modified plants. Yet IBC responsibilities require assessing risk to the environment, policy definitions include environmental considerations, and risk-assessment provisions discuss impacts on populations and the environment.

Why it matters: A genetically modified plant with ecological or agricultural consequences appears outside scope even though the policy requires IBCs to assess environmental risks. This creates a substantive gap rather than merely an editorial issue.

"Biological agent" is defined too narrowly for how the term is used

The policy defines a biological agent as bacteria, viruses, fungi, or parasites that cause human disease. That excludes nonpathogenic organisms, animal-only pathogens, plant pathogens, and agents with uncertain pathogenicity. Yet later provisions repeatedly use "biological agent" when discussing RG1 materials, zoonotic agents, genetically modified agents, environmental impacts, and organisms not currently known to cause human disease.

Suggested correction: Define *biological agent* neutrally, such as bacteria, viruses, fungi, parasites, and other biologically derived or replicating entities. Define *biohazardous biological agent* separately based on the capacity to cause harm.

The expanded-access exemption is narrower than the reasoning appears to support

A single-patient FDA-regulated expanded-access use is excluded because it is not research, but the policy does not address analogous veterinary expanded access, compassionate use, emergency investigational use outside the exact IND terminology, or activities that involve preparation and handling by research laboratories.

The key inconsistency is between a policy scope framed around "research" and operational activities that may carry the same biosafety risks but receive different treatment based on regulatory designation.

Animal hazards are treated inconsistently

The scope covers wild-type agents only when they cause disease in humans, which appears to exclude animal-only pathogens. Nevertheless:

- "Prions and self-aggregating proteins" include materials causing disease in humans **or animals**.
- "Zoonotic" agents are expressly defined.
- IBC membership must include animal-containment expertise under certain circumstances.
- The policy requires reporting incidents involving covered research animals.
- Risk assessment and containment provisions address animal populations and ABSL containment.

Result: The policy regulates animal-related procedures and environmental consequences, but its threshold definition may exclude the underlying animal pathogen unless it is zoonotic or genetically modified.

Toxin scope and toxin oversight do not align

Scope covers "toxins" without an express threshold, but the definition limits toxin to a protein or peptide produced by living organisms that harms humans. Section IV-2 assigns full IBC review to Select Agent toxins, while Section IV-3 permits delegated review for non-Select Agent biological toxin proteins.

Unresolved points include:

- Whether all quantities and concentrations are covered.
- Whether inactive toxin derivatives are covered.
- Whether isolated subunits are "toxins."
- Whether nucleic acids encoding toxins are treated as toxin research, genetic modification, or both.
- Whether low-toxicity proteins technically capable of harm require delegated IBC review.
- Why peptides are included in the definition but IV-3 refers only to "toxin proteins."

This is a major administrative-burden issue because the literal language has no de minimis or potency threshold.

Self-aggregating proteins are treated both as a broad class and as disease-causing materials

The scope covers "prions and other self-aggregating proteins," while the definition appears limited to misfolded proteins that self-propagate and cause neurodegenerative disease. Section IV-2 then appears to require full IBC review for all prions and other self-aggregating proteins.

Inconsistency: The scope language could capture ordinary aggregating proteins, while the definition is narrower and disease-based. The policy should specify whether the category is limited to transmissible or experimentally propagating protein agents associated with disease.

"Biomedical research" is defined partly by institutional funding status rather than scientific content

The definition first refers to research within the NIH mission, but then includes NIH-supported research and non-NIH-funded research conducted at an NIH-funded institution. This blends a scientific definition with the rule establishing policy applicability.

Why inconsistent: Whether work is "biomedical research" should ordinarily turn on the nature or purpose of the work, while whether it is subject to the policy should be addressed in the applicability section. As written, identical research could be "biomedical" at an NIH-funded institution but not at an otherwise comparable non-recipient institution.

"Laboratory research" includes clinical settings, but clinical research is treated as structurally different

The definition says laboratory research includes clinical settings within BSL/ABSL 1–4 containment facilities. Later, the policy acknowledges that clinical settings generally do not conform to laboratory BSLs.

Why inconsistent: Clinical settings are simultaneously included within a BSL-based definition and described as not conforming to BSLs. A separate definition of *clinical research involving biohazards* would avoid forcing clinical activity into a laboratory-containment framework.

RG1 wild-type agents are excluded, but RG1 derivatives and commonplace materials are swept back in

Section IV-3 explicitly says wild-type RG1 agents are not subject to the policy, but delegated review is required for:

- genetically modified RG1 agents;
- transgenic organisms at BSL-1/ABSL-1;
- certain plasmids;
- replication-incompetent, non-integrating viral vectors;
- well-characterized cell lines; and
- non-Select Agent toxins.

This conflicts with the stated goal of removing red tape for low-risk research. The proposal expands mandatory oversight to many routine research materials that may present no greater biosafety risk than excluded wild-type RG1 organisms. The background promises streamlining, but the operative text creates mandatory pre-initiation review and subsequent reporting of delegated approvals to the IBC.

GDMO terminology is used more broadly than the definition supplied

The policy defines *gene drive* but does not separately define **gene drive modified organism (GDMO)**. It variously refers to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Why this matters: BSO appointment, ecological expertise, NIH approval, and minimum BSL-2 containment all turn on whether work qualifies as GDMO research.

2. Structure of Tiered Oversight and Risk-Based Review

The draft repeatedly states NIH intends to strengthen IBCs. However, the proposal primarily expands IBC responsibilities rather than authority, resources, training, accreditation, or institutional support.

Major Comments

The Draft Fails to Establish Institutional Parity for Biosafety Oversight

A central objective of the biosafety modernization initiative was to strengthen the institutional standing of biosafety oversight and move IBCs toward parity with Institutional Review Boards and Institutional Animal Care and Use Committees. Stakeholders repeatedly emphasized that effective biosafety oversight requires more than an expanded scope of review. It requires IBCs to have comparable institutional recognition, independence, authority, resources, and access to senior leadership.

The draft does not accomplish this objective. Although it substantially expands the responsibilities of IBCs, it does not establish the governance structures necessary to elevate them to a position comparable to IRBs and IACUCs. It does not require institutions to:

- Place the IBC within an appropriately senior institutional oversight structure;
- Provide the IBC with direct access to senior research leadership;
- Establish institutional independence or protections for IBC decision-making;
- Provide the IBC with authority to suspend or require modification of unsafe research;
- Define minimum staffing or administrative support;
- Provide resources proportionate to the expanded scope of oversight; or
- Demonstrate that biosafety oversight receives institutional support comparable to human-subject and animal-care oversight.

The same gap applies to the BSO. Responsibility for implementing an institution-wide biosafety program should be accompanied by institutional authority and standing commensurate with that responsibility. The draft assigns substantial duties to the BSO but does not require an organizational position that provides sufficient independence, access to senior leadership, authority to require corrective action, or protection from conflicts created by competing institutional priorities. For institutions with substantial or complex research programs, NIH should require that the senior biosafety official have direct access to executive research leadership and sufficient organizational stature to raise unresolved safety concerns without relying solely on intermediate reporting channels.

This omission is particularly significant because the draft increases institutional accountability, expands the range of research subject to oversight, and makes risk assessment more dependent on local biosafety expertise. A policy cannot meaningfully strengthen IBCs and BSOs while leaving their institutional status, independence, authority, and resourcing almost entirely undefined. Without enforceable expectations for institutional parity and leadership access, the draft risks creating a system in which IBCs and BSOs are accountable for a much broader program but remain structurally subordinate and inadequately empowered.

NIH should revise the policy to establish minimum institutional-governance expectations for biosafety programs, including:

1. Institutional placement and leadership access appropriate to the scope and complexity of the research program;
2. Documented authority for the IBC or BSO to immediately pause activities presenting an imminent safety concern and authority for the IBC to require corrective action, modify approval conditions, or suspend research when necessary;
3. Independence protections for biosafety determinations;

4. Minimum qualifications and competency expectations for the senior BSO;
5. Staffing and administrative-support expectations based on program size and risk;
6. Direct escalation pathways to an identified senior institutional official with authority over the research enterprise, regardless of the title used by the institution; and
7. A requirement that Biosafety Assurances describe how the institution provides its IBC and biosafety program with authority, resources, independence, and institutional support comparable to other major research-oversight functions.

At the same time, Assurance approval should focus on demonstrated institutional capability rather than prescribe a single organizational model. Institutions vary substantially in size, research portfolio, governance structure, and access to internal expertise. NIH should define the minimum functions and authorities that must be present while permitting institutions to use shared services, qualified external expertise, consortium arrangements, and externally administered IBCs where those models provide the necessary capabilities.

Where an external or shared IBC is used, written arrangements should distinguish functions that may be performed centrally from responsibilities that require local authority, knowledge, or physical presence. These include access to facility and personnel information, inspections, local training, occupational-health coordination, incident response, urgent safety action, records, implementation of approval conditions, and enforcement.

NIH should also clarify how an institution's Assurance applies to affiliated hospitals, separately incorporated institutes, joint ventures, incubators, leased laboratories, shared core facilities, and other arrangements in which legal ownership, research sponsorship, laboratory location, personnel, and operational control do not fall within the same organizational boundary.

IBCs Were Given More Responsibilities, Not More Authority

One of the stated goals of modernization was to strengthen local biosafety oversight. However, the draft primarily increases IBC responsibilities without substantially expanding IBC authority.

The policy places significant new obligations on IBCs, including expanded protocol review, incident review, public posting of meeting minutes and incident reports, review of lower-risk incidents, maintenance of public records, and coordination of NIH approval requests. At the same time, the policy does not:

- Provide explicit enforcement authority;
- Establish mechanisms for suspending unsafe research;
- Create accreditation or certification standards;
- Provide enhanced institutional protections or independence;
- Develop standardized national training resources; or
- Provide additional funding to support these expanded responsibilities.

As written, IBCs appear to assume substantially greater workload without receiving corresponding increases in authority, resources, or institutional standing.

BSOs Remain Underdeveloped Despite Expanded Reliance on Risk Assessment

The draft repeatedly emphasizes risk assessment as the cornerstone of oversight, yet devotes relatively limited attention to the qualifications, authority, and role of BSOs.

The policy assigns BSOs responsibilities such as inspections, incident response, reporting concerns, and technical consultation. However, it does not establish:

- Minimum qualifications;
- Competency requirements;
- Continuing education expectations;
- Certification standards;
- Staffing expectations;
- Reporting independence;
- Stop-work authority;
- Formal authority to require corrective actions; or
- Required participation in protocol approvals or incident determinations.

Further, institutions without a designated BSO may simply assign these responsibilities to another institutional official, raising questions regarding qualifications, consistency, and independence.

If NIH intends risk assessment to become the central principle of biosafety oversight, BSOs must be strengthened commensurately through national competency expectations, clearly defined authority, organizational independence, and direct access to senior institutional leadership. Assigning additional responsibilities without requiring corresponding institutional standing or authority perpetuates the very structural weakness that the modernization initiative was expected to address. NIH should establish a functional expectation that the senior biosafety official occupy a position with sufficient authority and executive access to implement institution-wide requirements, require corrective action, and elevate unresolved risks without institutional interference.

BSO appointment requirements conflict with mandatory BSO duties

A BSO must be appointed only when the institution conducts BSL-3/4 or GDMO research. If no BSO is designated, another official must perform the listed BSO responsibilities.

Inconsistency: The policy formally conditions the BSO position on certain work, but effectively requires every covered institution to assign the BSO functions to someone. It is unclear whether that alternate official must have equivalent qualifications, independence, access, authority, or institutional standing.

BSO responsibility is defined, but BSO authority is not

The BSO is responsible for inspections, reporting significant problems, incident investigation, and technical advice. The policy does not provide corresponding authority to access facilities and records, stop unsafe work, require corrective action, or elevate unresolved concerns directly to institutional leadership.

This is not simply an omission. It creates an accountability mismatch: the BSO may be held responsible for functions that the policy does not empower the BSO to carry out.

Occupational-health obligations are optional at the institutional level but operationally assigned to the PI

The institution "may" be required to establish an OHSP under other requirements or based on the research. The PI must inform staff of occupational-health or exposure-response procedures that are "advised or required."

Inconsistency: The policy gives no trigger for when an OHSP is required under this policy, who determines that it is needed, or who develops the procedures that the PI must explain. The influenza provision later expressly requires an occupational health plan for certain work, demonstrating that the policy can provide a trigger when intended.

Facility responsibility is assigned to the PI even when facilities are institutionally managed

The PI must ensure the "integrity, maintenance, and correct functioning" of facilities, physical containment equipment, and PPE. The institution and BSO also carry programmatic and inspection responsibilities.

Conflict: A PI may control use of equipment and reporting of defects but not building ventilation, certification contracts, capital repairs, emergency power, or institutional maintenance systems. The policy should divide responsibility among the institution, facilities owner, BSO, PI, and equipment user.

Increased Federal Involvement Appears Inconsistent with Calls for Stronger Local Oversight

Many stakeholders supported modernization because it promised a more adaptive, risk-based framework grounded in local expertise. Instead, several provisions create new NIH approval pathways involving:

- Emerging agents;
- Novel agents;
- Certain zoonotic agents;
- Containment reduction requests;
- Certain gene-drive-related activities; and
- Other cases where containment classifications are not readily established.

This creates a fundamental tension within the proposal. The policy repeatedly emphasizes the importance of institutional risk assessment while simultaneously reserving some of the most complex and consequential risk determinations for NIH review.

NIH should carefully evaluate whether these new federal review mechanisms provide sufficient additional safety benefit to justify increased review timelines, duplicated effort, and administrative burden.

The Draft Does Not Clearly Demonstrate a Reduction in Administrative Burden for Low-Risk Research

One of the primary objectives stated throughout the modernization effort was to expand oversight of higher-risk activities while simultaneously reducing unnecessary burden for low-risk research. The draft successfully broadens oversight to include many biological hazards beyond recombinant and synthetic nucleic acid technologies; however, it is less clear how the proposal reduces burden for lower-risk activities.

Several provisions may actually increase review and documentation requirements for activities historically considered low risk, including:

- Certain RG1 genetically modified organisms (e.g., commercially available ABSL-1 mice/rats);
- Transgenic organisms maintained at ABSL-1 or BSL-1;
- Certain plasmids and viral vectors;
- Well-characterized cell lines;
- Lower-risk incident reporting; and
- Expanded delegated-review documentation requirements.

At many institutions, commercially available transgenic mouse strains maintained under ABSL-1 conditions may number in the hundreds, and low-risk plasmids, routine cloning constructs, and well-characterized cell culture systems represent some of the most common research activities conducted in biomedical laboratories.

Additionally, the proposal creates new documentation, transparency, reporting, and public-record obligations that may increase administrative workload at all levels of oversight. NIH should more clearly demonstrate how the proposed framework achieves its stated goal of reducing administrative burden for low-risk activities and should consider additional exemptions, registrations, or administrative-review pathways where biosafety risk is well understood and minimal.

Delegated Review Is Not a Replacement for Exemption

Throughout the biosafety modernization initiative, NIH discussed preserving proportionate oversight mechanisms for routine, well-characterized, lower-risk research. Historically, some research activities have been exempt from NIH Guidelines registration requirements or allowed to proceed through streamlined notification pathways. Under the proposed Policy, many of these activities would instead require prospective delegated review and approval. Delegated review may be less burdensome than full committee review, but it remains a formal review and approval process.

For example, research involving commercially available ABSL-1 transgenic rodents, certain routine plasmids, specified low-risk viral vectors, genetically modified RG1 organisms, and well-characterized cell lines may require review before initiation despite presenting risks that are already well understood and routinely managed. Institutions would need to identify these activities, evaluate applicability, conduct review, document determinations, communicate approvals, track amendments, maintain records, and report delegated approvals to the IBC.

As a result, the proposal may shift substantial volumes of routine research from exemption or notification pathways into approval pathways. NIH should provide data demonstrating that the additional review creates a meaningful safety, accountability, or learning benefit and should consider whether notification, registration, or exemption pathways remain appropriate for categories of research with well-established risks and control measures.

NIH approval may be required for a very broad, potentially unintended group of unclassified agents

Conflicting provisions: IBCs must petition NIH for emerging, novel, or zoonotic biological agents when an RG classification or containment level is unavailable in the BMBL. Section IV-1 similarly

requires NIH and IBC approval for such agents. At the same time, the policy says absence from the RG lists does not imply RG1 and requires an institutional risk assessment.

Why it matters: Many ordinary RG2 agents may lack an explicit BMBL agent summary or minimum containment recommendation. The text could therefore require NIH approval for routine work, even when the agent is not meaningfully "emerging," "novel," or "zoonotic."

Technical Comments

Sections IV-2 and IV-3 overlap without a precedence rule.

Conflicting provisions: Section IV-2 requires full IBC review for genetically modified cells, viruses, or organisms other than plants, apparently across all risk groups. Section IV-3 permits delegated review for genetically modified RG1 agents, transgenic organisms at BSL-1/ABSL-1, certain plasmids and viral vectors, and well-characterized cell lines.

Why it matters: The same submission may qualify simultaneously for full-committee and delegated review. "Not otherwise specified in other sections" may be intended as a carve-out, but the policy never expressly says IV-3 controls over IV-2.

Delegated approval is both delegated and effectively submitted to the full committee record

Delegated reviewers may approve lower-risk work, but every approval must be reported "in full" to the IBC at its next meeting and included in the minutes. Those minutes must then be publicly posted.

Internal policy tension: Delegated review is presented as streamlining, yet it creates mandatory full reporting, minute documentation, approval of those minutes, redaction review, and public posting. The policy does not say whether the full IBC merely receives the approval or can reconsider it.

"Well-characterized cell lines" are assigned delegated review without a clear scope basis

The scope applies to cells or organisms containing covered agents or modifications, but Section IV-3 separately lists research with well-characterized cell lines.

Unclear result: A non-recombinant, well-characterized human cell line may be included under IV-3 even when it is not known to contain a pathogen and does not independently satisfy the scope definition. Conversely, Section IV-2 requires full IBC review of primary cells that "may" contain adventitious agents. The policy needs explicit criteria distinguishing exempt cell culture, delegated review, and full review.

"Initial submissions" and "de novo" review requirements do not align cleanly

Section IV-2 says initial submissions within scope generally require IBC review. Section III-B permits approvals for no more than three years and then requires a de novo registration and review.

Unresolved question: Is a three-year de novo renewal treated as an "initial submission," thereby defaulting to full IBC review even when the research would otherwise qualify for delegated review under IV-3? The policy should expressly state whether renewal follows the same review pathway as the underlying risk category.

Continuing-Oversight Requirements Are Not Functionally Distinguished

The draft establishes multiple forms of continuing oversight, including de novo review, periodic review, inspections, modification review, incident-driven reassessment, and NIH containment determinations, but does not clearly define the distinct purpose of each activity or how information generated through one process may satisfy another. Without such distinctions, periodic review may become a second abbreviated protocol review, de novo review may repeat information already verified through inspections and modification review, and minor inspection findings or incidents may unnecessarily reopen an entire protocol.

NIH should publish a continuing-oversight matrix identifying the purpose, trigger, responsible party, minimum documentation, relationship to the existing approval period, and effect on research authorization for each process. Institutions should be permitted to reuse or verify unchanged information and to rely on findings generated through another oversight activity when those findings address the same question.

NIH should also explain the basis for applying the same three-year maximum approval period to lower-risk delegated research and higher-risk full-committee research. A predictable national minimum may be appropriate, but the incremental value and necessary depth of reassessment may differ by risk, uncertainty, research stability, inspection history, and other continuing-oversight information.

NIH determinations are described as both project-specific and generally published precedents

IBC petitions must contain experiment-specific details, including modifications, biological systems, manipulations, reagents, animal work, local containment, and the institution's risk assessment. NIH then publishes approved determinations for lower-containment research.

Unresolved issue: It is unclear whether a published NIH determination:

- applies nationally to equivalent work;
- is limited to the requesting institution;
- is limited to the named PI, facility, construct, or procedure; or
- may be relied upon by a different IBC without another NIH petition.

This directly affects whether the approval system becomes a reusable national resource or a series of duplicative case-by-case requests.

"Initial requests" implies precedent, but reliance on prior determinations is not defined

NIH reviews initial requests to lower containment for RG3/RG4 work, while full IBC review applies when NIH previously approved such work at lower containment.

The proposal implies that subsequent requests may not require new NIH review, but it never defines "previously approved," substantial equivalence, acceptable deviations, or who determines that a prior decision applies.

3. Risk Assessment Framework and Utility of Risk Groups

Risk Groups remain a useful and important tool for hazard communication, institutional review, and initial characterization of biological risk. They provide a common language for communicating hazard characteristics across institutions and agencies. While Risk Groups do not fully account for experimental context, manipulations, or mitigation strategies and should not independently dictate

containment or oversight decisions, they remain an effective starting point when used with agent-specific and experiment-specific risk evaluation. Institutional risk assessment should remain the foundation for determining appropriate containment and other biosafety controls.

Mandatory Requirements and Advisory Technical Guidance Must Be Distinguished

The final Policy should also clearly distinguish mandatory NIH requirements from advisory technical recommendations in the BMBL. Although the BMBL appropriately serves as a primary technical resource for protocol-specific risk assessment, it does not independently establish federal jurisdiction, institutional review requirements, or enforceable compliance obligations. Institutions therefore need to know which practices are mandatory under the Policy, which are recommended starting points, when equivalent or alternative controls may be used based on a documented risk assessment, and what documentation is expected when professional biosafety judgment supports an approach that differs from a BMBL recommendation.

Without a clear distinction, institutions may treat advisory recommendations as mandatory requirements or, conversely, may apply institutional discretion where NIH intended a binding minimum. This ambiguity directly affects containment determinations, Assurance review, and what NIH will consider noncompliance.

Lack of Training Infrastructure

The policy heavily relies on investigator, BSO, and IBC risk assessments but provides little guidance regarding how competency will be achieved or maintained.

The policy requires training but does not establish:

- National training curricula;
- Core competencies;
- Risk assessment certification programs;
- Standardized case studies;
- Continuing education requirements; or
- Federal training resources.

Modernization should include a national framework for biosafety and biorisk management training to improve consistency across institutions. This competency infrastructure should complement, rather than replace, clear assignment of institutional and investigator training responsibilities.

“Genetic modification” is expansive enough to capture conventional selection and non-biological hazard programs

The definition includes stable alterations produced through passaging, reassortment, chemical means, or radiological means.

This creates several internal tensions:

- The policy is framed as biosafety oversight of biohazards, but the definition may capture organisms altered through chemical mutagenesis or irradiation.
- Genetically modified RG1 agents require delegated review, even if the modification does not plausibly increase risk.

- An organism selected through passage could be regulated as genetically modified even without recombinant or synthetic nucleic acid manipulation.
- The definition may turn attenuation by passage into "genetic modification," while the wild-type definition excludes organisms with deliberately introduced modifications.

Suggested correction: Distinguish deliberate genetic engineering from selection, adaptation, reassortment, induced mutagenesis, and incidental genomic change, then assign oversight based on the resulting risk rather than treating every category identically.

Mandatory BSL-2 for all GDMOs conflicts with risk-based environmental containment

All GDMOs must be conducted at a minimum of BSL-2, while the policy later recognizes geographically, environmentally, and genetically isolated settings as possible containment strategies.

This is difficult to reconcile for non-microbial organisms managed in specialized arthropod, aquatic, greenhouse, or ecological containment facilities that do not neatly map to BSL-2 laboratory design.

Influenza containment language is overbroad or grammatically ambiguous

The policy states that experiments with viruses containing genes or segments from specified strains must be conducted at BSL-3 enhanced containment. The wording does not establish whether this applies to:

- any segment;
- only segments associated with increased risk;
- a majority of the genome;
- infectious virus versus non-replicating constructs; or
- low-pathogenicity strains that share an H5 subtype but are not within the specified highly pathogenic lineage.

This is especially inconsistent with the preceding influenza rule, which uses the source of the **majority of segments** to determine containment.

4. Compliance, Enforcement, and Transparency

NIH should consider whether overly burdensome public-reporting requirements could discourage voluntary adoption of the framework by institutions not otherwise subject to the policy. Voluntary adoption is more likely when requirements are practical, scalable, and supported by clear guidance and shared resources. Encouraging voluntary compliance will require balancing transparency and accountability with implementation burden, confidentiality, and the need to preserve a strong reporting culture.

Public posting obligations conflict with privacy and de-identification principles.

Conflicting provisions: Institutions must post detailed IBC minutes and all incident reports publicly, subject to unspecified "appropriate and allowable" redactions. The policy separately requires NBDSAC data to be de-identified and protects voluntarily reported institutional and individual privacy.

Why it matters: The policy applies a clear de-identification standard to voluntary federal reporting but no corresponding standard to mandatory public posting. Without defined allowable redactions, institutions may either disclose too much or redact inconsistently.

Recused members may count toward quorum

The policy bars members from reviewing or approving projects in which they have a conflict, but permits them to count toward the voting quorum even when recused from the final determination.

Governance inconsistency: A quorum is ordinarily intended to ensure that a sufficient number of eligible members can deliberate and vote. Counting an ineligible member could permit approval by fewer non-conflicted members than the nominal quorum requirement suggests. The policy also does not specify the vote denominator after recusal.

Training is required but no minimum standard or responsible training authority is established

Separate from the national competency infrastructure discussed above, the policy does not clearly allocate responsibility for delivering, documenting, and verifying required training. The institution must ensure training for IBC members, BSOs, PIs, and laboratory staff, while the PI must provide or coordinate training for personnel. The policy also requires posting synopses of relevant staff training, but does not define required content, frequency, competency assessment, NIH-provided training, or documentation standards.

Result: Institutions and PIs have overlapping accountability, while neither has a defined compliance benchmark.

Assurance approval is a prerequisite, but the policy provides no transition mechanism

No covered research may be conducted until NIH approves the institution's written Biosafety Assurance. The policy applies to all existing awards and ongoing intramural studies six months after publication of the final policy. Assurances may be approved for up to four years.

Operational inconsistency: If NIH has not approved every recipient's assurance by the effective date, the literal text appears to halt ongoing covered research. The draft does not provide provisional assurances, deemed approval, phased implementation, or continued operation while an assurance is under review.

Record-retention periods are not mapped to record types

The policy cites a three-year federal award-record period but separately requires public posting of IBC minutes and incident reports for at least five years. It says some records may need longer retention and that records associated with awards must remain publicly available during the applicable period. It does not state the retention period for protocols, risk assessments, delegated reviews, training documentation, determinations, or assurance records.

Needed correction: A record-retention table identifying the triggering event, retention period, public-posting period, responsible custodian, and treatment of records covering multiple awards.

Incident-reporting categories overlap

Reportable categories include:

- any BSL-3/ABSL-3 or BSL-4/ABSL-4 incident;
- potential exposures involving injury or medical treatment;
- BSL-2/ABSL-2 exposures requiring agent-specific treatment;
- compliance violations at any level;
- lower-risk BSL-1/2 incidents that remain internally reportable; and
- minor spills that generally do not need reporting.

Ambiguities:

- "Any incident" at high containment is broader than the examples that follow it.
- "Basic first aid" and "agent-specific treatment" are not defined.
- A minor spill may be excluded, while another provision captures any BSL-1/2 incident.
- An animal bite or scratch must be reported to the IBC even without biohazard exposure, provided it occurred during research subject to the policy.
- A compliance violation may be reportable to NIH even if it presented no actual safety risk.

Incident Reporting Must Account for Preliminary and Evolving Information

Institutions may be required to classify an incident before medical, engineering, or investigative facts are complete. NIH should therefore define the minimum information required for the initial 24-hour notification and make clear that this notification is preliminary and need not include a completed root-cause analysis, final medical findings, or completed corrective actions. Institutions should be permitted to identify unresolved matters in the 30-day report, provide material updates as additional information becomes available, and reclassify an event in good faith as the facts develop.

NIH should also clarify how precautionary medical evaluation, diagnostic testing, observation, prophylaxis, and later medical findings affect the reporting determination. Medical consultation or prophylaxis may be provided out of an abundance of caution before the significance of an exposure is known and should not automatically determine the final incident classification.

When one event is reportable under multiple federal programs, NIH should permit a common factual investigation and core report, supplemented only by program-specific information. Federal systems should use a common event identifier or another reconciliation mechanism so that one underlying event is not treated as multiple incidents solely because it is reported to more than one program.

Public reporting may undermine the voluntary near-miss program

Lower-risk incidents must be reported internally, finalized, and publicly posted. Near-misses may also be voluntarily and confidentially submitted to NBDSAC, whose data must be de-identified.

Policy-design conflict: The federal system is designed around confidentiality and de-identification, while the institutional system requires public reports. The boundary between a mandatory "lower-risk incident" and a voluntary "near-miss, secondary failure, or procedural issue" is not defined.

The policy refers to NIH's "final response" without a response deadline

Institutions must post reportable incident information within 30 days of NIH's final response, and NIH must review and respond "in a timely manner." No defined deadline or endpoint establishes when NIH's response is final.

Result: Institutions cannot control or predict the public-posting date, and an open-ended NIH review could leave a report in provisional status indefinitely.

5. Implementation Resources and Guidance Needs

Major Comments

Six-Month Implementation Timeline Is Unrealistic

The policy becomes effective six months after publication of the final version and appears to require approved Biosafety Assurances before research may continue.

Even institutions with mature biosafety programs will likely need to:

- Revise policies and procedures;
- Develop assurance processes;
- Build new public web infrastructure;
- Create redaction procedures;
- Modify protocol management systems;
- Develop new training materials;
- Expand protocol inventories;
- Train investigators, IBC members, and biosafety staff; and
- Establish new incident reporting workflows.

For smaller universities, hospitals, teaching institutions, and emerging research organizations, these changes may require substantial new staffing and infrastructure investments. Although NIH has issued draft templates for incident reporting and IBC meeting minutes, institutions do not yet have the full set of training resources, databases, guidance documents, risk assessment tools, assurance materials, and implementation resources needed to support this transition.

NIH should provide a minimum 24-month phased implementation period following publication of the final Policy and the foundational implementation materials necessary for compliance. Implementation milestones should be tied to the availability of final definitions, decision tools, templates, Assurance instructions, reporting systems, training materials, redaction standards, and NIH review capacity, rather than running solely from publication of the final Policy. If those materials are delayed, NIH should use defined conversion periods, grandfathering, provisional or deemed Assurance mechanisms, and other transition measures so that institutions do not lose usable implementation time or have to suspend otherwise compliant research.

NIH Should Establish Federal Review Service Standards

The draft assigns institutions numerous fixed deadlines and makes some research activities dependent on prior NIH action, but it does not establish corresponding operational expectations for federal review. NIH should publish service standards for Biosafety Assurance review, containment determinations, incident follow-up requiring federal direction, and other decisions that may delay institutional action.

These standards should address submission completeness, expected review timeframes, requests for additional information, pause-and-restart rules, written decisions, escalation pathways for delayed reviews, and the status of research when a complete and timely submission remains pending through

no fault of the institution. NIH should also establish continuity procedures for a lapse in federal appropriations, government closure, system outage, or other period during which NIH is unable to act.

Institutions should not be required to suspend otherwise compliant research or incur a compliance finding solely because a federal administrative review remains incomplete or NIH systems are unavailable.

NIH Should Establish a National Biosafety Determination and Risk Classification Database

The draft policy creates multiple mechanisms through which NIH may make determinations regarding containment levels, risk classifications, and lower-containment approvals. However, the policy does not describe how these determinations will be communicated to the broader research community or whether previously issued determinations may be relied upon by other institutions.

Without a centralized system, institutions may be required to repeatedly submit similar requests regarding the same organisms, experimental systems, or containment questions, resulting in duplicative effort both for institutions and NIH. This concern is particularly relevant for novel, emerging, zoonotic, or poorly characterized biological agents, where local institutions may lack access to prior federal determinations.

NIH should establish and maintain a publicly searchable database similar to Health Canada's ePathogen system that includes:

- Risk Group classifications;
- NIH containment determinations;
- Approved lower-containment decisions;
- Agent summaries;
- Relevant precedent decisions; and
- Associated guidance documents.

Such a resource would improve consistency, reduce duplication, increase transparency, and support risk-based decision making across the research enterprise.

Standardized Templates and Implementation Resources Require Further Development Prior to Implementation

The draft policy appropriately recognizes the importance of implementation support and NIH has already taken an encouraging first step by publishing draft templates for both incident reporting and IBC meeting minutes. Standardized forms have the potential to improve consistency across institutions and promote transparency regarding biosafety oversight activities.

NIH should clarify whether its templates are mandatory, recommended, or illustrative. Compliance should be based primarily on required content and performance standards rather than use of a particular document format. Many institutions already use electronic compliance-management systems that generate agendas, attendance records, voting outcomes, protocol summaries, approvals, and meeting records from structured data. Institutions should be permitted to continue using those systems and alternative formats when all required information is captured, retained, and made publicly available as required.

A minimum-content approach would promote consistency while avoiding unnecessary system modifications or manual duplication of information already maintained in institutional records. NIH should distinguish clearly between required data elements and model templates intended to assist institutions.

The current draft templates raise significant implementation concerns that should be resolved prior to policy implementation. The draft IBC meeting minutes template requires substantial documentation of protocol summaries, risk assessments, training, occupational health considerations, biosafety level determinations, committee discussions, delegated review activities, incidents, inspections, and other committee business. Similarly, the incident reporting template requires extensive documentation regarding personnel, training history, SOP compliance, occupational health considerations, corrective actions, and root cause analysis.

While transparency is an important objective, the level of detail contemplated by these templates may create substantial administrative burden for institutions and IBCs. In particular:

- The meeting-minutes template appears to require documentation of a significant portion of the committee's deliberative process and risk assessment rationale.
- The meeting-minutes template requires documentation of delegated-review approvals within publicly posted minutes, potentially reducing some of the efficiency benefits of delegated review.
- Both templates require public disclosure of information that may traditionally have been retained within institutional records rather than prepared for public consumption.
- The incident-reporting template expressly states that PI names, biological agents, grant numbers, and other information commonly available from public sources may not be redacted. While intended to increase transparency, this approach may have unintended consequences for reporting culture, personnel safety, and research security. Publicly associating named investigators and identifiable research personnel with specific biological agents, animal studies, facilities, or incidents could facilitate harassment, intimidation, targeted activism, or other threats, particularly in connection with controversial or sensitive research. The potential risks extend beyond PIs to animal care personnel, veterinarians, biosafety professionals, laboratory staff, and other employees associated with the work. The draft provides de-identification and privacy protections for information submitted to the National Biosafety Data and Safety Analysis Center but does not establish a comparable risk-based framework for publicly posted institutional incident reports. NIH should establish clear standards permitting information to be redacted when disclosure could reasonably create personnel-safety, research-security, privacy, or harassment concerns without materially advancing transparency or public-health objectives.
- The draft policy and templates do not clearly define the boundaries of allowable redaction practices, leaving institutions vulnerable to inconsistent implementation and potential disputes regarding appropriate public disclosure.

In addition, several key implementation resources are still absent. Institutions will need additional guidance and standardized tools to ensure consistent implementation, including:

- Biosafety Assurance templates;
- Comprehensive risk assessment templates and examples;
- Example completed incident reports and meeting minutes;
- Training materials for IBC members, BSOs, Investigators, and Institutional Officials;

- Guidance documents describing acceptable implementation approaches for institutions of varying size and complexity;
- Clear redaction guidance for public meeting minutes and incident reports;
- National databases for containment determinations and Risk Group classifications;
- Guidance regarding what qualifies for delegated review versus full committee review; and
- Interagency guidance clarifying relationships among NIH, USDA, CDC, FDA, EPA, OSHA, and Select Agent requirements

NIH should pilot test the proposed templates with institutions representing a range of biosafety program sizes and maturity levels before finalizing these requirements. Feedback from such pilots would help ensure that transparency objectives are achieved without creating unnecessary administrative burden or inadvertently discouraging incident reporting. Further refinement of these templates and supporting implementation resources would likely improve both consistency and long-term compliance outcomes. Institutions should be afforded an opportunity to review draft implementation materials before final policy implementation because several critical operational details appear to depend on future guidance rather than the policy text itself.

Material Revisions and Implementation Requirements Should Receive Stakeholder Review

Because several critical requirements remain undefined and may be resolved through later guidance, templates, or substantial revisions to the Policy, NIH should provide stakeholders an opportunity to review and comment on materially revised policy language and major implementation materials before they become binding. At a minimum, institutions should be able to evaluate the complete package of scope definitions, review criteria, Assurance requirements, reporting standards, public-disclosure rules, and transition procedures before implementation obligations are finalized.

Modernization Should Not Become an Unfunded Mandate

The draft policy substantially expands biosafety oversight responsibilities, increases transparency requirements, establishes new reporting obligations, and requires expanded institutional infrastructure. However, the policy does not identify corresponding funding mechanisms to support these activities.

Implementation of the proposed requirements will likely require:

- Additional biosafety personnel;
- Expanded administrative support;
- Information technology infrastructure;
- Public reporting systems;
- Training development;
- Increased protocol management capacity; and
- Enhanced institutional oversight activities.

For many institutions, particularly smaller institutions, teaching-focused universities, hospitals, and emerging research organizations, these activities may represent substantial new costs.

NIH should consider mechanisms to support implementation, including:

- Dedicated biosafety supplements;

- Allowable Facilities and Administrative (F&A) recovery for biosafety activities;
- Workforce development initiatives;
- National training programs; and
- Shared implementation resources.

Expanding oversight without corresponding support may create significant implementation challenges and increase disparities between large and small institutions.

Conclusion

The draft successfully expands biosafety oversight to address modern biological risks, but it does not achieve one of the modernization initiative's most important objectives: elevating biosafety oversight to an institutional position comparable to human-subject and animal-care oversight. IBCs and BSOs are assigned substantially greater responsibilities without proportional authority, independence, institutional standing, leadership access, staffing, or resources. The draft also leaves significant gaps and ambiguities concerning plant and environmental risks, interagency coordination, low-risk research, incident reporting, public disclosure, and implementation. Absent enforceable institutional expectations and adequate implementation support, the policy risks creating greater accountability without providing the infrastructure necessary to meet it. Modernization should not merely enlarge the biosafety compliance function. It should establish IBCs and qualified biosafety professionals as empowered, appropriately supported, and institutionally recognized pillars of research oversight within a coordinated, risk-based, and sustainable federal framework.

Sincerely,

Megan Shoff, PhD, RBP, CSP

SUBJECT: Joint Transmittal of UMB and UMD Institutional Biosafety Committee Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Dear Members of the NIH Office of Science Policy:

On behalf of the joint research enterprise at the University of Maryland, Baltimore (UMB) and the University of Maryland, College Park (UMD), I submit our institutional responses to the **Draft NIH Biosafety Policy for Research Involving Biohazards.** Transmitted with this letter are reports authored independently by the Institutional Biosafety Committee (IBC) leadership and Environmental Health and Safety biosafety teams from both campuses. As summarized below and expanded in the attached submissions, our two institutions have serious concerns about the proposed regulatory framework's operational and administrative feasibility.

- **Unnecessary Administrative Burden vs. Risk Calibration:** We have deep concern that replacing the NIH Guidelines with mandatory, standardized oversight across all biohazards would create an unsustainable burden for PIs, biosafety officers, and committee members without delivering a proportionate improvement in safety.
- **Disproportionate Oversight of Low-Risk Research:** We strongly urge the NIH to retain exemptions for low-risk research activities. Eliminating these exemptions would inundate the oversight committees with hundreds of low-hazard filings, diverting critical resources away from higher-consequence biohazards.
- **Inflexible Three-Year De Novo Reviews:** Mandating that protocols be closed and resubmitted *de novo* every three years introduces unnecessary disruption for investigators.
- **Protection of Investigator Privacy & Incident Transparency:** Accelerated public disclosure of meeting minutes and mandatory inclusion of personal investigator details in incident reports create significant personal security and harassment risks for researchers. Furthermore, publicizing detailed incident reports risks establishing a punitive climate that would disincentivize transparent, voluntary reporting.
- **Governance Flexibility & Timeline Extension:** As leading research universities, UMB and UMD need institutional authority and autonomy to adapt their oversight procedures to local context. Both campuses emphasize that the proposed six-month implementation window is impractical and respectfully request an extension to at least one year to allow adequate time for PI training and systems reconfiguration.

Our institutions are happy to work collaboratively with the NIH to establish a balanced, risk-calibrated biosafety policy that protects researchers and the public while maintaining scientific progress.

Sincerely,

[redacted]

Vice President and Chief Research Officer

Section / item	Comment	Suggested change
Entire Document	The draft Policy leaves several aspects of institutional biosafety governance and implementation incompletely defined.	Clarify the minimum requirements while allowing institutions appropriate authority and flexibility to establish policies, assign responsibilities, and address matters not explicitly covered by the Policy based on their institutional needs and risk assessments.
Entire Document - Omission	The draft policy does not address the use of AI in developing biological agents.	Add guidelines for the use of AI in developing biological agents (viruses, recombinant molecules). Language on how to approach biological agents generated by AI should be added.
Other Comments	The Policy relies heavily on headings and bullet points, making specific provisions difficult to cite and cross-reference consistently	Adopt a consistent hierarchical numbering system and assign each substantive requirement a stable, unique citation identifier (e.g., III.B.2.a.(1))
Section II - General definitions	The definition of toxins is limited to proteins and peptides, excluding other types of biologically derived toxins, such as glycosides, alkaloids, and lipopolysaccharides.	Clarify whether the definition is intentionally limited to protein and peptide toxins for the purposes of this policy, or should be expanded to include other types of toxins.
Section II - Scope	The draft defines biohazards primarily in terms of risks to human health, which may exclude biological agents that pose significant risks to animal health, plant health, agriculture, or the environment. This may create gaps compared with the current NIH Guidelines.	Clarify whether animal, plant, agricultural, and environmental biohazards are within the scope of the Policy. If they are intentionally excluded, clearly state this and explain how the existing plant and environmental biosafety provisions of the NIH Guidelines will be addressed under the new framework.
Section II - Scope	The inclusion of “clinical settings” within laboratory research creates uncertainty as to whether routine collection of human biospecimens for research, such as venipuncture, requires IBC oversight even when no biohazard is manipulated or administered.	Clarify that routine clinical specimen collection alone does not require IBC review solely because specimens are collected for research. Subsequent handling or manipulation of the specimens should be evaluated separately based on the associated biosafety risk.
Section II - Scope	The definition of “biomedical research in laboratory settings” does not clearly address biosafety-relevant field research or non-research biological activities, such as teaching laboratories in academic institutions. This may create both gaps in oversight and unnecessary expansion of IBC	Clarify whether biosafety-relevant field research and non-research biological activities, such as teaching laboratories, are within the scope of the Policy. Clearly define the applicable scope and criteria so institutions can consistently determine which activities are subject to Policy requirements.
Section II - Scope	The proposed six-month implementation period may be insufficient given the substantial changes in institutional responsibilities, oversight processes, training, procedures, and compliance systems required by the new Policy.	Provide at least 12 months between publication of the final Policy and its effective date to allow institutions sufficient time for effective implementation.
Section II - Scope	The draft policy does not clearly address oversight of plant genetic modification research.	Clarify whether and how plant genetic modification research is covered under the policy.
Section III-A - Responsibilities of the Institution	The Policy does not clearly define its expectations for an Occupational Health and Safety Program (OHSP) or how it should relate to an institution’s existing occupational health and safety program.	Clarify whether an existing institutional Occupational Health and Safety Program that covers the applicable hazards satisfies the Policy, or whether a separate Policy-specific program or plan is required. If additional requirements apply to research subject to the Policy, clearly define the minimum expectations for the OHSP.
Section III-A - Responsibilities of the Institution	The Policy references an “IBC Contact” but does not define the role or its responsibilities in supporting IBC administration and compliance.	Clarify the role and responsibilities of the IBC Contact and whether institutions have flexibility to assign these administrative functions based on their organizational structure.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The statement that minor spills of low-risk agents “generally do not need to be reported” does not specify whether this refers to reporting to NIH, the IBC, or both.	Clarify the applicable reporting level and distinguish between institutional/IBC reporting and external reporting to NIH.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The expectation to include or have access to an individual knowledgeable in “community attitudes” appears to overlap with the required unaffiliated IBC members, who are specifically appointed to represent the interests of the surrounding community.	Clarify whether the required unaffiliated community members satisfy the “community attitudes” expectation, or whether NIH intends this to represent a separate area of expertise requiring an additional member or ad hoc consultant.

Section / item	Comment	Suggested change
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft defines the BSO primarily through operational and technical duties and does not adequately describe the BSO's broader role, authority, or oversight responsibilities within institutional biosafety governance. It is also unclear whether the listed BSO duties must be performed personally by the designated BSO or may be delegated to qualified biosafety personnel.	Define the BSO as the institution's designated biosafety professional responsible for leading or administering the biosafety program and providing technical oversight. Clearly establish the BSO's authority to identify, assess, communicate, and escalate biosafety concerns. Clarify that appropriate duties may be delegated to qualified biosafety personnel, such as Assistant or Associate BSOs or Biosafety Specialists.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The proposed review pathways may not consistently reflect relative risk. Primary cells that may contain adventitious agents require full IBC review, while research involving known RG2 wild-type biological agents is eligible for delegated review.	Require full IBC review for deliberate propagation or manipulation of known RG2 wild-type biological agents. Allow primary cells with potential adventitious agents to undergo delegated review when appropriate, with escalation to full IBC review based on the specific hazards and experimental procedures.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required.	Approval should be granted for a period not to exceed four years, at which time a de novo registration submission and review is required.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Petitioning NIH for determination of the minimum biocontainment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available in the BMBL.	Petitioning NIH for determination of the minimum biocontainment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available in the most current version of the BMBL.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Petitioning NIH for determination of the minimum biocontainment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available in the BMBL.	Envirnomental isolates can be kept in secure cryogenic storage but not actively utilized until authorized.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Any incidents involving exposures at BSL-2/ABSL-2 that require agent-specific treatment beyond basic first aid; and	Completely remove this section for BSL-2 as the BSL-2 risk assessment and definition mean that there is no risk to the community.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The requirement for de novo registration and review every three years creates an unnecessary administrative burden for ongoing research projects.	Allow periodic renewal of existing IBC registrations without requiring de novo registration and review.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft policy does not clearly define the authority of the IBC and BSO to suspend research in cases of noncompliance.	Clarify the authority of the IBC and BSO to suspend research when violations of the NIH Biosafety Policy occur.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	"No member of the IBC may be involved in the review or approval of a project in which they are or expect to be engaged, or in which they have a direct financial or any other conflict of interest, except to provide information requested by the IBC to facilitate their review. Such members can be counted for purposes of establishing a voting quorum for the meeting even if they recuse themselves from the final determination related to the project."	Provide further definition of engagement -> What is the threshold for engagement? For example, if an IBC member works in or is affliated with a core facility that a researcher will (or might) eventually use for the project, is the IBC member considered "engaged"?
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	"Approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required." - For a large institution that might have a 4 year review process reducing the approval time will incur a larger review burden on IBC committees.	If this is a reduction in the timeframe from existing, maybe for lower risk work that is unlikely to change, keep current rules to avoid overburdening IBC committees, particularly at large institutions
Section III-C - Responsibilities of the Principal Investigator (PI)	Research with primary cells that may be contaminated by adventitious agents.	Research with primary cells or tissues that may be contaminated by adventitious agents.
Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	Sections IV-2 and IV-3 appear to overlap for genetically modified research, creating uncertainty as to when full IBC review versus delegated review is required.	Clarify the relationship and precedence between Sections IV-2 and IV-3 and provide clear criteria for determining when genetically modified cells, viruses, or organisms qualify for delegated review rather than full IBC review.
Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	Section IV-3 requires prior delegated review and approval for a broad range of lower-risk activities. For well-defined minimal-risk research, mandatory prior approval may create administrative burden disproportionate to the biosafety risk.	Allow defined minimal-risk activities within Section IV-3 to proceed through notification or registration without prior approval. Institutions should retain flexibility to screen these activities and elevate them to delegated or full IBC review when additional risk factors are identified.
Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	The delegated review of low-risk work (BSL-1) does not seem necessary and an exemption for such review should be maintained	Maintain exemptions from IBC review for qualifying low-risk (BSL-1) research activities.

Section / item	Comment	Suggested change
Section V - Risk Assessment and Mitigation for Research Involving Biohazards	The draft policy does not provide a standardized risk assessment template to support consistent implementation across institutions.	Provide a recommended risk assessment template to promote consistency while allowing institutional flexibility.
Section V-D - Requirements and Considerations for Risk Assessment of Manipulations of Biohazards	The Policy identifies “large culture volumes” as a factor that may increase risk but does not define what constitutes a large volume or when additional large-scale risk assessment is expected.	Define a threshold or clear criteria for identifying large-volume culture research. Exceeding the threshold should trigger additional risk assessment, rather than automatically requiring a higher BSL, with containment determined based on volume together with the agent, concentration, aerosol potential, system design, and other relevant risk factors.
Section V-E - Risk Mitigation Strategies and Laboratory Containment	The draft requires BSL-3 enhanced containment and an occupational health plan for specified influenza research but does not define the minimum requirements for either or clarify whether a separate influenza-specific occupational health plan is required.	Define the minimum requirements for BSL-3 enhanced containment and the occupational health plan required for the specified influenza research, or directly reference applicable implementation guidance that defines these requirements
Part 1. Institutional Information	The draft allows the PI’s name to be included in incident reports while excluding other personally identifiable information. Identifying the PI may unnecessarily associate an individual with an incident and detract from a learning-focused, non-punitive reporting process.	Do not include the names of the PI or other individuals involved in incident reports. Incident reports should focus on the incident itself, including what occurred, contributing factors, and corrective actions, rather than identifying individuals.
Other Comments	The meeting minutes template does not clearly distinguish among full IBC review, delegated review, and periodic/renewal review. If a notification/registration-only category is adopted, this should also be reflected in the template	Add separate or clearly identified categories for full IBC review, delegated review, and notification/registration-only activities, with documentation proportional to the level of oversight. Clarify that periodic/three-year reviews may use the same format as new registrations if they are conducted as de novo reviews.
	The IBC Minutes Template unnecessarily involved and could be shortened without losing relevant information and transparency.	Simplify the IBC Minutes Template to reduce administrative burden
	The requirement to publicly post full IBC meeting minutes creates unnecessary administrative burden related to redactions and raises potential privacy and security concerns.	Allow a standardized meeting summary with essential information, such as attendance, protocol reviews and approvals, and key policy discussions, to be publicly posted instead of full meeting minutes.

Section / item	Comment	Suggested change
Section II - Scope	Toxins included in scope of the policy. 1) Toxins are of biological origin, but by their function, they are better classified as chemical agents and have Safety Data Sheets outlining precautions. The IBC would need chemical safety (different) expertise to do an appropriate risk assessment beyond the SDS. One example: Toxins are defined as "a protein or peptide produced by living organisms that causes harm in humans." That broad definition would include snake venom, which would be beyond the expertise of microbiologists. 2) As toxins are a frequent reagent, we expect somewhere around 30-200 PIs to now have to submit for this work, many of whom may not have had to write a protocol before.	Remove toxins from scope, they are better classified as chemical reagents.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	"Approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required." 1) Closing a protocol and reopening a new one creates logistical challenges in the online CICERO system, especially for IRB-connected IBC protocols. This relationship includes built-in features, including approval blocks, which would be difficult when the parent IRB protocol is not closing and reopening. 2) Many PIs are going to copy and paste, so while the intentions of forcing a protocol to close and reopen might be good, it is a large administrative burden with no real payoff.	1) Eliminate the three year closure and de novo submission requirement, 2) Allow a protocol to remain open, but require it to be re-reviewed (by FCR if appropriate) every three years, or 3) Exempt IRB-connected studies from the three-year closure requirement.
Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	"The BSO's duties include conducting periodic inspections to ensure that laboratory biocontainment facilities and equipment are functioning properly, biosafety standards are rigorously followed, and IBC approval conditions for the conduct of research are being followed." 1) It is unclear how often these inspections must occur (e.g., once in the three year life cycle or annual). 2) With the expanded scope, these inspections may involve low risk protocols, including purchasing trangenic rodents, where general lab safety or IACUC inspections are already sufficient. 3) For IRB-related IBC protocols, the location is often multiple clinics and/or hospitals. It is unclear what the expectation would be for inspecting off-campus clinical areas. The IBC has reviewed protocols in Mali and Nigeria, which would be logistically challenging to inspect. Note: this concern would also be relevent for additional types of off-campus field work. 4) The UMB Office of Animal Welfare Assurance has three FTE dedicated to Post Approval Monitoring (PAM) inspections. PAM inspections would be added to biosafety staff in additional to their other responsibilities. There is concern about the level of staffing needed, especially considering other increases in workload related to this policy. 5) It is unclear if a safety inspection can adequately verify equipment functionality.	Make inspections recommended and based on a risk assessment.

Section / item	Comment	Suggested change
Section IV-1 - Research That Requires NIH and IBC Approval Before Initiation	"Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL." It is unclear if work with agents like pangolin coronavirus (not new, used at BSL-3 for years) needs to stop and wait for clearance.	
Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	Requires Full Committee Review (FCR): "Research involving genetically modified cells" The purchase and use of pre-made genetically modified cells is low risk or the risk is limited to the potential presence of bloodborne pathogens.This would be more reasonable at the Delegated Member Review level.	As with the previous NIH Guidelines, base the review path on a risk assessment of potential creation methods (e.g., viral vectors) or on the planned use (e.g., engrafted into animals).
Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	Requires Full Committee Review (FCR): "Research involving toxins listed as select agents" 1) As mentioned above, toxins align more closely with chemical hazards than biohazards. There are Safety Data Sheets available, so full committee review is overkill. 2) For those institutions that are registered for select agents, this process may be redundant to the required Due Diligence program.	1) Remove toxins from scope of policy or 2) Allow Delegated Member Review.
Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	Requires Full Committee Review (FCR): "Research with primary cells that may be contaminated by adventicious agents." Precautions are outlined by the OSHA Bloodborne Pathogens Standard. Requiring FCR for this is disproportionate for the level of risk and expertise needed. It is worth noting that work with a known culture of Hepatitis B virus is permitted to be DMR while a cell that might contain HBV is FCR.	Allow Delegated Member Review.
Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	Requires Full Committee Review (FCR): "Research with primary cells that may be contaminated by adventicious agents." It is unclear if this includes any human study that involves a blood draw (as blood could meet the definition of a primary cell that may be contaminated by BBP). This could add approximately 50-80 protocols to FCR every month. It would lead to significant, unnecessary delays in time to activation.	Please clarify if a blood draw is included in this definition.
Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	Requires Full Committee Review (FCR): Clinical research involving Risk Group 2 or higher biological agents. 1) While the level of risk is admittedly higher here, it is worth noting that this work is already going through the IRB for patient safety. 2) This will add to time to activation, which has been a concern for the IRB.	N/A

Section / item	Comment	Suggested change
Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	Requires Delegated Member Review (FCR): "Research with transgenic organisms at BSL-1/ABSL-1." There is no exemption for transgenic rodents. 1) The only risk for use of a transgenic animal would be the biosecurity concerns around escape, which are under the purview of the IACUC. This is a redundant effort. 2) We estimate approximately 250 studies that involve transgenic rodents. This is significantly increased administrative burden when the risk is negligible.	As with the previous NIH Guidelines, make an exemption for the use, breeding, and purchase of transgenic rodents where risk is negligible.
Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	Requires Delegated Member Review (FCR): "Research with plasmids" There is no longer an exemption for everyday cloning in nonpathogenic *E. coli.* Note that UMB has expected IBC submission for cloning, but as an exempt procedure, it was not NIH reportable when we found that a PI had not submitted.	As with the previous NIH Guidelines, make the use of plasmids in non-pathogenic *E. coli* exempt.
Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	Requires Delegated Member Review (FCR): "minor amendments to previously approved submissions." What is considered a minor amendment is not defined. Does it include a new gene expressed by a previously approved vector (where the risk assessment in place is sufficient)? Or is it meant to be administrative details like personnel amendments only?	Define "minor amendments."
Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	Requires Delegated Member Review (FCR): "Research with well-characterized cell lines." What is considered well characterized? Is it pathogen tested? It is possible to not be a primary cell (listed for FCR) or a well characterized cell line (listed for DMR), so these materials would presumably default to FCR.	Define "well characterized."
Other Comments	There seems to be a fundamental misunderstanding of where administrative burden comes from related to IBC protocols. Some experiments have moved from FCR to DMR, which will help with time to activation and committee members' time. However, they have eliminated exemptions for low risk materials (now all DMR) and expanded the scope, so there is a massive increase in what will need to be submitted to the IBC. The writing of a protocol and its preliminary review are the most time consuming aspects for PIs and the biosafety team respectively.	As with the previous NIH Guidelines, bring back exemptions for predefined categories that are extremely common and low risk.

Section / item	Comment	Suggested change
Other Comments	The comparison table released by the NIH OSP has a row on clinical protocols that only lists the "Products that are capable of shedding, replicating, or integrating; Products that require higher risk manipulations (e.g., aerosolization, bladder infusions); and RG2 or higher wild type biological agents (e.g., challenge experiments for medical countermeasures)" as needing FCR. It is unclear if use of a select toxin (e.g., botox) in a clinical setting requires FCR as select toxins are explicitly listed above that on the draft policy list. (Note: This is connected to the blood draw concern mentioned above for which it is unclear what their expectations for clinical protocols are due to the poor organization of the list.)	Make clear what clinical protocols require FCR, only the three bullet points under the clinical sentence or anything in the FCR category.
Other Comments	Because the draft policy greatly expands the scope of what is covered, more incidents will need to be reported. This includes reports of unapproved research for experiments that were previously exempted due to low risk.	Make incident reporting risk based.
Part 3. Incident Narrative	By including PI name, a person's position, and potentially using a specifc pronoun, it would become possible to figure out the identity of an injured person or a person involved in an accident (e.g., spill). This could be referenced by anyone on the internet, including prospective employers. We anticipate some accidents to go unreported due to fear of details being posted on the website.	Not require personnel details if posted on a website. Could post a general incident report summary annually.
Overall format, length & usability	When timed, we found it takes an analyst about 30-40 minutes longer per protocol to write minutes in this level of detail. Considering the increase in total scope of the policy, creating minutes is near a complete FTE. Many additional details, such as specifics of the material used, will likely be	As with the previous NIH Guidelines, list what information must be included and allow institutions to meet the requirements as they determine appropriate.
New IBC Registrations and Amendments for Review	The section entitled "Readout of any projects approved by delegated member review" is in the middle of details needed for each protocol. This is confusing and it is difficult to determine if DMR protocols can be just listed or need more details.	Clarify differences between minutes requirements for DMR versus FCR.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Define the policy's organizing terms-- Add a clear definition of "biohazard" and use it consistently throughout the policy. Define "biological agent" neutrally, then distinguish biological agents that meet risk-based criteria for oversight. Align the definitions of biomedical research, laboratory research, genetic modification, genetically modified organism, transgenic organism, toxin, prion, self-aggregating protein, well-characterized cell line, and clinical research involving biohazards.

Establish an exposure-based scope test-- State that a material or activity is covered when there is a credible pathway of exposure or release and a plausible risk to human health, public health, animal or plant health, or the environment, as applicable. Distinguish plausible risk from remote theoretical risk.

Publish an applicability matrix-- Identify activities requiring no review, administrative review, delegated review, full IBC review, and NIH plus IBC review. Include examples involving blood and other potentially infectious materials, environmental samples, validated inactivated materials, routine cell lines, transgenic rodents, plant-associated microorganisms, diagnostic work, core facilities, clinical sites, affiliates, leased space, and off-site collaborations.

Clarify plant, animal, agricultural, and environmental coverage-- State expressly whether animal-only pathogens, plant pathogens, genetically modified plants, and environmental-release research are within scope. Explain when another federal agency's oversight replaces, partially satisfies, or operates concurrently with NIH-policy and IBC requirements.

Narrow the definition of genetic modification-- Limit mandatory oversight based solely on genetic modification to intentional engineering or other changes that may affect biological risk. Distinguish deliberate engineering from conventional selection, adaptation, passaging, reassortment, chemical mutagenesis, radiological mutagenesis, and incidental or collateral changes. Base the review pathway on the resulting phenotype, intended function, and risk.

Calibrate toxin oversight to meaningful risk-- Define oversight using factors such as potency, quantity, concentration, biological activity, formulation, and route of exposure. Establish De Minimis thresholds or exemptions where appropriate. Clarify the status of inactive derivatives, isolated subunits, peptides, low-risk toxin preparations, and nucleic acids encoding toxins.

Limit the self-aggregating protein category-- Clarify that heightened oversight applies to transmissible, experimentally propagating, or disease-associated self-aggregating proteins, rather than ordinary protein aggregation without comparable biological risk.

Create a distinct clinical-research framework-- Define clinical research involving biohazards separately from laboratory research and provide clinical-specific review and
mitigation criteria. Clarify manufactured cell products, direct vector administration, shedding, replication or integration, higher-risk administration procedures, multicenter responsibilities, expanded-access exclusions, and risk-based endpoints for IBC oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Establish a clear precedence rule-- State which review category controls when Sections IV-1, IV-2, and IV-3 overlap. Provide a decision table with examples for NIH review, full IBC review, delegated review, administrative registration, documentation only, and exclusion.

Reserve federal preapproval for defined high-risk or uncertain research-- Limit mandatory NIH preapproval to circumstances involving substantial uncertainty, genuinely novel hazards, or potentially significant public-health or environmental consequences. Permit IBCs to make local determinations for well-characterized agents when adequate information supports the assessment.

Make NIH determinations reusable-- Create a searchable national repository of NIH risk-classification and containment determinations. Define substantial equivalence, permissible deviations, required documentation, who decides whether precedent applies, and which changes require a new petition.

Create lower-burden pathways for minimal-risk work-- Allow documented institutional screening, exemption, or registration for established well-characterized cell lines, commercial transgenic animals maintained at ABSL-1, genetically modified RG1 organisms, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, and low-risk toxin work. Preserve institutional authority to elevate review based on local risk factors.

Define delegated-review procedures-- Specify reviewer eligibility, conflict-of-interest requirements, access to review materials, criteria for elevation, treatment of initial submissions and amendments, and the status of approvals. Define “minor amendment” as a change that does not materially alter the risk assessment, containment, or principal mitigation strategy.

Make reporting of delegated approvals proportionate-- Allow a concise approval report to the IBC, with complete records retained for oversight and review. Clarify whether post-approval reporting is informational and under what circumstances a delegated decision may be reconsidered.

Adopt risk-based renewal and post-approval review-- Replace a uniform renewal interval with an approach that permits more frequent review of higher-risk or changing research and longer intervals for stable lower-risk activities. Distinguish de novo renewal, continuing review, minor amendments, and administrative changes.

3. Continued utility of Risk Groups: Retain RGs as a starting point, not a final determination-- Use Risk Groups for initial hazard characterization and communication, while requiring experiment-specific and site-specific assessment before assigning containment or oversight. State expressly that RG and BSL or ABSL classifications are related but not interchangeable.

Require phenotype- and procedure-based assessment of modified agents-- Begin with the parent agent, then evaluate how modifications affect pathogenicity, virulence, transmissibility, host or tissue range, replication competence, environmental persistence, toxicity, allergenicity, countermeasures, and exposure routes. Include procedure, scale, aerosol generation, sharps, animal work, personnel expertise, facility capability, and available mitigations.

Clarify the hierarchy of policy and guidance-- Explain how binding policy requirements, BMBL recommendations, RG classifications, NIH determinations, and institutional risk assessments interact and how conflicts are resolved.

Expand worked examples and national reference resources-- Provide examples for attenuation, replication-defective constructs, opportunistic agents, unclassified agents, validated inactivation, toxins, prions, gene-drive systems and components, synthetic or AI-designed sequences, multi-source constructs, and influenza reassortants, pseudotypes, strains, and segments. Maintain a current, publicly accessible RG and containment resource.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Separate core safety principles from award-administration requirements-- Identify which provisions represent broadly applicable biosafety practices and which are specific to NIH assurances, public posting, recordkeeping, federal notification, or grant administration.

Provide shared resources and participation incentives-- Offer model policies, training, risk-assessment tools, access to national containment determinations, and participation in confidential de-identified incident-learning systems. Permit shared, consortium, external-IBC, and mutual-aid models for organizations with limited internal capacity.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reporting Create a risk-based reporting decision table-- Define incident, confirmed exposure, potential exposure, laboratory-acquired infection, loss of containment, release, minor spill, near miss, basic first aid, agent-specific treatment, compliance violation, and equipment or facility failure. Distinguish immediate NIH notification, later full reporting, local IBC review, institutional management, and voluntary confidential reporting.

Focus federal reporting on biosafety-significant events-- Require federal reporting for credible exposures or releases, potential laboratory-acquired infections, materially compromised containment, significant unauthorized work, and other events with meaningful public-health or community implications. Exclude

routine occupational injuries unrelated to biohazard exposure or release.

Clarify ambiguous reporting scenarios-- Address precautionary medical evaluation, post-exposure prophylaxis, adventitious agents, mixed or uncertain exposures, first-aid-only events, animal incidents, properly contained and disinfected spills, administrative deficiencies, and equipment failures when redundant containment remains functional.

Define reporting clocks and incomplete-investigation procedures-- Specify whose awareness starts the 24-hour notification period, the minimum initial information, when the 30-day period begins, and when an interim report is acceptable because an investigation remains incomplete.

Replace detailed public incident reports with de-identified summaries-- Separate confidential information submitted to NIH from information intended for public disclosure. Public summaries should address the general nature of the event, risk, contributing factors, corrective actions, lessons learned, and oversight outcome without names, medical information, grant identifiers, proprietary details, or security-sensitive information.

Preserve confidential near-miss reporting-- Maintain a nonpunitive, de-identified learning pathway with clear limits on disclosure and enforcement use so that public-posting requirements do not discourage reporting.

Meeting minutes
Treat templates as content standards rather than fixed layouts-- Permit institutions to use established minutes formats when all required elements are present. Allow a public IBC roster to satisfy recurring documentation of member expertise when it contains sufficient information.

Define public-detail and redaction standards-- Specify the level of project detail required in public minutes and permit redaction of personal, medical, proprietary, grant-related, and security-sensitive information. Permit concise summaries of incidents, inspections, and delegated approvals.

Provide a reasonable posting period-- Replace “immediately after approval” with a defined period that accommodates preparation, redaction, quality review, holidays, and staffing constraints. Clarify whether public access to meetings is required or encouraged.

6. Other feedback relevant to this resource: Release complete implementation materials before the effective date-- Provide a standardized Biosafety Assurance template, applicability and review-pathway decision tools, model policies and charters, responsibility and reliance agreements, risk-assessment forms, worked examples, training materials, completed sample templates, redaction guidance, and guidance for shared or external IBCs.

Define the Biosafety Assurance process-- Specify required, conditional, and optional information; authorized signatories; submission and renewal procedures; completeness criteria; NIH review and response processes; approval scope and duration; material updates; reliance arrangements; and public versus confidential information. Preserve continuity during timely review of a complete renewal or transition submission.

Align authority with assigned responsibilities-- Define institutional leadership accountability and provide IBCs, BSOs, and biosafety-program leadership with authority, independence, access, escalation pathways, corrective-action mechanisms, and stop-work or suspension authority appropriate to their assigned functions.

Allocate responsibilities according to operational control-- Assign building systems, ventilation, emergency power, capital repairs, certification programs, and centralized maintenance to the responsible institutional functions rather than placing sole responsibility on investigators. Require biosafety training for PIs as well as supervised research personnel.

Clarify governance and conflicts of interest-- Define IBC establishment, charter authority, appointments, quorum, voting thresholds, recusals, remote participation, consultants, unaffiliated membership, suspension authority, and protection of independent biosafety judgment. Do not count a recused member toward the quorum required to act on the affected matter.

Address compliance costs and flexible institutional models-- Recognize appropriate biosafety costs, support workforce development and shared training, and permit shared personnel, contractors, consortium IBCs, external IBC services, and mutual-aid arrangements when authority, expertise, availability, reporting relationships, and accountability are documented.

Publish crosswalks and coordination guidance-- Explain the relationship of the final policy to the NIH Guidelines, federal high-risk research and DGOF or potential-DGOF oversight, Select Agent requirements, and other federal authorities. Identify review ownership, information-sharing expectations, and when oversight is cumulative or substitutive.

167. Tammy Bavaret, MS, PhD, RBP, CBSP, SM(NRCM)

I am responding: On behalf of myself

Name: Tammy Bavaret, MS, PhD, RBP, CBSP, SM(NRCM)

Name of Organization:

Type of Organization: Not Applicable

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/14/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Basic research, translational research, clinical research, recombinant and synthetic nucleic acid research, gene-editing technologies, and Biosafety Level 3 (BSL-3) operations

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's efforts to establish a comprehensive biosafety framework that extends beyond recombinant and synthetic nucleic acid research to include a broader range of biological hazards. Expanding the scope of oversight recognizes the evolving nature of biomedical research and provides an opportunity to apply a more consistent, risk-based approach across research activities.
However, I believe additional clarification is needed regarding the scope of covered research and the definition of "biohazard." The policy would benefit from more explicit guidance regarding activities involving genetically modified organisms, gene-editing technologies, attenuated agents, validated inactivated materials, self-amplifying RNA platforms, AI-assisted biological design, toxins, prions, and other emerging technologies. Clear examples should be provided to assist institutions in making consistent determinations regarding whether specific activities fall within the policy's scope.
I am also concerned that certain clinical research activities may inadvertently fall outside of biosafety oversight under the proposed framework. The draft policy appears to narrow clinical review triggers by focusing primarily on characteristics such as replication, integration, and shedding. While these are important considerations, they may not fully capture the potential biosafety implications of emerging gene-editing technologies or other biologically active investigational products. I encourage NIH to further evaluate whether additional oversight triggers are warranted to address these activities.
Finally, NIH should provide additional guidance regarding collaborative research, affiliates, leased facilities, community-based research sites, and multi-site clinical studies to ensure that oversight responsibilities are clearly assigned and consistently implemented.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support a tiered oversight model that aligns the level of review with the degree of biological risk. A risk-based framework allows institutions and oversight bodies to focus resources on activities that present the greatest potential impact to laboratory personnel, research participants, public health, agriculture, or the environment.
In general, local Institutional Biosafety Committees are well positioned to evaluate institution-specific factors such as personnel expertise, facility capabilities, local standard operating procedures,

occupational health resources, and training programs. These factors are often critical to an accurate risk assessment and are best evaluated at the local level.
Federal oversight should be reserved for activities involving novel or particularly consequential biological risks, including situations where standardized national review promotes consistency and public confidence. NIH review may be particularly appropriate for activities involving significant uncertainty, broad societal implications, or technologies that do not fit within established oversight frameworks.
To support consistent implementation, NIH should provide clear criteria and decision tools that help institutions determine when local review is sufficient and when federal review is warranted. Absent such guidance, there is potential for significant variability among institutions conducting substantially similar research.

3. Continued utility of Risk Groups: I strongly support continued use of Risk Groups as the starting point for biosafety risk assessment.
Risk Groups and Biosafety Levels serve distinct but complementary functions. Risk Groups characterize the inherent hazards associated with an organism, while Biosafety Levels represent containment practices and facility requirements selected following a comprehensive risk assessment. Maintaining this distinction remains important because containment decisions should be informed by the biological characteristics of the agent, nature of the modifications, routes of exposure, and specific experimental procedures.
At the same time, Risk Groups alone are not sufficient when evaluating genetically modified organisms. Modifications may increase, decrease, or otherwise alter risk in ways not reflected by the parent organism's Risk Group classification. Therefore, Risk Groups should continue to serve as the foundation of risk assessment while allowing institutions to incorporate additional factors related to genetic modifications, host range, pathogenicity, environmental persistence, transmissibility, and potential consequences of exposure.
Rather than replacing Risk Groups with Biosafety Levels, I recommend that NIH maintain the current approach in which Risk Groups inform the assessment process and Biosafety Levels are selected based on the outcome of that assessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The success of the policy will depend in part on its ability to encourage broad adoption beyond institutions that are formally required to comply.
NIH can promote voluntary compliance by providing practical implementation resources that reduce barriers to participation. Examples include model policies, biosafety assurance templates, institutional self-assessment tools, risk assessment templates, sample standard operating procedures, training materials, and decision trees.
NIH should also recognize and support reliance models that allow smaller institutions, community hospitals, physician practices, and independent research organizations to access qualified biosafety expertise through external IBCs and shared oversight arrangements. Many organizations lack the resources to maintain a fully independent biosafety program but remain committed to implementing high-quality biosafety practices.
Additional incentives could include educational outreach, publicly available training resources, recognition programs, and technical assistance opportunities that help organizations align with NIH expectations even when compliance is voluntary.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I support NIH's effort to standardize incident reporting and meeting documentation. Consistent reporting structures can improve trend analysis, facilitate lessons learned, and promote greater transparency across the research community.

For the Incident Reporting Template, I recommend NIH:

• Clearly distinguish reportable incidents from events that may be managed locally.
• Define key reporting terms such as exposure, containment breach, laboratory-acquired infection, near miss, and significant incident.
• Include fields that capture root-cause analysis, corrective actions, and preventive measures.
• Provide guidance regarding protection of confidential, proprietary, personnel, medical, and security-sensitive information.
• Clarify whether all submitted information will be made publicly available and, if so, what information may be redacted.

For the Meeting Minutes Template, I recommend NIH:

• Allow flexibility for documenting discussions in a manner appropriate to committee complexity.
• Clarify expectations for documenting dissenting opinions and conflict-of-interest recusals.
• Clearly distinguish required elements from optional meeting notes.
• Provide guidance regarding management of confidential information and proprietary research details included in meeting records.

The templates should facilitate meaningful documentation while minimizing unnecessary administrative burden.

6. Other feedback relevant to this resource: The implementation resources provided are a valuable starting point, but additional guidance will likely be necessary to support successful adoption across the research community.

The areas where further guidance would be most beneficial include:

• Clinical research oversight and applicability.
• Gene-editing technologies and genome engineering platforms.
• Emerging biotechnology applications that may not fit existing categories.
• Delegated review mechanisms and risk-based oversight pathways.
• Externally administered IBC models and reliance agreements.
• Institutional responsibilities under Biosafety Assurances.
• Multi-site and collaborative research oversight.
• Incident reporting expectations and public disclosure requirements.
• Risk assessment methodologies for modified organisms and novel constructs.
• Transition planning for currently compliant institutions.

I also recommend that NIH develop a comprehensive implementation toolkit that includes examples, frequently asked questions, decision trees, sample policies, risk assessment templates, and illustrative case studies. These resources would significantly improve consistency and reduce implementation challenges across institutions of varying size and complexity.

Additional comments/suggestions are provided in the attachment as well.

Description: Additional Comments on the Draft NIH Biosafety Policy

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Thank you for the opportunity to provide comments on the Draft NIH Biosafety Policy for Research Involving Biohazards.

As a Certified Biological Safety Professional (CBSP), Institutional Biosafety Committee (IBC) Chair, Biosafety Consultant, and former Assistant Director of Biosafety and Biocontainment Operations/Institutional Biosafety Officer, I have more than a decade of experience supporting biosafety and biosecurity programs, managing IBC operations, conducting biological risk assessments, overseeing high-containment laboratory programs, and advising research institutions on compliance with federal biosafety requirements. My experience includes oversight of basic research, translational research, clinical research, recombinant and synthetic nucleic acid research, gene-editing technologies, and Biosafety Level 3 (BSL-3) operations. I currently serve as Chair of Institutional Biosafety Services for externally administered IBCs, where I lead reviews of clinical and non-clinical research protocols and support institutions navigating complex biosafety oversight requirements.

I support NIH's efforts to modernize biosafety oversight and establish a comprehensive framework that protects research personnel, research participants, the public, and the environment while enabling responsible scientific advancement.

Overall, I encourage NIH to further refine the policy to improve consistency, clarify applicability, strengthen institutional accountability, and ensure oversight requirements remain proportionate to actual biological risk. Particular attention should be given to clinical research, implementation logistics, externally administered IBC models, and the operational challenges institutions will face when transitioning to the new framework.

1. Scope and Applicability

The policy would benefit from greater clarity regarding which activities, sites, institutions, and research types fall within its scope.

I recommend that NIH provide:

- A clear applicability matrix identifying activities requiring no review, administrative review, delegated review, full IBC review, or NIH review.
- More precise definitions of covered research, institutional sponsorship, affiliates, leased facilities, collaborative research, and off-site activities.

- Additional examples addressing common research activities such as work with established cell lines, transgenic animals, validated inactivated materials, plant pathogens, agricultural research, and veterinary research.
- Clear guidance regarding how NIH oversight intersects with requirements from other federal agencies.

Institutions need practical decision-making tools that can be applied consistently across diverse research environments.

2. Clinical Research Oversight

One area that warrants substantial clarification is the treatment of clinical research.

Under the current NIH Guidelines, IBC oversight applies broadly to many clinical studies involving recombinant or synthetic nucleic acid technologies. The draft policy appears to narrow oversight considerably by limiting review triggers primarily to specific characteristics such as replication, shedding, or integration. As written, this creates uncertainty regarding whether certain clinical products would remain subject to biosafety review despite presenting meaningful biological risk.

I encourage NIH to develop a dedicated clinical research section similar in scope and detail to the current NIH Guidelines rather than addressing clinical oversight through a limited subsection embedded within broader laboratory research categories.

Particular clarification is needed regarding:

- Whether the clinical research provisions are intended to be the sole basis for determining IBC review requirements for clinical studies.
- The relationship between clinical review categories and delegated review pathways.
- Oversight expectations for multicenter studies.
- Oversight endpoints when biological activity may continue after final administration of a product.
- Circumstances under which institutions may apply additional biosafety review based on local risk assessments.

The biosafety implications of clinical research frequently extend beyond the clinical setting and may involve exposure risks to healthcare workers, laboratory personnel, caregivers,

family members, and communities. The policy should ensure these considerations are addressed consistently.

3. Gene Editing and Emerging Technologies

The draft policy appears to focus heavily on integrating vectors while providing limited discussion of modern genome-editing approaches.

I recommend adding gene editing as an independent consideration for oversight rather than relying solely on integration-based triggers.

Technologies such as:

- CRISPR systems,
- Base editors,
- Prime editors,
- Non-homologous end joining approaches,
- Self-amplifying RNA systems, and
- Future genome-engineering platforms

may create significant and lasting biological effects even when they do not involve traditional integration events.

Oversight decisions should be informed by biological function, potential exposure consequences, and residual risk rather than by platform classification alone. The final policy should also be flexible enough to accommodate emerging technologies that may not fit neatly within current regulatory categories.

4. Risk Assessment Framework

I support continued use of Risk Groups (RGs) as the starting point for biosafety risk assessment.

Risk Groups describe the hazard characteristics of an organism, whereas Biosafety Levels (BSLs) represent containment measures selected after completion of a risk assessment. Maintaining this distinction is important because containment decisions should flow from the characteristics of the agent and proposed work rather than serve as the starting point for evaluation.

Additional guidance would be valuable for:

- Genetically modified organisms.
- Attenuated strains.
- Validated inactivated materials.
- AI-designed sequences.
- Gene-drive technologies.
- Toxins.
- Prions and self-aggregating proteins.
- Novel or proprietary constructs.

Standardized risk assessment templates and examples could help improve consistency across institutions and reduce variability in oversight determinations.

5. Institutional Accountability and Program Infrastructure

The success of the policy will depend heavily on institutional capacity.

NIH should explicitly identify the responsible institutional authority accountable for biosafety program implementation and ensure institutions maintain sufficient infrastructure to support compliance.

Minimum expectations should address:

- Professional biosafety expertise.
- Administrative support.
- Committee operations.
- Training programs.
- Records management.
- Occupational health support.
- Incident response capabilities.
- Compliance monitoring activities.

I also encourage NIH to recognize that institutions vary significantly in size and complexity and should permit documented reliance arrangements, shared resources, and qualified external support when responsibilities and authorities are clearly defined.

6. Institutional Biosafety Committee Operations

The policy would benefit from a clearer separation between committee governance requirements and substantive biosafety responsibilities.

Additional clarification should address:

- Quorum requirements.
- Management of conflicts of interest.
- Delegated review procedures.
- Required expertise.
- Voting standards.
- Authority to suspend or withdraw approvals.
- Emergency response authorities.
- Risk-based inspection frequencies.

In particular, members recused due to conflicts of interest should not be counted toward decision-making quorum for the affected protocol. NIH should also consider providing examples of acceptable delegated review practices to promote consistency among institutions.

7. Incident Reporting and Public Transparency

I support the goal of increasing transparency and improving biosafety learning across the research community. However, reporting requirements should be structured in a manner that encourages, rather than discourages, timely reporting.

The final policy should:

- Clearly distinguish incidents requiring NIH notification from events that can be managed locally.

- Define key terms such as exposure, containment loss, near miss, laboratory-acquired infection, and significant incident.
- Clarify reporting timelines and investigative expectations.
- Establish appropriate redaction standards to protect personal, medical, confidential, proprietary, and security-sensitive information.

Consideration should also be given to the possibility that mandatory public posting of incident reports could inadvertently discourage prompt reporting if individuals fear public identification, reputational consequences, or misinterpretation of events that ultimately pose little risk. Balancing transparency with appropriate privacy and security protections would better support a strong reporting culture.

8. Clarification of Key Operational Terms

Several terms serve as major triggers for oversight but are not currently defined with sufficient precision.

I recommend that NIH provide clear operational definitions and examples for:

- Shedding.
- Replicating products.
- Higher-risk manipulations.
- Containment failures.
- Integrating versus gene-editing technologies.
- Adventitious agent contamination.
- Environmental release.
- Biological exposure.

Without standardized definitions, similar research may receive substantially different oversight determinations at different institutions, creating inconsistency across the research enterprise.

9. Externally Administered IBCs

Many community hospitals, physician practices, rural research sites, independent research organizations, and smaller institutions rely on external IBCs because maintaining a fully independent biosafety program is not operationally feasible.

The final policy should clearly permit reliance arrangements that allow qualified external IBCs to:

- Support Biosafety Assurance requirements.
- Provide biosafety policies and procedures.
- Maintain required records.
- Host required public-facing postings.
- Coordinate reporting activities.
- Assist with compliance monitoring.
- Provide risk assessment expertise and regulatory support.

Institutions should remain accountable for compliance while retaining the flexibility to leverage qualified external expertise.

Such an approach would improve consistency, reduce administrative burden, increase access to qualified biosafety professionals, and facilitate implementation across diverse institutional settings.

10. Implementation Timeline

The proposed implementation timeline may underestimate the scope of institutional changes required.

Institutions will need to:

- Identify newly covered activities.
- Establish or revise Biosafety Assurances.
- Update policies and procedures.
- Train researchers and staff.
- Expand committee capacity.
- Implement recordkeeping systems.

- Revise reporting workflows.
- Develop or update risk assessment processes.

I therefore recommend a phased implementation strategy with at least 12 months between publication of final guidance and full compliance requirements.

This transition period should include published templates, implementation resources, examples, decision tools, and frequently asked questions before institutions are expected to comply with new requirements.

Conclusion

I support NIH's objective of creating a modern, risk-based biosafety oversight framework. I encourage NIH to clarify the policy's scope, strengthen implementation guidance, ensure consistent oversight of clinical research and emerging technologies, provide practical accommodations for externally administered IBC models, and align oversight obligations with demonstrable biological risk.

From my experience leading institutional biosafety programs, managing IBC operations, conducting risk assessments, and supporting both academic and clinical research environments, I believe these enhancements would improve consistency, strengthen biosafety oversight, and promote successful implementation across the diverse institutions conducting biomedical research today. Ultimately, a clear, practical, and risk-based policy framework will better support both scientific advancement and public trust in the research enterprise.

Uploaded File: Recommendations-to-NIH-OSP-NOT-OD-26-112-October2026.docx

Recommendations to the National Institutes of Health Office of Science Policy

We support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. **Purpose and program identity**

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. **Scope definitions and implementation**

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide

coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Request for consideration. Current definitions of genetic modification generally center on techniques or experiments that cause heritable or persistent changes to the genetic material of a host cell or organism; that is, genomic DNA, or genomic RNA for certain viruses. However, the proposed definition includes nucleic acids that "can be transcribed or translated," which could classify many established vaccine technologies as genetic modification even when the platform does not alter the recipient's genome. NIH should consider revising the definition to distinguish genome-altering technologies from transient expression or translation of introduced nucleic acids. NIH should also clarify whether nonintegrating messenger RNA, self-amplifying RNA, nonintegrating DNA, and other transient vaccine platforms are intended to fall within scope; explain how persistence, integration potential, heritability, and biological function affect classification; and provide examples identifying when vaccine research requires IBC review, documentation only, or no review. Any expanded definition should be scientifically justified, risk-based, and coordinated with relevant FDA requirements to avoid duplicative or inconsistent oversight.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. **Institutional accountability and Biosafety Assurances**

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether

separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

1. **IBC establishment functions and operations**

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

2. **Investigator responsibilities and voluntary reporting**

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

3. **NIH implementation responsibilities and coordination**

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

4. **NIH review and containment determinations**

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

5. **IBC review pathways and clinical oversight**

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

6. **Risk assessment and specialized materials**

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious diseases; microbiology; virology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope requires further clarification, as biohazards go beyond just those posing risk/potential risk to human health. Given the exclusion of applicability to plants and animal-only pathogens, there would need to be policies separate that address those. Will those be coming from the USDA and/or APHIS? These policy silos are not mutually exclusive and it may be dangerous to treat them as such.

Is known or suspected/potential risk the necessary criteria for all research subject to this policy? If we are excluding animal-only pathogens, this would seem to confuse the requirement for IBC membership to include animal-containment SME, incident reporting for research animals, and, expressly-referenced zoonotic agents. Further clarity is needed to specify intent, animal-related procedures and environmental consequences are exempt unless zoonotic or genetically modified.

Clean and comprehensive definitions of what this policy refers to/covers as biological agents, BBPs, environmental samples, and prions. As an example, the stated definition of a “biological agent” excludes non-pathogenic organisms, animal-only pathogens. This is confusing, with respect to later policy references to “biological agent” when discussing RG1 materials, zoonotic agents, genetically modified agents,, environmental impacts, and organisms not currently known to cause disease in humans. As currently written, clarification is needed with regard to whether the aforementioned is exempt from the policy and what other policies now or in the future will address these.

Broader application of institutions receiving NIH funding. As currently worded, it seems as though the research that is not NIH-funded is still under the purview of this policy by proxy of an institution receiving NIH-funding elsewhere. This is an important distinction, in terms of bandwidth considerations for any direct and any indirect support stakeholders and considering what additional constraints this implicates.

Research involving plants - policy references environmental containment, ecological risk assessment, and

GDMOs intended for environmental release. This further necessitates capturing plants as part of this policy or having a separate policy to address this category of research.

Research in clinical settings - can the BSO and/or IBC establish appropriate review and survey requirements? This policy should allow autonomy and flexibility to accommodate differences in physical environment, workflows, and risk mitigation measures that often vary widely from the typical research lab environment. A separate definition of clinical research that falls under this policy would be useful in clarifying the review process. Under section IV-2, clinical research involving deliberate biohazard administration to "one" human research participant should be clarified with respect to this being a limit for the number of participants before obtaining approval.

Roles and responsibilities - for the BSO vis-a-vis "periodic inspection" should be clarified as to be prescribed in an institution's Biosafety manual/IBC Charter or as part of this policy.

Administrative burden associated with review cycle may be significant, as currently articulated. Encourage the NIH to consider administrative burden and clarify "periodic review" of research. This is too vague.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Federal policy is clearly necessary to provide the framework. That's why clarity in this policy is crucial. Localized governance by letting the Biosafety professionals and the IBC members should maintain appropriate risk assessments and provide the best local oversight of controlling biological risk. This seems to disenfranchise that core principle by a fair margin.

Initial requests for NIH to lower containment below BSL-2 for research involving GDMOs - will the NIH publish the outcomes of its review for higher-risk research involving emerging, novel, or zoonotic agents for which RG classification or minimum containment level is not currently established in the BMBL? If such determination is established and it is published, will institutions still be required to submit individual protocols for NIH review or would that circumvent that need?

Full IBC review required for research involving toxins listed as Select Agents. Clarify if the NIH will accept or override all exemptions and permissible toxin amounts, as defined under the Federal Select Agent Program, whether inactive toxin derivatives or isolated subunits are considered "toxins," and whether nucleic acids encoding toxins are considered toxins and/or both.

Section IV-3 - for delegated review, must this include voting members of the IBC or can it include non-voting members, as defined by the institution's IBC? Can the institution define the process for notification, when granted, by delegated review - for reporting to the IBC?

3. Continued utility of Risk Groups: Used as a basis and appropriate risk assessments conducted locally to determine requests for adjustment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): This is requiring further clarification as to what applies. If the idea is make this a best practice regardless, more teeth should be added to that effect - including incentives for compliance.

Compliance violations at any BSL/ABSL must have clarity on what should be reported.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Requiring minutes to document individual's SME is duplicative, if required to publish a roster with that information already. Can we clarify if the roster availability satisfies this?

Policy should clarify expected level of detail for project descriptions - while protecting nature of the proprietary, confidential, or otherwise sensitive information.

Summaries of incidents should not contain identifiable information that is made public. People and organizations may insinuate this information, without names, provided the level of detail being required. Incidents should only be shared with the National Biosafety Data and Safety Analysis Center. Public posting of incidents will discourage proper reporting.

Scope of incident reporting should focus on events relative to Biosafety and Biosecurity risks - such as exposure to a hazard; release or potential release, lab equipment failures that result in exposure or release, and significant near misses involving biohazards.

6. Other feedback relevant to this resource: Succinct workflow diagrams and charts outlining roles and responsibilities, making determinations about what research applies, and when to report incidents would be helpful. Tip sheets and short guidance tools for researchers and Biosafety professionals alike would be extremely valuable complements.

170. N/A

I am responding: On behalf of an organization

Name:

Name of Organization:

Type of Organization: Institutional Research Oversight Committees e.g. IRB

Role: Organizational Official

Date Submitted: 10/14/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Neurological diseases, virology, cancer, and immunological diseases: both basic research and clinical studies

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: a. Inclusion of native pathogens, biological toxins, and pathogenic prions is appropriate because these agents present hazards that merit committee oversight. Our institution previously constituted and currently maintains a separate Biohazard Committee for this purpose. The revised Guidelines should explicitly permit two IBCs per institution to permit specialization between recombinant nucleic acids and the native pathogens, etc. included in the new scope, and to accommodate the expanded workload. The acronym GDMO for "gene drive modified organism" must be expanded in the policy's definition of "gene drive." A clear statement on whether plant research is intentionally being removed from NIH oversight, whether another agency (e.g., USDA) is assuming responsibility, or whether a separate policy is forthcoming would avoid a gap in oversight on this topic.

b. Oversight of clinical research is appropriate, given the development of nucleic acid-based agents that could affect not only patients but also their sexual partners, health care personnel who administer them, and families of the patients who receive them. Arguably the most important contribution of our IBC to clinical research, however, has been our scrutiny of Informed Consents, which have frequently been incomplete in their description of risks. An IBC collects and further develops expertise in gene transfer that may exceed that of an IRB charged with addressing many other issues. In our experience, IBC consent reviews are appreciated by the IRB because they provide assurance that all relevant risks have been considered and addressed. The Guidelines policy should explicitly encourage review of Consent documents by the IBC.

c. The draft policy's definition of "Genetic Modification" expands the oversight scope substantially with the following phrase: "The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical, or radiological means."
This phrase can be construed to include both embryological and pluripotent stem cells that are differentiated by passaging in specific environments, as well as cells that are deliberately subjected to mutagenic chemicals and ionizing radiation. Cells mutated by chemical or radiation mutagenesis and

stem cells that have been differentiated are unlikely to pose serious risks comparable to those of recombinant agents or native pathogens. We recommend that the Guidelines state that the differentiation of stem cells by passaging and routine chemical or radiation mutagenesis are outside the scope of the policy. Alternatively, provide examples and a clear risk-based threshold for when such work comes within the IBC scope.

d. Because the draft definitions of “biohazard” and “genetic modification” are so broad, activities that have long been regarded as negligible in risk could be construed as within scope, substantially increasing IBC workload without a corresponding gain in safety. The policy should include an explicit list of low-risk activities that are excluded from oversight (i.e. antisense oligonucleotides), or state clearly that institutions may establish and document their own exclusion criteria.

e. The draft extends the policy to non-NIH-funded research conducted at any institution that receives NIH funding. The current Guidelines contain a similar institution-wide condition, but only for recombinant or synthetic nucleic acid research; the draft applies it to all biohazards, including wild-type pathogens. The new Guidelines should clarify how this provision applies to industry- or privately sponsored work (i.e., sponsors of gene therapy agents in multisite clinical trials), to collaborative work conducted at other sites, and should avoid duplicative or conflicting review.

f. The proposal eliminates the dedicated human gene transfer category and instead relies on product characteristics (products capable of shedding, replicating, or integrating; higher-risk administration or manipulation procedures; and administration of RG2 or higher wild-type agents). We support a characteristic-based approach, but the Guidelines should state explicitly whether nucleic acid-based clinical products that do not meet these descriptors (for example, non-replicating, non-integrating nucleic acid therapeutics) are within scope. The policy should also preserve the IBC review of clinical protocols and other related documents to take maximum advantage of the IBC’s expertise.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): a. The requirement for quadrennial (or more frequent) certification of compliance by an institutional official and its verification by a federal oversight agency is not well described. The policy, as written without details, would enable a crippling and disproportionate institutional penalty for non-compliance regardless of severity or risk, without clear criteria and without opportunity for institutional appeal or remediation. A mechanism for evaluation of compliance that explicitly does not depend on the judgement of a single federal official, and that provides opportunity for appeal and remediation before cessation of federal support should be described in detail.

b. In Section III-B. “The institution shall establish an IBC to meet the criteria outlined in this policy.” The draft Guidelines acknowledge the possibility of a commercial external IBC by the phrase “and/or has an externally administered IBC” (Section IIIA bullet 2). The enlarged scope of oversight, the dependence on BMBL standards for risk assessment, and the requirements for incident reporting make it inconceivable to us that an external commercial IBC could accurately perform these functions. The BMBL places great emphasis on physical and engineering safety facilities, signage, and other laboratory-specific practices. These facilities and practices cannot be evaluated remotely. The more hazardous nature of native pathogen research compared to most recombinant or synthetic nucleic acid research strengthens the rationale for prohibition of external IBCs under the revised Guidelines.

c. The draft eliminates the simultaneous-notification category (current Section III-E). We recommend retaining an administratively exempt category for the lowest-risk research (for example, BSL1 work with well-characterized, non-hazardous materials) so that IBC time can be focused on research that warrants it. Delegated review, although helpful, still requires an IBC action on every protocol, and without a lower tier the expanded scope will substantially increase workload.

d. The proposal asks for a continuously updated IBC roster, IBC minutes, incident reports, biosafety training records, and it requires public posting of minutes and incident reports. We support transparency, but public posting of members' personal information and incident details creates privacy, personal safety, and security risks for members, investigators, and institutions. The Guidelines should specify which information must be public versus that provided only to the NIH, provide standard redaction criteria, and consider offering an NIH-hosted platform in place of separate institutional postings.

3. Continued utility of Risk Groups: a. Risk groups are very useful for native pathogens. Risk groups could be defined for specific viral vectors and pathogenic proteins. These would supplement the BMBL criteria. It should be the applicant's burden of proof to convince the IBC that their specific modifications of pathogens reduce the risk group or, in other ways relax the safety protocols by which agents in their pre-modification risk groups are handled.

b. The BMBL criteria for Biosafety Levels are highly dependent upon physical facilities, signage, documentation of procedures, practices, and laboratory visitors. As noted above, the Biosafety Level procedures could be followed and documented properly only with a local IBC.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): a. Our organization is funded by the NIH; hence compliance is required. We recommend free access to NIH-provided resources, including model SOPs, risk-assessment forms, training modules, and the incident-report and meeting-minutes templates, together with technical assistance from NIH OSP, to assist IBCs at all institutions in performing their duties regardless of NIH funding.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: a. The 24-hour (or "as soon as the institution becomes aware") NIH notification, followed by a complete report within 30 days, seems reasonable for confirmed laboratory-acquired infections and serious events. However, "potential LAI," "release with community risk," and "compliance violation" need operational definitions. As written, any compliance violation, however minor, could trigger a 24-hour report. We recommend that only significant violations (those involving actual or potential exposure or release) require 24-hour notification, and that minor violations corrected locally be documented by the IBC and available to NIH on request. NIH should also provide a reporting mechanism that is available outside business hours. Allowance must be made for delays until the IBC is informed.

b. Public posting of incident reports should be limited to what is necessary. Personal and medical information of employees and details that would reveal facility vulnerabilities must be redacted, and the template should separate public-facing fields from NIH-only content. Posting should occur only after investigation and any personnel actions are complete. For this reason, the 30-day timeframe appears to

be short. We believe that public posting of incidents for 5 years is counterproductive, since it would obscure the ability of institutions to correct problems over a much shorter period.

6. Other feedback relevant to this resource: a. Our institution will need time to revise and re-engineer the digital portal by which applications are created by the investigator and received and reviewed by the IBC and other committees that might have regulatory jurisdiction (IACUC and IRB). We request a one-year (or longer, rather than six-month), implementation grace period between adoption of the revised Guidelines and enforcement of compliance.

b. NIH should publish, before the compliance date, a list of frequently asked questions, a model institutional triage procedure, and model risk-assessment forms for investigators and IBCs.

c. Because no covered research may proceed until NIH approves the institution's Biosafety Assurance, NIH should publish review timelines and allow research to continue under the current framework during the transition and while the Biosafety Assurance renewal is pending.

d. Implementation will require additional IBC staff time and expertise. NIH should clarify that these are allowable administrative costs and facilitate access to such expertise, for example through a directory of qualified consultants who can serve as ad hoc advisors to local IBCs, while leaving local IBCs responsible for oversight of facilities and practices.

e. NIH should provide guidance on coordinating IBC review with IRB and IACUC review and with other federal programs to facilitate institutional compliance. This will also result in a smooth and streamlined workflow.

DARTMOUTH
Office of the Provost

Dean R. Madden, PhD
Vice Provost for Research
Professor of Biochemistry & Cell Biology
dean.madden@dartmouth.edu

October 14, 2026

To Whom It May Concern:

Thank you for providing the opportunity to comment on the National Institutes of Health (NIH) proposed biosafety policy for research involving biohazards. While we appreciate NIH's goal to modernize existing oversight of biohazards research and ensure the safety of the public, we urge NIH to revise or proceed cautiously with several provisions.

In particular, NIH requested input on the continued use of risk groups as a baseline for risk assessment. Dartmouth would encourage NIH to continue using existing risk groups as they remain well understood and very useful as a starting point in succinctly categorizing biological agents. Not using existing risk groups would greatly increase inconsistency and confusion between research institutions.

NIH must continue to provide clarity on the reference points for risk groups. The Biosafety in Microbiological and Biomedical Laboratories (BMBL) defers to existing NIH Guidelines, which are thus the primary source for risk group information. Consistent with the comments above, we also believe that any new policy should remain aligned with the current Guidelines. If any modifications are made, they should be designed to enhance alignment with international risk-group classifications. Whatever system is ultimately applied, NIH should also consider providing the updated list of approved risk groups or sources on its website.

Aside from these general suggestions, we also ask NIH to consider changes to specific sections as outlined below:

<u>Section II. General Definitions</u>

- Dartmouth recommends removing "passaging" from the second prong of the definition of genetic modification. Spontaneous mutation occurs in all maintained cultures whether or not the changes are deliberately selected.
- NIH should not include "clinical settings" in the definition of "laboratory research." First, its inclusion in the definition is confusing, given that later sections separate such research from other settings. Second, this would include clinical laboratories, for which additional oversight would not provide a meaningful improvement over the current process. These laboratories are typically overseen by strict accreditation standards, and further IBC oversight would add confusion without added benefit.

<u>Section III-B: Institutional Biosafety Committees (IBC) Responsibilities</u>

NIH should reconsider requiring institutions to post all incident reports on a public webpage, as not all incidents result in a public impact. Minor incident reports are key in understanding and

acting on institutional safety trends as a means of avoiding more significant incidents. Unfortunately, requiring all incident reports to be publicly posted will discourage reporting of minor incidents by researchers and may therefore have a paradoxical effect of decreasing safety. Only NIH-reportable incidents should be publicly posted, because those are the incidents with potential impacts on health.

Section IV-2: Research Requiring IBC Approval

- Research involving genetically modified cells should not be included in this section if the cells are not biological agents. Otherwise, a full IBC review would be required for lower risk cell lines such as common noninfectious cells, while only delegated review would be required for some higher-risk agents.
- NIH should further clarify that the statement that "primary cells that may be contaminated by adventitious agents" means primary cells that are known or reasonably suspected to contain other materials described in Section IV-2. All primary cells "may" contain adventitious agents and would therefore require full IBC review, while most adventitious agents themselves are RG2 and would only require delegated review.
- NIH should also provide greater clarity for the phrase "capable of shedding." Most products exhibit some form of shedding. It would be helpful to delineate more specific criteria, such as specifying if this means only intact and viable product, if it must be based on data for each individual product, and if preclinical data can be used. Most relevant clinical trials include shedding assessment, therefore agent-specific shedding data from humans are often not yet available, and most assessments are made by PCR, which does not indicate viability.

Section IV-3: Research Requiring Individual or Subgroup IBC Approval

NIH should better define what constitutes a "well characterized" cell line, or, alternatively, what would constitute a cell line that is insufficiently characterized for review under this section. Otherwise, institutions will have difficulty in assessing which cell lines require a deeper review process.

Thank you again for the opportunity to comment.

Sincerely,

Dean R. Madden, PhD
Vice Provost for Research
Professor of Biochemistry & Cell Biology

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biotech research CRO

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's effort to broaden biosafety oversight beyond recombinant nucleic acid research. One area that may need additional consideration is the management of biologically active recombinant products.

In my experience, risk assessments are often focused on the source organism, host system, vector, and genetic modification. However, some products generated from low-risk systems can themselves present significant occupational health hazards. Examples may include high-potency monoclonal antibodies, immune-modulating proteins, cytokines, growth factors, oncogenic proteins, and other biologically active molecules.

For these products, the hazard is not necessarily related to the Risk Group classification of the host organism. The concern may instead be related to the biological activity, potency, mechanism of action, and potential health effects of the expressed product.

I believe NIH should consider whether biologically active recombinant products that have the potential to cause adverse health effects should be specifically recognized within biosafety risk assessment requirements. This would help address a potential gap in oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A risk-based approach is appropriate. For biologically active recombinant products, local institutional review may be the most practical approach because the hazards are often product-specific and require detailed knowledge of the research activity.

NIH may consider providing guidance on when review by the Institutional Biosafety Committee (IBC) and Biosafety Officer (BSO) is expected, even when the work involves Risk Group 1 organisms.

3. Continued utility of Risk Groups: Risk Groups remain useful and should continue to be part of the assessment process. However, Risk Group classification alone may not fully capture the potential hazards associated with biotechnology-derived products.

A product expressed in a low-risk host may still pose a significant occupational health concern because of its biological activity. Therefore, risk assessments should consider both the characteristics of the organism and the hazard potential of the expressed product.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The policy would benefit from practical guidance documents, case studies, and examples that demonstrate how institutions can evaluate biotechnology-derived products with significant biological activity.

Many organizations outside NIH-funded research may be willing to adopt the framework if clear implementation guidance is available.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting template could include consideration of whether an incident involved exposure to a biologically active recombinant product and whether occupational health follow-up was required.

Capturing this information may help institutions better understand and learn from these types of events.

6. Other feedback relevant to this resource: Additional guidance would be helpful in the following areas:

Assessment of biologically active recombinant products.
High-potency monoclonal antibodies and related molecules.
Cytokines, growth factors, immune modulators, and oncogenic proteins.
Determining when IBC or BSO review is needed.
Examples of exposure assessment and control measures for biotechnology-derived products.

NIH may consider clarifying that biologically active recombinant products with significant occupational health implications should undergo review by Biosafety Officers (BSOs) and, where appropriate, Institutional Biosafety Committees (IBCs), as these groups possess the specialized expertise necessary to evaluate biological hazards that may not be readily identified through conventional Health and safety or industrial hygiene assessments alone.

Description: WSU IBC NIH Biohazard Policy Comments

DATE: October 15th, 2026

TO: NIH OSP

FROM: Wayne State University, Institutional Biosafety Committee
Detroit, MI

RE: WSU IBC Comments on the Draft NIH Policy for Biohazard Research

Purpose

This memo provides a consolidated list of comments that the WSU Institutional Biosafety Committee (IBC) have provided for submission in response to the request for feedback on the NIH draft policy on biohazard research. The comments support modernization of biosafety oversight while requesting clearer scope, objective review criteria, workable transparency protections, coordinated governance, and a realistic implementation framework.

Section 1. Scope, Definitions, and Applicability

Comment

The draft policy includes several terms that lack sufficiently objective applicability criteria, including *"biomedical research," "potential risk to human health," "well-characterized cell lines," "primary cells," "toxins,"* and *"genetic modification."* As written, these terms may be interpreted differently across institutions, resulting in inconsistent implementation and uncertainty regarding which activities require IBC oversight.

NIH should provide clear definitions, exclusions, examples, and decision-making tools that enable institutions to determine consistently whether an activity falls within the scope of the policy. Additional clarification is needed for common research activities and materials, including cell culture systems, toxins, genetically modified organisms, validated inactivated materials, and other activities for which applicability may not be readily apparent.

Rationale

A central objective of the proposed policy is to ensure appropriate oversight of research activities that may pose a meaningful risk to human health, animal health, agriculture, or the environment. However, broad or subjective applicability criteria may result in routine low-risk activities being brought under IBC review despite being effectively managed through existing institutional safety, training, inspection, and compliance programs.

Expanding IBC oversight in this manner may divert committee time and expertise away from research involving significant biological hazards, where biosafety review provides the greatest benefit. More precise applicability criteria would improve consistency across institutions, reduce unnecessary administrative burden, and ensure that IBC resources remain focused on activities presenting meaningful biosafety concerns.

Section 2. Transgenic Animals and Other Research Models

Comment

The draft policy does not clearly explain how certain categories of research, including some transgenic animals and other genetically modified research models, align with the stated objective of overseeing activities that may pose a risk to human health, animal health, agriculture, or the environment. As written, it is unclear whether oversight is intended to be triggered by demonstrated biological risk or by broad categories of biological manipulation.

NIH should clarify the rationale and review expectations for transgenic animals and other commonly used research models that may present minimal biological risk. The final policy should provide additional guidance, examples, and appropriate exclusions that distinguish activities requiring formal biosafety review from those whose hazards are negligible, well understood, or effectively controlled through established laboratory practices.

Rationale

Many commonly used research models, including certain transgenic insects, established transgenic animal strains, laboratory-adapted organisms, and other well-characterized genetically modified systems, may present little or no meaningful biosafety risk despite potentially falling within broadly defined categories covered by the policy.

Similarly, other activities, such as work involving biological toxins without clearly defined risk thresholds, may create uncertainty regarding whether oversight is intended to be based on actual hazard or merely the presence of a particular material or technology. Without clearer risk-based criteria, institutions may devote substantial review effort to activities with minimal biosafety implications while applying inconsistent standards across institutions.

A framework that more clearly links oversight requirements to demonstrable biological risk would improve consistency, preserve IBC resources for higher-risk research, and better align implementation of the policy with its stated public health and biosafety objectives.

3. Institutional Assurance, Governance, and Authority

Comment

The draft policy appears to make NIH approval of an institutional assurance a prerequisite for conducting covered research; however, the requirements for assurance approval, maintenance, renewal, institutional governance, and compliance accountability are not clearly defined. The policy should provide greater clarity regarding assurance content, approval criteria, review timelines, continuity of research activities, and institutional responsibilities.

NIH should establish transparent standards for assurance review and approval, clearly define institutional roles and authorities, and provide mechanisms that allow research activities to continue during assurance renewals, updates, or federal review periods.

Rationale

Institutions must have a clear understanding of the requirements necessary to establish and maintain compliance. Without defined approval criteria and timelines, institutions may face uncertainty regarding whether research activities can proceed, continue, or be modified. Delays in assurance approval or differing interpretations of institutional responsibilities could create inconsistencies among institutions and unnecessarily disrupt research operations. Clearly defined governance expectations would promote uniform implementation while strengthening institutional accountability.

4. Transparency, Public Posting, and Redaction

Comment

The draft policy would substantially expand requirements for public posting of IBC-related information, including committee records, procedures, incident information, membership information, and other institutional documents. While transparency is an important objective, the current proposal does not clearly define limits on public disclosure or establish consistent standards for protecting personal information, proprietary information, security-sensitive information, or information associated with ongoing investigations.

NIH should establish standardized national redaction requirements, clearly define what information must be publicly disclosed, and provide exclusions or protections for information that could compromise privacy, security, intellectual property, research integrity, or personal safety. The final policy should carefully balance public transparency with the need to protect individual researchers, biosafety personnel, institutional officials, and IBC members from unnecessary exposure through publicly accessible records.

Rationale

Transparency requirements should strengthen public trust without discouraging candid reporting, committee participation, or institutional self-assessment. Without consistent standards, institutions may take significantly different approaches to disclosure, resulting in unequal public access, increased administrative burden, and potential exposure of sensitive information.

In addition to concerns regarding privacy and proprietary information, expanded public posting requirements may create risks for individuals associated with controversial or highly visible areas of research. Publicly accessible information may increase the likelihood of online harassment, intimidation, doxxing, or targeting of researchers, biosafety personnel, institutional officials, and IBC members by individuals or groups opposed to particular research activities. These concerns are particularly relevant in an environment where personal information can be rapidly disseminated and amplified through social media and other online platforms.

NIH should ensure that transparency requirements promote public accountability while providing appropriate safeguards for individuals participating in the oversight and conduct of research. Clear national guidance regarding redaction, disclosure limitations, and protection of personally identifiable information would improve consistency across institutions while balancing transparency with legitimate privacy, security, and safety considerations.

5. Review Categories and Delegated Review

Comment

The draft policy establishes multiple review pathways, including NIH review, full IBC review, and delegated review; however, the boundaries between these categories are not always clear and may overlap. As written, institutions could reasonably reach different conclusions regarding which review pathway applies to the same activity. In addition, several review categories appear to encompass broad classes of biological materials or technologies without clearly explaining the risk-based criteria used to determine the appropriate level of oversight.

NIH should provide objective review-category criteria, decision trees, representative examples, and clear eligibility requirements that allow institutions to consistently determine when NIH review, full IBC review, or delegated review is required. The final policy should also clarify how overlapping categories should be reconciled and clearly explain the risk-based rationale for assigning research activities to different levels of review. Requirements should be distinguished from recommendations, and reviewer qualifications, documentation expectations, and escalation criteria should be clearly defined.

Rationale

Institutions must be able to classify research activities consistently and defensibly. The current framework creates uncertainty because individual research activities may fit within multiple review categories simultaneously, making it difficult to determine the appropriate review pathway. This ambiguity may result in inconsistent implementation across institutions, duplicate reviews, or assignment of comparable research activities to different levels of oversight.

In addition, several review categories appear to expand oversight based on the presence of certain biological materials, organisms, or forms of biological manipulation rather than on clearly articulated biological risk. This raises broader questions regarding whether oversight is intended to be risk-based or category-based. Without clearer distinctions and risk-based criteria, institutions may devote substantial review effort to activities with minimal biosafety implications while applying inconsistent standards to similar research.

A clearer framework that links review requirements to demonstrable biological risk would improve consistency, reduce administrative burden, facilitate appropriate use of delegated review, and allow IBC resources to remain focused on research activities requiring the greatest level of scientific and biosafety scrutiny.

6. Novel, Emerging, and Zoonotic Agents

Comment

The draft policy appears to require additional NIH involvement when organisms, agents, or biological materials lack established Risk Group classifications or containment recommendations. However, the process for obtaining federal determinations, the information required for submission, and expected review timelines are not clearly described.

NIH should establish a transparent process for evaluating novel, emerging, or previously uncharacterized biological agents, including submission requirements, review timelines, expedited pathways where appropriate, and expectations for institutional oversight while federal determinations are pending.

Rationale

Research involving emerging biological agents often occurs under circumstances where timely scientific evaluation is important. Without clearly defined review processes and timelines, institutions may experience uncertainty regarding research initiation, containment expectations, and compliance obligations. Transparent review pathways would improve predictability while ensuring appropriate oversight of emerging biological risks.

7. Incident Reporting

Comment

The draft policy expands institutional incident reporting requirements but does not sufficiently define key terms such as "incident," "compliance violation," "potential release," or "potential laboratory-acquired infection." The policy should provide clearer criteria regarding what events must be reported, when reports are required, and what information should be included.

NIH should establish risk-based reporting thresholds, reporting timelines, report-content requirements, and representative examples of reportable and non-reportable events. Requirements should focus on events that present meaningful biosafety concerns while minimizing duplicative reporting obligations.

Rationale

Incident reporting systems are most effective when reporting requirements are clear, consistent, and focused on events that provide meaningful opportunities for risk reduction and institutional learning. Broad or ambiguous reporting requirements may lead to inconsistent reporting practices, administrative burden, and uncertainty regarding compliance obligations. Greater clarity would improve the quality and usefulness of reported information while supporting national biosafety oversight objectives.

8. Workload, Resources, and Implementation

Comment

The draft policy would substantially increase institutional responsibilities related to protocol review, public disclosure, incident reporting, training, recordkeeping, information management, and oversight of activities not currently subject to review under the NIH Guidelines. The proposed implementation timeline may not provide sufficient time for institutions to revise governance structures, update electronic systems, develop procedures, train personnel, and review existing research activities.

NIH should provide a phased implementation schedule, grandfathering or transition provisions for currently approved research, model guidance documents, standardized training resources, and implementation tools that support consistent adoption across institutions.

Rationale

Successful implementation of a policy of this scope requires substantial institutional planning and resource allocation. Without adequate transition time and implementation support, institutions may face significant compliance challenges while attempting to maintain ongoing research operations. A phased implementation approach would promote higher-quality compliance, reduce operational disruption, and improve consistency across institutions while allowing NIH to address implementation questions that emerge during the transition period.

175. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Purpose and program identity
Policy reference Section I
The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.
Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation
Policy reference Section II
Coverage and decision rules
The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered. You may consider applying this only to NIH funded work.
Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.
Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement

or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.
Implementation period
The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.
Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. NIH implementation responsibilities and coordination
Policy reference Section III D
The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.
Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.
4. NIH review and containment determinations
Policy reference Section IV 1 with related petition provisions in Section III B
The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.
Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 3. IBC establishment functions and operations
Policy reference Section III B
Formal establishment and independent authority
The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.
Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language. The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.
As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent

biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program

administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

3. Continued utility of Risk Groups: 3. Risk assessment and specialized materials
Policy reference Sections V A through V E
The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.
Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.
Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): 1. Investigator responsibilities and voluntary reporting
Policy reference Section III C
The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.
Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.
Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The template for IBC meeting minutes is very extensive. Listing all of this information in the meeting minutes seems unnecessary as all of this information is already in the IBC protocol which IBC member already reviews and meeting minutes are captured at the time of review. The meeting minutes should stick to any controversial issues, the vote, etc. Committee members can always go back and review the protocol to review the information. Posting of the project details on a website also exposes the potential scooping of someone's work as well as potential security risks when all pathogens needs to be listed, etc. It is suggested that the template be consolidated to only require the vote and discussion and a small summary of the purpose of the study rather than an extensive explanation of what is occurring.

6. Other feedback relevant to this resource: 2. Institutional accountability and Biosafety Assurances
Policy reference Section III A
Accountability and minimum program support
The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.
Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions.
Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.
Assurance submission approval and renewal
A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.
Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.
Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.
Requests for consideration. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.
Public disclosure and record retention
The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.
Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.
Incident thresholds investigations and reporting
The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-

failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.
Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.
Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.
Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

1. IBC review pathways and clinical oversight
Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B
Category boundaries and continuing review
Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.
Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals. You may want to consider getting rid of the term de novo review to avoid confusion. Are annual reviews required and what is what required for an annual review – can this be accomplished through an inspection, etc.
Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.
Proposed designated member review procedure
Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent. In the draft Policy it appears that the policy is limited to only research involving "biomedical research, in laboratory settings, involving biohazards". If this is the care, the title of the policy and intent should be consistent with the directive or mission and the directive is a policy for biomedical research: "NIH's mission is to seek fundamental knowledge about the nature and behavior of living systems and the application of that knowledge to enhance health, lengthen life, and reduce illness and disability.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting animals, plants, agriculture, or the environment that in turn affect human health. This narrower scope is difficult to reconcile with the One Health approach and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

Broaden the scope to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of human, animal, plant, and environmental hazards while minimizing

administrative burden; or limit the scope explicitly to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Comment: Clarify the “known or potential risk to human health” threshold for Policy scope

NIH should clarify how the “known or potential risk to human health” threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a “potential risk to human health,” or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight. Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment: The definition of “genetic modification” expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving “known or potential risk to human health.” Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an

expansion of review, or both.

Suggested regulatory text (new exemption, or a note to Section IV-3):
Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3. IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. Adopt this structure in the final Policy or, if declined, explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequence. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of “known or potential risk to human health” applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. I recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.

Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

Human health cannot be considered independently of animal, agricultural, and environmental health. A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety policy should recognize these interconnected pathways.

Oversight should focus on the genetic modification and its credible consequences. The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

Existing animal-use oversight does not replace biosafety review. IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

Oversight should be coordinated across applicable authorities. Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

Institutional biosafety risk assessment: Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:
the nature and stability of the genomic modification;
whether the modification is heritable and the potential for transmission through breeding;
effects on animal health, phenotype, host range, susceptibility, or disease;
potential entry into breeding or food-production systems;
potential environmental release or interaction with non-research animal populations;
whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and
applicable federal, state, or other regulatory oversight.

Delegated review under Section IV-3: Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

Full IBC review under Section IV-2: Full IBC review should apply when the modification presents credible

higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

NIH or other federal review, as applicable: Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:
Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. I request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Policy Section II, Definitions

Comment:

The draft policy needs to define "biohazard" in the definitions section of the policy.

The draft policy uses the term “biological agent,” which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy’s scope extends well beyond select agents. We recommend replacing “biological agent” with “infectious microorganism or biological material,” consistent with Biosafety in Microbiological and Biomedical Laboratories (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

The draft policy uses the term “adventitious agents” in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with “primary cells that may be contaminated by adventitious agents”; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, “may be contaminated” could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3’s delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not deliberately introduced and is not part of the planned research; (2) replace “may be contaminated” in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

The phrase “potential risk to human health” is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. I recommend that NIH define “potential risk to human health” as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy’s scope or again make it a One Health approach and include animal, plant, environment disease that affects human health.

State explicitly that the Policy does not address non-biological hazards.

Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

The draft policy does not define “Transgenic animal.” We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal’s genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal’s genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

The proposed definition of “prion,” as misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals, is inconsistent with the Policy’s scope. It references neurodegenerative disease “in humans or animals,” whereas the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy’s scope, or address animal disease consistently across all agent types.

The proposed definition of “Toxins” should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka “sensitizers”).

Define “peptide” as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

Retain reassortment and non-transgenic methods within the “genetic modification” definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

Define “gene drive modified organisms” and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

Define “shedding” for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of “shedding, replicating, or integrating,” and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA’s Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes

shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate, and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

Use of "Universal Precautions" in clinical research settings. The draft states "However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection." We recommend revising the sentence to use current, risk-based infection-prevention terminology (Standard Precautions) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The Policy as drafted fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. NIH needs to clearly define the requirements, roles, and responsibilities of a BSO or a person who would take on the roles of a BSO as it relates to this proposed policy implementation and IBC oversight. As currently written, the policy ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

NIH and its partners need to define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.
While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at containment level BSL-2; therefore, leaving a large oversight gap. I recommend that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the aforementioned qualifiers.
The draft policy also adds additional regulatory burden on individuals taking on certain roles listed in the Functions section requiring substantial work including:
Periodic inspections
Incident response and investigation
24-hour notification
30-day reporting to NIH
Delegated review
Technical advice
Petitions to NIH
Enhanced reporting of IBC minutes

Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct

access to leadership/authority to support the identification and escalation of unresolved risks. I recommend a broad statement of qualifications rather than a mandatory degree or credential. Please consider the below proposed language:

The BSO or individual taking on roles similar, shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:
Education in the biological or physical sciences, with knowledge of microbiology and molecular biology; demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;
working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO, or designated role, has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the individual's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and SME and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered. It is recommended that each institution describe the following in its institutional plans/policies:

The BSO's, or individual taking on the role, reporting line has direct access to the Institutional Official and senior leadership;
access to all research spaces and records subject to the Policy;
authority to identify and escalate unresolved risks to the IBC and institutional leadership;
independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:
Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
Serving as a permanent voting IBC member and not restricted to certain work at the institution and, where permitted, as a designated or delegated reviewer;

Developing and delivering biosafety and biosecurity training;
Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
Assist with developing emergency response plans;
Coordinating with occupational health on medical surveillance and post-exposure response;
Advising on biosecurity, inventory, and material transfer;
Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.
Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to this financial burden, NIH should provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to each institutions leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. I recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must

therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. I encourage NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

3. Continued utility of Risk Groups: Comment: Risk Groups should not serve as a classification that drives laboratory oversight

I recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Rationale:
Risk Groups describe risk to healthy adults in the community. Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.

They reflect community exposure, not laboratory conditions. Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.

They have no baseline for novel constructs. Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.

They cover only human etiologic agents. Biohazards and biological material is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.

They are misinterpreted. Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

The terms are not interchangeable. Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.

The BMBL does not assign RGs. It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.

Comment: The role of "and any other applicable Federal, State, or local entities" is unclear. NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.

Comment: The scope of the petition requirement is unclear. As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.

Comment: Determinations should be published and reusable. Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. I ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): revamp the incident reporting template (see comments below)

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Comment: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While I support appropriate transparency regarding significant biosafety incidents and institutional responses, I strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, deidentified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment: Limit public content to information that supports transparency

NIH should not require public disclosure of:
Investigator's names
Grant numbers or internal project numbers
Sensitive animal research information
Select agent and toxin information
Proprietary materials and research outcomes
Identifying facility information
Other details that could compromise safety, security, including personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property, research information and national security over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements. It can be done and can be done securely.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual or quarterly Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when

redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4
Biosafety Level
Engineering Barrier Architecture
Incident Risk & Containment Impact
BSL-3 / ABSL-3
Primary containment (BSC/sealed cup) combined with directional negative airflow and 100% exhaust, and at times through HEPA filtration.
A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4
(Suit Lab)
Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.
A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure.
Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

Anchor 'Release' to Containment Boundaries: Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.

Calibrate by Biosafety Level: Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.

Define 'Exposures' and 'Medical Treatment': Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).

Eliminate Subjective Phrasing: Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, I propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

Release (Loss of Containment or Occupational exposure): Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

Incident: A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

6. Other feedback relevant to this resource: Comment: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment: Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research

Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Reference basis: Draft NIH Biosafety Policy, Section V-E; NOT-OD-26-112 implementation-resource statement. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7, and Appendix G-II-C-5.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: While oversight will cover all laboratory biohazards (wild-type pathogens, toxins, prions, etc.), untreated cells, tissues. fluids, and blood of human origin are not specifically addressed and may lead to confusion with the OSHA Bloodborne Pathogen Standard and DOT shipping requirements. We already oversee use of these materials on our campus but I can foresee the argument that, while not mentioned in the new NIH Biosafety Policy, they may argue the research is exempt from oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

182. TERRIE RIFE

I am responding: On behalf of myself

Name: TERRIE RIFE

Name of Organization: James Madison University

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Molecular Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: It is clear to me that plants must fit into an oversight policy. We as humans eat them and do not want to eat plants that have been modified without the appropriate checks being done to know that they are safe. Thus, I don't completely understand why we are taking plants out of the policy without having another policy in place to oversee them.

In general the more clear that the definitions of what should be included in this policy are the better. I like that it is a bit more broad in scope but people should be allowed time to implement these policies and have them approved. Things like writing an assurance and taking the time to change into this new policy will take time and I don't want to see work of any individual faculty member slowed by administrative processes that need to happen for approval.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I am worried that you are not making a policy for all institutions. I see middle size institutions as likely being highly effected as they do not have as many resources as do larger institutions but likely have a variety of research happening so things like requiring a centralized Environmental Health and Safety Office may not be scalable at these institutes and able to accommodate all of the additional researchers and their students. They will have just enough resources to make things feel problematic but not enough to have easy access to resources to change their general policies. Smaller institutions will likely struggle too to implement the new systems although will likely have problems as well without the resources and personal to properly implement all of the layers of things that must happen in order for the researchers to meet the guidelines.

To do many of the things this policy asks for requires a larger infrastructure and probably a few more people. Where do the funds and money come to do this at smaller institutions that don't have excessive funds as this NIH policy expands to include more researchers.

Electronic systems for collecting data will need to be expanded and many changes will need to be made so time and resources for accomplishing this is a problem that needs some addressing.

Committee membership will need to change. None of this is bad, but will require time and resources. Giving smaller schools a bit more time to implement these changes would be helpful.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I am a bit worried about making incident reports public. I think its okay to ask for numbers of incident reports from a given institution and the general nature of those incidents and put that into the public scope but we should be careful about not pushing so much information out there that the public becomes generally more worried about what we are doing because information is more freely available. There is a certain type of incident that yes the public may need to know the nature of it in order to remain safe but most small spills in the lab are just things that happen. I think you will get less reporting of them because you are asking for them to be public rather than more reporting and that is not good. The incidents should be reported so that if there is a problem it can be addressed.

6. Other feedback relevant to this resource: Generally make sure that appropriate amount of time is given for this. Having people available to answer questions as Universities begin to implement these policies.

183. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Life sciences research in higher education.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Define the boundary of the policy:
The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define "biohazard." The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define "biohazard" and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology:
The definition of "biological agent" is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage:
The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk:

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses "prions and other self-aggregating proteins" in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability:
"Biomedical research" should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals:
NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Create a clear precedence rule:
Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight:
Delegated review is a welcome modernization, but requiring every approval to be reported "in full" at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee's role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities:
Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances:
Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during

environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable:
NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Continued utility of Risk Groups: Retain Risk Groups as a starting point
Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change:
The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment:
A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Align accountability with authority:
The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies:
The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately:

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements:
A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting:
Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules:
If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types:
The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Preserve the clearer federal reporting thresholds:
CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories:
The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." The policy should clarify whether precautionary post exposure prophylactic treatment is considered "agent-specific treatment". It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish

administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview:
NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting:
The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

6. Other feedback relevant to this resource: Provide a minimum 24-month phased implementation period:
The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates:
NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources:
Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance:
The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures,

workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models:
The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Uploaded File: CSHEMA-NIH-Comments-1.pdf

Description: To Whom It May Concern: I am submitting this comment in response to the National Institutes of Health (NIH) effort to modernize and strengthen the oversight of biosafety. I support the comment submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA) regarding this effort. CSHEMA's comment appropriately reflects the needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs. As an individual, a biosafety officer working in higher education, my work would be directly impacted by a new NIH policy on biosafety and I support the recommendations outlined by CSHEMA. Given the lack of comprehensive definitions, multiple contradictions, and limited clarity in the proposed policy, it is challenging for institutions to have a full grasp of the level of impact this new doctrine will have. I humbly request that the NIH consider offering second draft for stakeholder review and comment before issuing the final policy. Thank you for the opportunity to comment.

Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards

Response to NOT-OD-26-112

October 12, 2026

Submitted Electronically

The Campus Safety, Health, and Environmental Management Association (CSHEMA) is the premier association for environmental health and safety leadership in higher education. CSHEMA represents institutions that range from large research-intensive universities with mature biosafety programs to smaller colleges that may have limited or no dedicated biosafety staff. Our members include biosafety professionals, environmental health and safety practitioners, and institutional leaders responsible for implementing biosafety requirements across diverse research and teaching environments.

CSHEMA appreciates NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions. **Due to such uncertainty in the final requirements, CSHEMA encourages NIH to provide an opportunity for public review and comment on the next draft before it is finalized.**

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." The policy should clarify whether precautionary post exposure prophylactic treatment is considered "agent-specific treatment". It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

6. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

CSHEMA recommends that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

Conclusion

CSHEMA supports NIH's goal of modernizing biosafety oversight and appreciates the draft's movement toward broader risk awareness, clearer incident thresholds, delegated review, and national safety learning. For the policy to succeed, however, modernization must strengthen the institutional systems that perform biosafety work rather than simply expand their obligations.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified

local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

CSHEMA respectfully requests that NIH revise the draft consistent with these recommendations, release complete implementation materials for public review, pilot key templates and processes, and provide a minimum 24-month phased implementation period. CSHEMA welcomes continued engagement and would be pleased to assist NIH in testing implementation resources or gathering additional institutional perspectives.

Sincerely,

Robin Izzo
President
Campus Safety, Health, and Environmental Management Association

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Developmental Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The new policy exempts plant research from biohazard review. I'd like a clarification about this part of the policy. Is algal research also exempt, and what about research on phytoplankton/diatoms and other photosynthetic organisms that are not infectious towards humans or other animals?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: feedback-on-proposed-NIH-Policy_shared.docx

The unification of oversight for all research involving biohazards, whether or not such research involves recombinant or synthetic nucleic acid technology, is a positive change and one that supports a more comprehensive and cohesive institutional biosafety program. The addition of a Delegated Review mechanism is another positive change, which reduces the burden on IBCs, while providing institutions with the flexibility to define the Delegated Review process in a way that ensures appropriate oversight of lower-risk activities at individual institutions. We support these notable policy improvements.

While many aspects of the draft Policy represent improvements, there are several changes that are likely to have significant negative consequences, as well as points that would benefit from clarification. We respectfully submit the comments below for consideration to further improve the Policy.

1. New incident reporting requirements have an expanded scope of what counts as an incident in addition to the requirement to post all incident reports on a public website.

    a. **Impact:** These changes are expected to have a significant negative impact. The trust that biosafety programs have built up over the years in supporting researchers and encouraging people to report accidents will be eroded by fear of negative ramifications and/or retaliatory action. Even if reporting is anonymized and only a PI or supervisor name is included in the published report, there is a perceived risk of that information being used against the person, lab, and/or institution. People will be less likely to report accidents, which increases the risks associated with untreated injuries or exposures to hazardous materials.

    b. **Recommendation 1**: Individual incident reports should not be publicly posted. Reporting should be to NIH, where data on incidents can be aggregated and trends analyzed and/or reported in a way that removes institutional affiliation to further anonymize individuals involved in an incident. That allows for analysis of the data and identification of trends, which would be a valuable resource to the community, while avoiding negative consequences on the individual, lab, or institution, which would, in turn, undermine the value of the incident reporting process.

    c. **Recommendation 2**: If institutions must be required to publicly post incident information, allow an aggregated annual report. Such an approach could be modeled after OSHA's Form 300A (Summary of Work-Related Injuries and Illnesses). We would strongly recommend this approach for incidents defined by this Policy, which would not be reported to NIH but would be reported to the IBC.

2. The draft Policy states that IBC approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required. It further lists failure to maintain IBC approval as a reportable incident.

    a. **Impact:** The expected impacts of these changes are a significantly increased administrative burden and unintentional non-compliance. In the absence of a specified term limit, many institutions adopted internal policies that require IBC approval to be renewed within a 5-year period, which also coincides with the length of many grants supporting the approved research activities. Switching to a shorter 3-year renewal cycle presents a significant increase in committee workload. Additionally, well-intentioned PIs may face unexpected emergencies, or their registration renewal may come at a time when they are burdened with high workloads from teaching and/or other institutional responsibilities. Because there is no mechanism described in the draft Policy for allowing extensions to PIs facing extenuating circumstances, failure to renew an IBC registration on time would result in a reportable incident of non-compliance.

    b. **Recommendation 1:** Keep a defined term limit on IBC approval but increase the term of IBC approval to 5 years.

    c. **Recommendation 2:** Empower IBCs to exercise judgement and flexibility in granting reasonable, one-time extensions to PIs facing extenuating circumstances and/or moving a registration renewal to a different time of year so as not to conflict with other high-workload periods.

3. The draft Policy states that research with primary cells that may be contaminated by adventitious agents requires IBC review and approval under Section IV-2. We interpret this new scope to mean that any primary human cell line, tissue, or clinical specimen with an unknown status (has not been tested for bloodborne pathogens or other infectious agents) will have to go to the IBC for approval, whereas none of this material required IBC review previously. Instead, this material fell under the OSHA Bloodborne Pathogens Standard, which requires institutions to establish oversight mechanisms that have worked for many decades.

    a. **Impact**: This change is expected to have a significant negative impact. The increased burden on most IBCs will be enormous, with no apparent benefit, since the existing mechanisms to comply with the OSHA Bloodborne Pathogens Standard must still be maintained. This is an unnecessary duplication of oversight, and the increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation**: Allow this type of material to be approved via the new Delegated Review process described in Section IV-3 rather than requiring IBC

review. That would allow institutions flexibility to integrate existing biosafety oversight mechanisms into the Delegated Review process defined by the new Policy.

4. The draft Policy states that research involving genetically modified cells, viruses, or organisms, other than plants requires IBC approval and approval under Section IV-2. Previously, a large portion of genetically modified cell lines were considered exempt under Section III-F-8, Appendix C-I. For many IBCs, that type of material made up the majority of genetically modified material, and because it was considered exempt and did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely and in accordance with the OSHA Bloodborne Pathogens Standard. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8, Appendix C-I now falls under Section IV-2 and requires full committee review.

    a. **Impact**: This change is expected to have a <u>significant negative impact</u>. This will create an enormous new burden on IBCs, with no apparent benefit because the main risk associated with material that fell under Section III-F-8, Appendix C-I was the risk of adventitious agents or bloodborne pathogens, as mentioned in point 3 above. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation**: Retain the Section III-F-8, Appendix C-I exemption, or allow materials that would have fallen under Section III-F-8, Appendix C-I to be approved via the Delegated Review process described in Section IV-3.

5. The draft Policy's definition of a genetic modification includes introduction into cells, organisms, or viruses of stable alterations into the genome by passaging. It is not clear what passaging activity falls within the Policy scope. Simply culturing an organism in vitro will lead to accumulation of undefined genetic alterations and could be considered passaging. Cultures that are maintained in a lab are also considered to be passaged through the process of sub-culturing to create multiple stocks from an original sample. Further, most of the time, growing an organism in vitro or in a model system selects for mutations that optimize growth in a lab environment, not in a human host, and these lab-adapted strains typically lose virulence or pathogenicity. The Influenza A/Puerto Rico/8/1934 (H1N1) strain (often called PR8 influenza) is a classic, mouse-adapted laboratory strain of the influenza A virus isolated from a human patient in Puerto Rico in 1934. It is an example of a strain that is a lower risk option for studying influenza. These examples of passaging generally have not required IBC review. In the draft Policy, all of these activities would require IBC review and approval under Section IV-2 (see also point 4 above).

a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because most passaging does not increase the risk of the agent or associated research activities. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

b. **Recommendation**: We recommend refining the scope of the definition of genetic modifications by defining passaging as the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile. Examples of passaging activities that should be included in Section IV-2 include passaging with the intent or likelihood for an agent to acquire a new virulence trait or antibiotic resistance or to adapt a pathogen to a new host species and/or tissue tropism.

6. In the draft Policy, the definition of genetic modification that falls within the scope of the policy now includes modification via chemical or radiological means. Further, the draft Policy requires the IBC to review all genetically modified cells under Section IV-2 (see also point 4 above). The main risk associated with use of chemical or radiological agents to create mutations is in the handling of the chemical or radiological material, not necessarily in handling the cells once the mutagen has been removed. There are separate regulations that apply to chemical and radiological hazards. The use of chemical and radiological hazards is best handled by the respective safety experts who are familiar with the appropriate regulations and safety requirements, not the IBC. Assessment of the risks of these mutagens are outside of the scope of an IBC, since IBC members typically have little to no expertise on chemical or radiological hazards.

    a. **Impact**: This is a vast expansion of scope that will duplicate oversight and increase burden on IBCs, without a clear benefit. Further, the IBCs typically lack appropriate expertise for evaluating the risks associated with these mutagens. The increased burden on IBCs will detract attention from higher-risk matters, which do fall within the expertise of the committee.

    b. **Recommendation**: Remove chemical and radiological means from the definition of genetic modifications that fall within the scope of the policy and defer oversight to existing regulations that apply to the use of chemical and radiological hazards. Alternatively, refine the scope to apply to experiments in which the mutagenic agent is combined with the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile, as recommended for passaging in point 5 above.

7. The draft policy states that research with genetically modified RG1 biological agents requires Delegated Review under Section IV-3. Previously, most standard cloning and/or

protein expression with *E. coli* and other model host-vector systems were considered exempt under Section III-F-8, and it did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely with proper waste disposal procedures. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8 now requires Delegated Review.

a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. The increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

b. **Recommendation 1**: We strongly recommend retaining existing III-F-1 through III-F-8 exemptions.

c. **Recommendation 2**: Furthermore, and supported by decades of safe research experience, we also recommend expanding the exemptions to include other low-risk cloning and protein expression research in model organisms such as *E. coli* BL21 strains, *C. elegans*, and *Drosophila*.

8. The draft Policy states that research conducted with transgenic organisms at BSL-1/ABSL-1" requires Delegated Review. Previously, almost all breeding or purchasing of transgenic rodents was exempt under Section III-F-8, Appendix C-VII and was not typically registered with an IBC at all. Instead, oversight of those transgenic rodents typically has been handled through federally mandated Institutional Animal Care and Use Committees (IACUCs) that have biosafety professionals as members who conduct risk assessments and suggest risk mitigation measures as part of that review process. Many IBCs do not even have a mechanism for tracking this information. Additionally, many researchers using transgenic mice are not using any other sort of biological material; the research is often focused on behavioral studies or pre-clinical studies that fall outside the scope of an IBC. A very large proportion of transgenic animal work is done with transgenic rodents and zebrafish, and almost all of that work poses no new risk compared to the unmodified rodents and zebrafish.

    a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. Again, the increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

    b. **Recommendation 1**: We strongly recommend retaining the III-F-8, Appendix C-VII exemption and allow existing oversight of these low-risk animals to continue via the IACUC.

c. **Recommendation 2**: As mentioned in point 7 above, we also recommend expanding the exemptions to include other low-risk transgenic model organisms such as zebrafish, *C. elegans* and *Drosophila*.

9. The draft Policy defines biological agents that fall within the scope as bacteria, viruses, fungi, or parasites that cause human disease. This definition seems to contradict the draft Policy's requirement for Delegated Review of research with genetically modified RG1 biological agents (see point 7 above). Risk Group 1 agents are not associated with disease in healthy adult humans. Some agents may be considered opportunistic pathogens, but there is currently no list of RG1 organisms that are considered opportunistic pathogens.

    a. **Recommendation 1:** NIH should clarify the nature of biological agents that fall within the scope of the Policy. We recommend that the Policy scope is limited to pathogenic biological agents that cause disease in humans, including opportunistic pathogens but excluding non-pathogenic agents.

    b. **Recommendation 2**: As there is no list of RG1 agents, and the list of RG2 agents is incomplete, we further recommend empowering the IBCs, Biosafety programs, and PIs to make the determination of RG1 and RG2 for biological agents that are not currently listed in Appendix B of the NIH Guidelines or the BMBL using the risk assessment guidance provided therein.

10. The draft Policy's definition of a genetic modification includes introduction of materials that can be transcribed or translated. This would include materials such as purified or synthetic miRNAs, snRNAs, shRNAs, and mRNAs, which are transient in nature and may lead to changes in gene expression but do not replicate and do not modify or integrate into the genome. Work with such materials was previously exempted under III-F-1 but would now fall under Section IV-2 and require IBC review and approval.

    a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create a significant new burden on IBCs, with no apparent benefit given that no genetic modifications are made with these materials. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation:** We recommend retaining the III-F-1 exemption and removing these materials from the scope of the Policy.

11. The scope of the draft Policy includes prions and self-aggregating proteins, and research activities involving these materials would require IBC review and approval. We support the draft Policy as it pertains to prions, but request refinement of the oversight pertaining to self-aggregating proteins. IBC oversight should not extend automatically to every protein capable of self-aggregation. Protein aggregation is common in biology and,

by itself, does not establish an infectious or exposure hazard. Oversight should instead focus on proteins or protein assemblies for which there is credible evidence that an aggregated conformer can act as a persistent, self-propagating seed; induce conformational conversion of the corresponding native protein; spread between cells or tissues; and transmit pathology following experimental exposure or inoculation. We recommend the following risk-assessment approach, which is consistent with the BMBL principle that containment decisions should be protocol-driven rather than based only on an agent's name.

a. **Recommendation 1:** Classical mammalian prions and prion-containing tissues should remain categorically within IBC purview because of their established infectivity, potential for serious disease, environmental persistence, and resistance to conventional inactivation procedures.

b. **Recommendation 2:** Seed-competent aggregates of α-synuclein, including preformed fibrils, amplified seeds, and α-synuclein-containing material derived from affected human or animal tissue, should also be subject to IBC review because α-synuclein assemblies have demonstrated prion-like templating, cellular and anatomical propagation, and experimental transmissibility in animal models. Inclusion under IBC oversight should not be understood to mean that α-synuclein is known to be naturally communicable between people or that it presents the same level of hazard as a classical prion.

c. **Recommendation 3:** Other self-aggregating proteins should be evaluated individually rather than be included in Section IV-2 of the draft Policy solely because they form oligomers, fibrils, or amyloid. Relevant considerations should include evidence of experimentally transmissible pathology, persistence of seeding activity, resistance to standard decontamination, source and concentration of the material, route and scale of exposure, use of human- or animal-derived pathological tissue, and procedures involving inoculation, sharps, aerosols, or other opportunities for occupational exposure. Routine work with non-seed-competent monomeric proteins or aggregates lacking evidence of biological propagation would not ordinarily require specialized biosafety review beyond the requirements otherwise applicable to the experimental system, and we recommend that the Delegated Review mechanism described in Section IV-3 be applied to such work.

12. The scope of the draft Policy includes toxins listed as Select Agents, and research activities involving these materials would require IBC review and approval under Section IV-2, while research with biological toxin proteins not on the Select Agent list may be approved by Delegated Review under Section IV-3. We support this overall approach; however, we request refinement of the Policy with the following recommendations.

a. **Recommendation 1:** Allow research activities using exempt amounts of Select Agent toxins to be approved by Delegated Review. Most institutions have already developed effective internal biosafety oversight mechanisms for handling these exempted materials. Integrating those internal oversight mechanisms into the Delegated Review process would allow IBCs to focus on the higher-risk Select Agent work.

b. **Recommendation 2:** Either publish a list of biological toxins that fall within the scope of the Policy or use a threshold toxicity value as a risk-based factor for determining whether a biological toxin requires oversight by the Policy. We further recommend that biological toxins that have an LD_{50} greater than 1000 µg/kg be exempt from this Policy.

13. The scope of the draft Policy includes cells, viruses, or organisms, other than plants, that have been genetically modified. It is assumed that animals are included as organisms, but it is not clear what is considered an animal under this Policy.

    a. **Recommendation:** Use a definition of animal that is consistent with the Guide for the Care and Use of Laboratory Animals, which has been adopted by the NIH Office of Laboratory Animal Welfare, and which defines animals as any vertebrate animal (i.e., traditional laboratory animals, agricultural animals, wildlife, and aquatic species) produced for or used in research, testing, or teaching.

14. The draft Policy indicates that the effective date will be 6 months from publication of final Policy, and that applicability includes ongoing work. It is unclear how ongoing work will be impacted by the new review and approval requirements. Work that was not subject to IBC oversight according to the NIH Guidelines may have been approved via voluntary institutional biosafety oversight mechanisms.

    a. **Impact:** Work that was approved by a Biosafety Officer (or other institutional biosafety oversight) and now requires a higher level of review by the IBC would need to cease until IBC approval is obtained. This would have a significant negative impact on a large number of projects that are suddenly subject to new oversight, thereby wasting grant money and setting back important research projects.

    b. **Recommendation:** Require activities that have not received approval by a Biosafety Officer or other institutional biosafety oversight mechanism to be reviewed and approved according to the final Policy within 6 months of the publication of the final Policy. For activities that have received approval by a Biosafety Officer or other institutional biosafety oversight mechanism, allow the existing approval to remain in place until such time as de novo registration is

required (see point 2 regarding our recommendation to allow 5-year term limits for IBC registration approvals).

RE: The Draft NIH Biosafety Policy for Research Involving Biohazards

The Committee on Assessment of Biohazards and Embryonic Stem Cell Research Oversight (CAB/ESCRO) is the Institutional Biosafety Committee (IBC) at the Massachusetts Institute of Technology and was formed in January of 1975 to ensure the safe and responsible conduct of biological research at MIT. The CAB/ESCRO appreciates the opportunity to provide feedback on the Draft NIH Biosafety Policy for Research Involving Biohazards that will replace the current NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules.

The unification of oversight for all research involving biohazards, whether or not such research involves recombinant or synthetic nucleic acid technology, is a positive change and one that supports a more comprehensive and cohesive institutional biosafety program. The addition of a Delegated Review mechanism is another positive change, which reduces the burden on IBCs, while providing institutions with the flexibility to define the Delegated Review process in a way that ensures appropriate oversight of lower-risk activities at individual institutions. We support these notable policy improvements.

While many aspects of the draft Policy represent improvements, there are several changes that are likely to have significant negative consequences, as well as points that would benefit from clarification. We respectfully submit the comments below for consideration to further improve the Policy.

1. New incident reporting requirements have an expanded scope of what counts as an incident in addition to the requirement to post all incident reports on a public website.

    a. **Impact:** These changes are expected to have a significant negative impact. The trust that biosafety programs have built up over the years in supporting researchers and encouraging people to report accidents will be eroded by fear of negative ramifications and/or retaliatory action. Even if reporting is anonymized and only a PI or supervisor name is included in the published report, there is a perceived risk of that information being used against the person, lab, and/or

institution. People will be less likely to report accidents, which increases the risks associated with untreated injuries or exposures to hazardous materials.

b. **Recommendation 1**: Individual incident reports should not be publicly posted. Reporting should be to NIH, where data on incidents can be aggregated and trends analyzed and/or reported in a way that removes institutional affiliation to further anonymize individuals involved in an incident. That allows for analysis of the data and identification of trends, which would be a valuable resource to the community, while avoiding negative consequences on the individual, lab, or institution, which would, in turn, undermine the value of the incident reporting process.

c. **Recommendation 2**: If institutions must be required to publicly post incident information, allow an aggregated annual report. Such an approach could be modeled after OSHA's Form 300A (Summary of Work-Related Injuries and Illnesses). We would strongly recommend this approach for incidents defined by this Policy, which would not be reported to NIH but would be reported to the IBC.

2. The draft Policy states that IBC approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required. It further lists failure to maintain IBC approval as a reportable incident.

   a. **Impact:** The expected impacts of these changes are a <u>significantly increased administrative burden and unintentional non-compliance.</u> In the absence of a specified term limit, many institutions adopted internal policies that require IBC approval to be renewed within a 5-year period, which also coincides with the length of many grants supporting the approved research activities. Switching to a shorter 3-year renewal cycle presents a significant increase in committee workload. Additionally, well-intentioned PIs may face unexpected emergencies, or their registration renewal may come at a time when they are burdened with high workloads from teaching and/or other institutional responsibilities. Because there is no mechanism described in the draft Policy for allowing extensions to PIs facing extenuating circumstances, failure to renew an IBC registration on time would result in a reportable incident of non-compliance.

   b. **Recommendation 1:** Keep a defined term limit on IBC approval but increase the term of IBC approval to 5 years.

   c. **Recommendation 2:** Empower IBCs to exercise judgement and flexibility in granting reasonable, one-time extensions to PIs facing extenuating circumstances and/or moving a registration renewal to a different time of year so as not to conflict with other high-workload periods.

3. The draft Policy states that research with primary cells that may be contaminated by adventitious agents requires IBC review and approval under Section IV-2. We interpret this new scope to mean that any primary human cell line, tissue, or clinical specimen with an unknown status (has not been tested for bloodborne pathogens or other infectious agents) will have to go to the IBC for approval, whereas none of this material required IBC review previously. Instead, this material fell under the OSHA Bloodborne Pathogens Standard, which requires institutions to establish oversight mechanisms that have worked for many decades.

    a. **Impact**: This change is expected to have a significant negative impact. The increased burden on most IBCs will be enormous, with no apparent benefit, since the existing mechanisms to comply with the OSHA Bloodborne Pathogens Standard must still be maintained. This is an unnecessary duplication of oversight, and the increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation**: Allow this type of material to be approved via the new Delegated Review process described in Section IV-3 rather than requiring IBC review. That would allow institutions flexibility to integrate existing biosafety oversight mechanisms into the Delegated Review process defined by the new Policy.

4. The draft Policy states that research involving genetically modified cells, viruses, or organisms, other than plants requires IBC approval and approval under Section IV-2. Previously, a large portion of genetically modified cell lines were considered exempt under Section III-F-8, Appendix C-I. For many IBCs, that type of material made up the majority of genetically modified material, and because it was considered exempt and did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely and in accordance with the OSHA Bloodborne Pathogens Standard. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8, Appendix C-I now falls under Section IV-2 and requires full committee review.

    a. **Impact**: This change is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because the main risk associated with material that fell under Section III-F-8, Appendix C-I was the risk of adventitious agents or bloodborne pathogens, as mentioned in point 3 above. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

b. **Recommendation**: Retain the Section III-F-8, Appendix C-I exemption, or allow materials that would have fallen under Section III-F-8, Appendix C-I to be approved via the Delegated Review process described in Section IV-3.

5. The draft Policy's definition of a genetic modification includes introduction into cells, organisms, or viruses of stable alterations into the genome by passaging. It is not clear what passaging activity falls within the Policy scope. Simply culturing an organism in vitro will lead to accumulation of undefined genetic alterations and could be considered passaging. Cultures that are maintained in a lab are also considered to be passaged through the process of sub-culturing to create multiple stocks from an original sample. Further, most of the time, growing an organism in vitro or in a model system selects for mutations that optimize growth in a lab environment, not in a human host, and these lab-adapted strains typically lose virulence or pathogenicity. The Influenza A/Puerto Rico/8/1934 (H1N1) strain (often called PR8 influenza) is a classic, mouse-adapted laboratory strain of the influenza A virus isolated from a human patient in Puerto Rico in 1934. It is an example of a strain that is a lower risk option for studying influenza. These examples of passaging generally have not required IBC review. In the draft Policy, all of these activities would require IBC review and approval under Section IV-2 (see also point 4 above).

    a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because most passaging does not increase the risk of the agent or associated research activities. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation**: We recommend refining the scope of the definition of genetic modifications by defining passaging as the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile. Examples of passaging activities that should be included in Section IV-2 include passaging with the intent or likelihood for an agent to acquire a new virulence trait or antibiotic resistance or to adapt a pathogen to a new host species and/or tissue tropism.

6. In the draft Policy, the definition of genetic modification that falls within the scope of the policy now includes modification via chemical or radiological means. Further, the draft Policy requires the IBC to review all genetically modified cells under Section IV-2 (see also point 4 above). The main risk associated with use of chemical or radiological agents to create mutations is in the handling of the chemical or radiological material, not necessarily in handling the cells once the mutagen has been removed. There are separate regulations that apply to chemical and radiological hazards. The use of chemical and radiological hazards is best handled by the respective safety experts who are familiar with the appropriate regulations and safety requirements, not the IBC.

Assessment of the risks of these mutagens are outside of the scope of an IBC, since IBC members typically have little to no expertise on chemical or radiological hazards.

a. **Impact**: This is a vast expansion of scope that will duplicate oversight and increase burden on IBCs, without a clear benefit. Further, the IBCs typically lack appropriate expertise for evaluating the risks associated with these mutagens. The increased burden on IBCs will detract attention from higher-risk matters, which do fall within the expertise of the committee.

b. **Recommendation**: Remove chemical and radiological means from the definition of genetic modifications that fall within the scope of the policy and defer oversight to existing regulations that apply to the use of chemical and radiological hazards. Alternatively, refine the scope to apply to experiments in which the mutagenic agent is combined with the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile, as recommended for passaging in point 5 above.

7. The draft policy states that research with genetically modified RG1 biological agents requires Delegated Review under Section IV-3. Previously, most standard cloning and/or protein expression with *E. coli* and other model host-vector systems were considered exempt under Section III-F-8, and it did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely with proper waste disposal procedures. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8 now requires Delegated Review.

   a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. The increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

   b. **Recommendation 1**: We strongly recommend retaining existing III-F-1 through III-F-8 exemptions.

   c. **Recommendation 2**: Furthermore, and supported by decades of safe research experience, we also recommend expanding the exemptions to include other low-risk cloning and protein expression research in model organisms such as *E. coli* BL21 strains, *C. elegans*, and *Drosophila*.

8. The draft Policy states that research conducted with transgenic organisms at BSL-1/ABSL-1" requires Delegated Review. Previously, almost all breeding or purchasing of transgenic

rodents was exempt under Section III-F-8, Appendix C-VII and was not typically registered with an IBC at all. Instead, oversight of those transgenic rodents typically has been handled through federally mandated Institutional Animal Care and Use Committees (IACUCs) that have biosafety professionals as members who conduct risk assessments and suggest risk mitigation measures as part of that review process. Many IBCs do not even have a mechanism for tracking this information. Additionally, many researchers using transgenic mice are not using any other sort of biological material; the research is often focused on behavioral studies or pre-clinical studies that fall outside the scope of an IBC. A very large proportion of transgenic animal work is done with transgenic rodents and zebrafish, and almost all of that work poses no new risk compared to the unmodified rodents and zebrafish.

a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. Again, the increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

b. **Recommendation 1**: We strongly recommend retaining the III-F-8, Appendix C-VII exemption and allow existing oversight of these low-risk animals to continue via the IACUC.

c. **Recommendation 2**: As mentioned in point 7 above, we also recommend expanding the exemptions to include other low-risk transgenic model organisms such as zebrafish, *C. elegans* and *Drosophila*.

9. The draft Policy defines biological agents that fall within the scope as bacteria, viruses, fungi, or parasites that cause human disease. This definition seems to contradict the draft Policy's requirement for Delegated Review of research with genetically modified RG1 biological agents (see point 7 above). Risk Group 1 agents are <u>not</u> associated with disease in healthy adult humans. Some agents may be considered opportunistic pathogens, but there is currently no list of RG1 organisms that are considered opportunistic pathogens.

    a. **Recommendation 1:** NIH should clarify the nature of biological agents that fall within the scope of the Policy. We recommend that the Policy scope is limited to pathogenic biological agents that cause disease in humans, including opportunistic pathogens but <u>excluding</u> non-pathogenic agents.

    b. **Recommendation 2**: As there is no list of RG1 agents, and the list of RG2 agents is incomplete, we further recommend empowering the IBCs, Biosafety programs, and PIs to make the determination of RG1 and RG2 for biological agents that are not currently listed in Appendix B of the NIH Guidelines or the BMBL using the risk assessment guidance provided therein.

10. The draft Policy's definition of a genetic modification includes introduction of materials that can be transcribed or translated. This would include materials such as purified or synthetic miRNAs, snRNAs, shRNAs, and mRNAs, which are transient in nature and may lead to changes in gene expression but do not replicate and do not modify or integrate into the genome. Work with such materials was previously exempted under III-F-1 but would now fall under Section IV-2 and require IBC review and approval.

    a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create a significant new burden on IBCs, with no apparent benefit given that no genetic modifications are made with these materials. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation:** We recommend retaining the III-F-1 exemption and removing these materials from the scope of the Policy.

11. The scope of the draft Policy includes prions and self-aggregating proteins, and research activities involving these materials would require IBC review and approval. We support the draft Policy as it pertains to prions, but request refinement of the oversight pertaining to self-aggregating proteins. IBC oversight should not extend automatically to every protein capable of self-aggregation. Protein aggregation is common in biology and, by itself, does not establish an infectious or exposure hazard. Oversight should instead focus on proteins or protein assemblies for which there is credible evidence that an aggregated conformer can act as a persistent, self-propagating seed; induce conformational conversion of the corresponding native protein; spread between cells or tissues; and transmit pathology following experimental exposure or inoculation. We recommend the following risk-assessment approach, which is consistent with the BMBL principle that containment decisions should be protocol-driven rather than based only on an agent's name.

    a. **Recommendation 1:** Classical mammalian prions and prion-containing tissues should remain categorically within IBC purview because of their established infectivity, potential for serious disease, environmental persistence, and resistance to conventional inactivation procedures.

    b. **Recommendation 2:** Seed-competent aggregates of α-synuclein, including preformed fibrils, amplified seeds, and α-synuclein-containing material derived from affected human or animal tissue, should also be subject to IBC review because α-synuclein assemblies have demonstrated prion-like templating, cellular and anatomical propagation, and experimental transmissibility in animal models. Inclusion under IBC oversight should not be understood to mean that α-synuclein is known to be naturally communicable between people or that it presents the same level of hazard as a classical prion.

c. **Recommendation 3:** Other self-aggregating proteins should be evaluated individually rather than be included in Section IV-2 of the draft Policy solely because they form oligomers, fibrils, or amyloid. Relevant considerations should include evidence of experimentally transmissible pathology, persistence of seeding activity, resistance to standard decontamination, source and concentration of the material, route and scale of exposure, use of human- or animal-derived pathological tissue, and procedures involving inoculation, sharps, aerosols, or other opportunities for occupational exposure. Routine work with non-seed-competent monomeric proteins or aggregates lacking evidence of biological propagation would not ordinarily require specialized biosafety review beyond the requirements otherwise applicable to the experimental system, and we recommend that the Delegated Review mechanism described in Section IV-3 be applied to such work.

12. The scope of the draft Policy includes toxins listed as Select Agents, and research activities involving these materials would require IBC review and approval under Section IV-2, while research with biological toxin proteins not on the Select Agent list may be approved by Delegated Review under Section IV-3. We support this overall approach; however, we request refinement of the Policy with the following recommendations.

    a. **Recommendation 1:** Allow research activities using exempt amounts of Select Agent toxins to be approved by Delegated Review. Most institutions have already developed effective internal biosafety oversight mechanisms for handling these exempted materials. Integrating those internal oversight mechanisms into the Delegated Review process would allow IBCs to focus on the higher-risk Select Agent work.

    b. **Recommendation 2:** Either publish a list of biological toxins that fall within the scope of the Policy or use a threshold toxicity value as a risk-based factor for determining whether a biological toxin requires oversight by the Policy. We further recommend that biological toxins that have an LD_{50} greater than 1000 µg/kg be exempt from this Policy.

13. The scope of the draft Policy includes cells, viruses, or organisms, other than plants, that have been genetically modified. It is assumed that animals are included as organisms, but it is not clear what is considered an animal under this Policy.

    a. **Recommendation:** Use a definition of animal that is consistent with the Guide for the Care and Use of Laboratory Animals, which has been adopted by the NIH Office of Laboratory Animal Welfare, and which defines animals as any vertebrate animal (i.e., traditional laboratory animals, agricultural animals, wildlife, and aquatic species) produced for or used in research, testing, or teaching.

14. The draft Policy indicates that the effective date will be 6 months from publication of final Policy, and that applicability includes ongoing work. It is unclear how ongoing work will be impacted by the new review and approval requirements. Work that was not subject to IBC oversight according to the NIH Guidelines may have been approved via voluntary institutional biosafety oversight mechanisms.

    a. **Impact:** Work that was approved by a Biosafety Officer (or other institutional biosafety oversight) and now requires a higher level of review by the IBC would need to cease until IBC approval is obtained. This would have a significant negative impact on a large number of projects that are suddenly subject to new oversight, thereby wasting grant money and setting back important research projects.

    b. **Recommendation:** Require activities that have not received approval by a Biosafety Officer or other institutional biosafety oversight mechanism to be reviewed and approved according to the final Policy within 6 months of the publication of the final Policy. For activities that have received approval by a Biosafety Officer or other institutional biosafety oversight mechanism, allow the existing approval to remain in place until such time as de novo registration is required (see point 2 regarding our recommendation to allow 5-year term limits for IBC registration approvals).

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Some scope of work requiring IBC review is not well defined, and these definitions should be tied to biosafety hazard.
-Research with prions or other self-aggregating proteins
-Research with well-characterized cell lines
-Primary cells that may be contaminated by adventitious agents.
It is unclear if this would include ALL work with primary human cells or NHP cells or tissues.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It is uneccessary to publically post incident reports along with PI and funding information. This will decrease the amount of reporting.

Meeting minutes template is way too long and overdetailed. Most of the information is not important to each meeting.

6. Other feedback relevant to this resource: Research that was previously exempt from IBC review under NIH Guidelines Section F now appears to require IBC review and approval prior to initiation, including work with all transgenic organisms and plasmids. This need additional clarification as it would require anyone working at an institution to have an IBC protocol.

Bethesda, MD 20892

Re: Notice Number: NOT-OD-26-112

Request for Information: Draft NIH Biosafety Policy for Research Involving Biohazards

Dear Dr. Jorgenson,

The Biotechnology Innovation Organization (BIO) appreciates the opportunity to provide comments on the National Institutes of Health (NIH) Draft Biosafety Policy for Research Involving Biohazards. BIO and our member companies share NIH's commitment to ensuring that biomedical research is conducted safely, responsibly, and securely. Strong biosafety practices are essential to protecting researchers and the public, maintaining confidence in the biomedical research enterprise, and ensuring that the United States remains prepared to respond to biological threats.

BIO is the premier biotechnology advocacy organization representing biotech companies, industry leaders, and state biotech associations in the United States and more than 35 countries around the globe. BIO members range from biotech start-ups to some of the world's largest biopharmaceutical companies, all united by the same goal: to develop medical and scientific breakthroughs that prevent and fight disease, restore health, and improve patients' lives. BIO membership includes companies developing vaccines, therapeutics, diagnostics, and other medical countermeasures (MCMs) to prevent, detect, and respond to naturally occurring infectious diseases and chemical, biological, radiological, and nuclear threats.

MCM research presents a particularly important consideration for the proposed Policy. Research involving pathogens is often necessary to understand biological threats and to develop the vaccines, therapeutics, and diagnostics required to protect Americans from them. Federal biosafety policy must therefore appropriately manage legitimate biological risk while preserving the ability of responsible entities to conduct necessary research into innovations that could mitigate those same threats.

BIO supports NIH's objective of modernizing biosafety oversight and establishing risk-based safeguards. However, the proposed expansion of the NIH Guidelines into a substantially broader policy governing research involving biohazards raises important questions regarding

scope, applicability, duplication with existing oversight frameworks, and the potential effect on U.S. biotechnology competitiveness. BIO recommends NIH more narrowly and clearly define the research and entities subject to the Policy, establish explicit mechanisms to avoid duplicative oversight, and ensure that requirements are proportionate to the risks presented by individual research activities.

Scope and Definitions Must Be Clear, Risk-Based, and Operationally Workable

The proposed Policy represents a significant expansion from the current NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules. The draft Policy would apply to all biomedical research in laboratory settings involving defined biohazards and would expand oversight to wild-type biological agents that cause human disease, genetically modified cells, viruses and organisms, toxins, prions, and other covered materials.

BIO recommends that NIH further refine this scope before finalizing the Policy.

Terms that determine whether research falls within a federal oversight framework must provide sufficient specificity for researchers and companies to determine their obligations prospectively. Definitions such as “biomedical research,” “biohazard,” “potential risk to human health,” and “genetically modified” could encompass an overly broad range of research routinely conducted safely throughout the biotechnology sector.

This is particularly relevant to MCM development. By its nature, MCM research may involve pathogens, pathogen components, genetically modified systems, challenge models, primary cells, platform technologies, or other biological materials necessary to characterize threats and evaluate potential countermeasures. The presence of one of these materials should not by itself establish that research presents a level of biosafety risk warranting heightened oversight. One key example of potential risk to non-recombinant work with wild-type biological agents would be routine research involving wild-type seasonal influenza viruses to evaluate yearly vaccine candidates. This research would become subject to new Institutional Biosafety Committee (IBC) review and approval requirements under the Policy’s proposed Section IV-3, even when conducted under established biosafety protocols. Such requirements could introduce additional administrative burdens without necessarily improving biosafety outcomes and slow down critical research needed to protect Americans every year from a very common biological threat.

BIO recommends that NIH narrow and clarify the proposed Policy’s scope to ensure that oversight is proportionate to the actual biosafety risks associated with specific research activities, rather than broadly capturing research based solely on the biological materials involved. NIH should establish clear, scientifically grounded definitions and risk-based criteria that distinguish non-risky biomedical research from activities warranting heightened oversight. This approach would be consistent with the protocol-driven risk assessment principles that have long underpinned U.S. biosafety practice.

NIH Should Clarify Which Private Sector Entities and Research Activities Are Subject to the Policy

BIO is particularly concerned about the proposed applicability of the Policy. As currently drafted, the Policy states that it applies to NIH-supported research regardless of funding level or mechanism, as well as non-NIH funded research conducted at an institution receiving any NIH funding. The latter is particularly problematic due to the unwarranted expansion of the Policy's scope to research funded independently of the agency, potentially imposing duplicate or conflicting oversight obligations and discouraging private sector partnerships with NIH-funded institutions. NIH should clarify how this provision would operate for biotechnology companies and complex public-private research arrangements.

Biotechnology research increasingly occurs through networks of companies, academic collaborators, contract research organizations, contract development and manufacturing organizations, clinical research organizations, government laboratories, and other partners. A biotechnology company may participate simultaneously in NIH-supported research, privately financed product development, BARDA-supported MCM programs, Department of War programs, and FDA-regulated clinical development. It is therefore important that NIH clearly define the organizational boundaries of an "institution" for purposes of the Policy and explain whether receipt of NIH funding for one discrete program could subject unrelated or privately funded research elsewhere within a company or corporate organization to NIH oversight. BIO recommends NIH establish a clear nexus between NIH funding and research subject to the Policy. NIH should avoid creating circumstances in which receipt of a single NIH award effectively extends NIH jurisdiction across an organization's unrelated research portfolio. Without greater clarity, companies may face substantial uncertainty regarding whether accepting NIH funding for one research program creates additional complexities including compliance requirements for other research activities. For many innovators, especially small and emerging biotechnology companies, this uncertainty may become a factor in determining whether to seek or accept NIH funding.

Oversight Should Be Proportionate to Risk Rather Than Predicated on the Presence of a Covered Biological Material

BIO proposes NIH maintain a risk-based approach to oversight, reporting, and review requirements. However, a risk-based framework is only effective if low and moderate risk research can move efficiently through the system and if categories are sufficiently clear to produce consistent outcomes across institutions. The proposed Policy would require IBC review for a broad range of activities, including research involving genetically modified cells, viruses or organisms, Risk Group 3 and 4 (RG3 and RG4) wild-type agents, certain primary cells, and certain clinical research. Delegated review would also be required for activities including RG2 wild-type agents, well-characterized cell lines, genetically modified RG1 agents, and certain plasmids and vectors. The breadth of these categories could significantly increase the volume of research requiring IBC review without necessarily producing a commensurate improvement in biosafety.

BIO recommends NIH establish clearer exclusions or streamlined pathways for well-characterized research activities where risks are already understood and effectively managed. The goal should be to concentrate limited biosafety expertise and institutional resources on

research presenting meaningful risk rather than expanding administrative review across large categories of routine biomedical research. This is particularly important for MCM developers, where speed and continuity of research can directly affect national preparedness.

Avoid Layering Duplicative Requirements Across the Federal Research Enterprise

Biotechnology companies already operate within an extensive system of federal and institutional requirements governing research safety, biosecurity, clinical development, laboratory practices, research involving recombinant or synthetic nucleic acids, select agents and toxins where applicable, human and animal research, and FDA-regulated product development.
BIO appreciates that the draft Policy recognizes that research under the regulation or purview of another federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained. This principle should be strengthened and operationalized. NIH should establish clear reciprocity and reliance mechanisms identifying when existing federal review satisfies corresponding requirements under the Policy. Companies should not be required to conduct duplicative assessments, submit identical information to multiple federal entities, or undergo multiple institutional reviews addressing the same underlying biosafety risk. Duplicative oversight increases already substantial administrative costs and resources away from biosafety activities and can delay critical research without improving safety outcomes.

Federal agencies should also work toward common terminology, risk assessment methodologies, documentation requirements, and reporting expectations. This is especially important as the U.S. Government continues to update multiple policies affecting biological research. A succession of overlapping requirements, each individually intended to strengthen safety or security, can collectively create substantial administrative burden and uncertainty if they are not harmonized. BIO recommends recognizing existing mature biosafety programs and allowing flexibility for institutions to demonstrate equivalent governance, risk assessment, and oversight processes.

The appropriate objective should be an integrated federal framework in which requirements complement rather than duplicate one another. The delegated review provisions that already exist should remain appropriately limited to clearly defined low-risk activities.

Protect Proprietary, Security-Sensitive, and Confidential Research Information

BIO also encourages NIH to carefully evaluate the proposed transparency requirements for IBC materials and incident reporting. Transparency can strengthen confidence in biosafety oversight, but biotechnology research frequently involves proprietary information, confidential development programs, sensitive intellectual property, and information with potential biosecurity implications.

Public disclosure requirements should therefore be narrowly tailored to the public safety purpose they are intended to serve and include clear protections for proprietary, confidential, security-sensitive, and prepublication scientific information.

Companies should not be required to choose between participating in federally supported research and protecting commercially sensitive technologies or information that should not be broadly disseminated for security reasons. If commercially sensitive information does not have robust protections, companies would be unlikely to participate in federally supported research.

Biosafety Policy Must Strengthen, Rather Than Weaken, U.S. Biotechnology Competitiveness

Biosafety and U.S. economic competitiveness should be mutually reinforcing objectives. The United States has historically led biomedical innovation because of its combination of world-class research institutions, innovative biotechnology companies, strong intellectual property protections, sophisticated capital markets, and productive partnerships between government, academia, and industry. Federal biosafety policy should preserve these advantages.

Biomedical R&D is increasingly global. Research programs, investment, scientific talent, and partnerships can move between jurisdictions. If U.S. requirements become significantly more complex, costly, uncertain, or time-consuming than those of international competitors without a corresponding improvement in safety, the United States risks discouraging domestic research and investment and ceding ground as the leader in biotechnological research and development.

This risk is particularly consequential for MCM research. Many MCM programs already face challenging economics because products intended for rare biological threats have limited traditional commercial markets. Additional fixed compliance costs, delays, and uncertainty can have an outsized effect on decisions to initiate or continue these programs. Moreover, innovators developing platforms for MCMs could transition their technology to another indication with more certainty and less risk.

For small biotechnology companies, even modest increases in research timelines and compliance costs can affect capital requirements and investment decisions. Over time, these cumulative burdens can reduce the number of companies willing to conduct research on high-consequence pathogens and emerging infectious diseases. Such an outcome would not improve U.S. biosecurity. It could instead reduce domestic expertise, weaken the MCM pipeline, and shift strategically important research capabilities to jurisdictions where the United States has less visibility and influence. Ultimately, this could delay the development of lifesaving MCMs, leaving Americans more vulnerable to an evolving biothreat landscape.

NIH should therefore evaluate the economic and competitiveness impacts of the proposed Policy as part of its implementation process, including effects on small and mid-sized companies, participation in federally supported research, MCM development timelines, and the location of biotechnology R&D.

Recommendations

BIO recommends that NIH revise the draft Policy to:

1. Narrow and clarify the definitions that determine the Policy's scope, particularly “biomedical research,” “biohazard,” “potential risk to human health,” “genetically modified,” and “institution.”

2. Establish a clear nexus between NIH funding and research subject to NIH oversight so that receipt of NIH funding for one program does not automatically bring unrelated privately funded research within scope.

3. Preserve a genuinely risk-based approach in which the level of oversight is determined by the specific risks presented by an experiment rather than the presence of a covered biological material.

4. Create exclusions or expedited review mechanisms for well-characterized, lower-risk research.

5. Establish formal reliance and reciprocity mechanisms for research already subject to appropriate oversight by FDA, BARDA, the Department of War, or other federal entities.

6. Conduct a specific assessment of the Policy's impact on MCM research and development and ensure that implementation does not undermine federal objectives to expand the domestic MCM industrial base.

7. Provide flexible compliance mechanisms and technical assistance for small and emerging biotechnology companies, including access to external or shared IBC resources.

8. Ensure public transparency requirements contain strong protections for proprietary, confidential, intellectual property, and security-sensitive information.

9. Harmonize the Policy with existing and emerging federal biosafety, biosecurity, research security, and product development requirements to prevent duplicative or inconsistent compliance obligations.

10. Evaluate the cumulative economic and competitiveness effects of the Policy, including whether additional requirements could discourage domestic investment or move strategically important research outside the United States.

Conclusion

BIO supports NIH’s goal of modernizing the nation’s biosafety framework and ensuring that biomedical research is conducted safely, securely, and responsibly. Achieving that objective requires a framework that is scientifically grounded, proportionate to risk, operationally feasible, and coordinated with the broader federal research and regulatory enterprise.

These principles are especially important for medical countermeasure research. The United States depends on biotechnology companies willing to conduct difficult, capital-intensive research against biological threats for which traditional commercial markets may not exist.

Federal policy should encourage responsible participation in this research while applying appropriate safeguards, not create cumulative barriers that unintentionally reduce the number of organizations willing or able to undertake it.

Clear definitions, targeted oversight, regulatory harmonization, and practical implementation can strengthen biosafety while preserving the innovation ecosystem necessary for U.S. biodefense and national health security. BIO looks forward to working with NIH to develop a final policy that protects the American public while maintaining U.S. leadership in biomedical innovation and medical countermeasure development.

BIO appreciates the opportunity to submit comments in response to this RFI and looks forward to partnering with NIH as the agency aims to modernize and strengthen biosafety policies to keep pace with the evolving biothreat landscape.

Sincerely,

/s/

Phyllis Arthur

Executive Vice President, Chief of Global Health

Dear National Institutes of Health Office of Science Policy,

The New York State Department of Health Wadsworth Center appreciates the opportunity to comment on the National Institutes of Health (NIH) Draft Policy for Research Involving Biohazards and supports NIH's efforts to strengthen biosafety oversight through a risk-based approach that reflects the nature of the research being conducted.

Please see the attached comments and recommendations regarding the NIH Draft Biosafety Policy.

Sincerely,

Dr. Leonard Peruski

Director, Wadsworth Center

Attachment: NYSDOH Wadsworth Center Comments on Draft Policy for Research Involving Biohazards

1. RFI Questions
   a. *Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed*.

      Comment #1: The current definition of biomedical research leaves some uncertainty about what research activities are covered. Public health laboratories conduct applied research to improve the testing and detection of agents of public health concern, a critical activity for effectively responding to emerging biological and chemical threats. These activities directly support public health response efforts and should not unintentionally trigger additional research oversight requirements that could delay implementation of needed testing.

      Recommendation: NIH should clarify the definition of biomedical research to distinguish applied research conducted as part of Public Health Laboratory operations from research intended to be covered by the policy, making it clear that test development and improvements performed in Public Health Laboratories are outside the scope of the policy.

      Comment #2: The term "biohazard" should be clearly defined under General Definitions with the other key terms used in the policy, not in Section II – Scope.

      Recommendation: NIH should define "biohazard" under General Definitions. We offer the following definition for consideration: Biohazard - Any of the following biological agents or materials that cause disease in humans or otherwise have known or potential risk to human health: 1) wild-type biological agents,i.e., virus, bacteria, fungi, or parasites; 2) cells, biological agents, or organisms, other than plants, that have been genetically modified; 3) toxins, prions, and other self-aggregating proteins; or 4) cells or organisms, other than plants, containing biological agents or materials from categories 1, 2, or 3 above.

   b. *Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL)*.

      Comment #3: The existing risk group classification system as defined in the current NIH Guidelines is too limited in scope to have utility in conducting risk assessments involving communicable agents with potential for risk to the community. The expanded definition of risk groups provided by the World Health Organization goes

further in trying to capture the risk to the community, but it still doesn't adequately account for pathogens with the greatest risk for societal consequences, including pathogens with pandemic potential. As an example, the 1918 H1N1 influenza virus, 1957-1968 H2N2 influenza virus, and H5N1 highly pathogenic avian influenza virus are collectively classified as Risk Group 3 influenza viruses in Appendix G of the current NIH Guidelines, with requirements for BSL-3 enhanced mitigation measures. However, the WHO definition of a risk group 3 pathogens indicates that it "does not ordinarily spread from one infected individual to another" and has "low community hazard". This discrepancy in being able to accurately characterize the relative societal risk of communicable agents using the existing risk group classification systems demonstrates the need for a separate, distinct hazard characterization nomenclature specific to the potential for a communicable wild-type pathogen, or modified pathogens, to cause a negative consequence to society.

Recommendation: Develop a separate, distinct hazard characteristic nomenclature that is specific to determining the relative societal risk of pathogens based on population susceptibility, route of transmission, ability for pre-symptomatic or asymptomatic spreading, treatment options, and other agent hazard characteristics appropriate for conducting a societal risk assessment of communicable pathogens.

c. *Feedback on the implementation resources and areas in which additional guidance would be beneficial*.

Comment #4: The background section of the policy notes that additional information about requirements for containment practices, occupational health plans, and training for research with RG3 influenza viruses (currently articulated in Section II-D-7 and Appendix G-II-C-5 of the NIH Guidelines) will be shared with the research community through implementation resources. However, those mitigation measures are currently limited to high-risk strains of influenza viruses with societal risk.

Recommendation: NIH should ensure that the BSL-3 enhanced mitigation measures currently described in Section II-D-7 and Appendix G-II-C-5 of the current NIH Guidelines serve as default BSL-3 enhanced requirements for RG3 influenza viruses and other communicable pathogens with potential for significant societal consequence unless otherwise determined to be unnecessary by the local IBC in consultation with NIH.

2. Section II – Scope

Comment #5: It is not clear what the authors mean when they state, "Any research subject to this Policy that is also under the regulation or purview of another federal

agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained."

Recommendation: Clarify from whom, specifically, “approvals and other applicable clearances” need to be obtained before research may proceed under the oversight of another federal agency.

3. Section II - General Definitions

Comment #6: The acronym GDMO is used throughout the body of the policy but never defined. Only Gene Drive is defined.

Recommendation: Add Gene Drive Modified Organism (GDMO) to the definitions sections and provide an appropriate definition to supplement the existing definitions provided for Gene Drive and Genetic modification.

Comment #7: Arthropod Containment Levels are not captured in the scope of this policy.

Recommendation: Revise the definition of laboratory research to include arthropod containment facilities as follows: Laboratory research - Research conducted within Biosafety Level/Animal Biosafety Level/Arthropod Containment Level (BSL/ABSL/ACL) 1-4containment facilities, including spaces such as vivarium, core facilities, insectaries, or clinical settings. It does not include the deliberate release of a biohazard outside of biocontainment, such as field release research. Update all references to BSL2/ABSL2, BSL3/ABSL3, etc. throughout the policy to include reference to the applicable ACL, i.e., BSL3/ABSL3/ACL3.

4. Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)

Comment #8: The responsibility described for the 6th bullet unnecessarily repeats part of the 5th bullet.

Recommendation: Revise the first sentence of the 6th bullet as follows, “Petitioning NIH to lower the minimum containment for research involving RG3 and RG4 agents that have not previously been approved by NIH.”

Comment #9: It is misleading to say that the categories of reportable incidents listed under Section II-B all pose a significant risk to human health.

Recommendation: Replace the phrase "that pose a significant risk to human health” with “that have the potential for significant risk to human health" in both the policy and on the incident report form.

Comment #10: The criteria for determining a "potential laboratory-acquired infection" under the reporting requirements are not provided.

Recommendation: Provide specific criteria for what would be considered a "potential laboratory acquired infection" or revise to limit the reporting requirement to confirmed laboratory-acquired infections determined through diagnostic testing.

Comment #11: The wording of the BSL-3/ABSL-3 and BSL-4/ABSL-4 reporting requirement for "potential exposures" should be modified to align with the definition of "occupational exposure" in the select agent regulations for consistency and to eliminate any uncertainty related to potential exposure vs. occupational exposure requiring reporting.

Recommendation: Revise the "exposure" reporting requirement for BSL-3/ABSL-3 and BSL-4/ABSL-4 to read as follows: Any occupational exposure defined as any reasonably anticipated skin, eye, mucous membrane, parenteral contact, or respiratory aerosol exposure to pathogens at BSL-3/ABSL-3/ACL-3 or BSL-4/ABSL-4 that may result from the performance of an employee's duties. Any exposure event that results in the activation of post-exposure medical treatment or surveillance protocols would be considered an occupational exposure. To simplify, the definition of "occupational exposure" could be added to the General Definitions section so that the statement here could be "Any occupational exposure."

Comment #12: The wording of the BSL-3/ABSL-3 and BSL-4/ABSL-4 reporting requirement for releases should be modified to align with the definition of "release" in the select agent regulations for consistency and to eliminate any uncertainty related to "potential releases vs. releases that need to be reported.

Recommendation: Revise the BSL-3/ABSL-3 and BSL-4/ABSL-4 "release" reporting requirement to read as follows, “Any release defined as any discharge of a BSL-3/ABSL-3/ACL-3 or BSL-4/ABSL-4 pathogen outside primary containment devices (e.g., biological safety cabinets, centrifuge safety cups, etc.) or secondary barriers (e.g., HEPA exhaust systems and other biocontainment facility boundaries).” If the definition of "release" is moved to the General Definitions section, the policy can simply say "Any release" under the reporting section.

Comment #13: The wording of BSL-2/ABSL-2 exposure reporting requirements should be aligned with the proposed definition of occupational exposure for BLS-3/ABSL-3/ACL-3 and BSL-4/ABSL-4 exposure reporting.

Recommendation: Revise the BSL-2/ABSL-2 exposure reporting requirement to read as follows, “Any incidents involving occupational exposures at BSL-2/ABSL-2/ACL-3 that require agent-specific post exposure medical treatment beyond basic first aid.”

Comment #14: The BSL-3/ABSL-3 and BSL-4/ABSL-4 reporting expectations for biological agent inventories should use terminology consistent with the select agent program for consistency to avoid uncertainty about what needs to be reported.

Recommendation: Replace the biological agent reporting wording as follows, “Theft or loss of biological agents that may have public health consequences.”

Comment #15: The reporting expectations for "compliance violations" at any BSL/ABSL is too vague and open ended. This reporting expectation needs to be specific to avoid over reporting of minor compliance issues.

Recommendation: Revise the compliance violation reporting requirements to be limited to serious compliance violations associated with this policy, such as 1) failure to obtain or maintain IBC approval; or 2) failure to obtain NIH approval for lowering biocontainment for research.

Comment #16: The wording of the reporting exemption for minor spills of low-risk agents does not specify if the breach is at the primary or secondary containment barrier.

Recommendation: Revise to clarify that the reporting exemption applies to minor spills where a breach of secondary containment is not involved.

Comment #17: The incident report posting requirement states that all incident reports need to be posted on a public facing webpage.

Recommendation: Clarify that only NIH incident reports need to be posted on a public-facing webpage, not “all incident reports”.

Comment #18: The requirement for reporting all incidents within 24 hours or as soon as the institution becomes aware of the incident is an unreasonable expectation (e.g., for an incident that happens at the end of a Friday workday).

Recommendation: Replace the 24-hour reporting requirement with "by the close of the next business day or as soon as the institution becomes aware of the incident".

5. Section IV-1 - Research That Requires NIH and IBC Approval Before Initiation

Comment #19: During the NIH regional listening sessions, it was stated that one of the goals of the biosafety modernization effort was to recalibrate oversight to risk. However, there are clear examples of wild-type pathogens that are known for their pandemic potential (eg., RG3 influenza pathogens currently described in Appendix G of the NIH Guidelines) that are not included under Section IV-1 *Research That Requires NIH and IBC Approval Before Initiation* to ensure that the minimum

biosafety containment, occupational health, and exposure response mitigation measures are in place before the research activities with potential for societal risk can begin.

Recommendation: NIH should reconsider including all laboratory activities that generate, use, reconstitute, or transfer an eradicated or extinct pathogens with pandemic potential (PPP) to Section IV-1, since these PPPs may pose a significant threat to public health, the capacity of health systems to function, or national security and, therefore, warrant Federal oversight to ensure consistency in the mitigation measures being utilized for all laboratory manipulations involving these PPPs.

6. Section V - Risk Assessment and Mitigation for Research Involving Biohazards

   Comment #20: Section V makes no reference to the need for risk-based occupational health programs and post-exposure response protocols when it comes to selecting and establishing mitigation measures for research involving biohazards, particularly those with high risk to individual workers and/or society.

   Recommendation: Add “occupational health programs” and “exposure response protocols” as additional examples of key components of the risk mitigation strategy to emphasize their importance.

7. Section V-A - Requirements and Considerations for Risk Assessment of the Characteristics of the Biohazard

   Comment #21: The statement under Section V-A that "Biological agents that cause disease in humans are classified into four RGs based on pathogen characteristics and population impacts." is somewhat of a false assumption (See comment #3).

   Recommendation: NIH needs to develop a separate, distinct hazard characteristic nomenclature that is specific to determining the relative societal risk of pathogens based on population susceptibility, route of transmission, ability for pre-symptomatic or asymptomatic spreading, treatment options, and other agent hazard characteristics appropriate for conducting a societal risk assessment of communicable pathogens. This new nomenclature should be referenced within this policy as appropriate to communicate its role in facilitating risk assessments.

8. Section V-E - Risk Mitigation Strategies and Laboratory Containment

   Comment #22: The basis for assigning a minimum BSL for experiments involving mutated or recombinant influenza viruses is the RG of the virus that was the source of the of the majority of segments in the virus. However, the current risk group classification system does not adequately characterize the potential societal risk

which may be the key risk factor for determining the need for any enhanced mitigation measures. Additionally, it is not clear why a minimum BSL is being established for mutated or recombinant influenza viruses, but not coronaviruses (e.g., SARS-CoV-1 or SARS-CoV-2 virus) where a similar level of individual worker risk and societal risk could be of concern for research including mutated or recombinant viruses.

Recommendation: Revise the section on minimum BSL criteria to reflect the appropriate societal risk criteria or updated classification system on which these minimum BSL recommendations should be made, not the existing risk group classification system. Additionally, consider expanding the scope of research that requires minimum BSLs to include other communicable pathogens with potential for enhanced societal risk from mutated or recombinant viruses.

Comment #23: The requirement for conducting experiments with viruses containing genes from RG3 influenza viruses with pandemic potential at BSL-3 enhanced containment with the additional requirement for an occupational health plan, does not specify the detailed expectations of these minimum BSL-3 enhanced requirements.

Recommendation: NIH should ensure that the BSL-3 enhanced mitigation measures that will be included in the implementation resources serve as the default requirements for BSL-3 enhanced for RG3 influenza viruses, as well as for other communicable pathogens with potential for significant societal consequence, unless otherwise determined to be unnecessary by the local IBC in consultation with NIH.

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Non-Profit Research Organization

Role: Other

Role - Other: research operations

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Expand the stated purpose: Recommend explicitly including potential risks to the environment and animals to ensure the policy addresses impacts beyond human health.

Clarify self-aggregating proteins: Define “self-aggregating proteins” and provide risk assessment guidance to help institutions determine when additional biosafety oversight is warranted. Clarify whether all relevant proteins can be identified and how institutions should assess proteins with unknown or incompletely characterized properties.

Extend the implementation timeline: Recommend extending the implementation period to 12 months following the effective date to allow institutions sufficient time to evaluate existing programs, revise policies and procedures, restructure responsibilities, and secure additional resources as needed.

Clarify genetic modification by chemical or radiological means: The definition of genetic modification includes “the introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.” Recommend removing or clarifying the references to chemical and radiological means and providing specific guidance on when such activities fall within the policy's scope. Radiological hazards are already subject to separate regulatory oversight, including NRC requirements where applicable. Without clear boundaries, this provision could create duplicative reviews and responsibilities.

Clarify the definition of laboratory research: The policy defines laboratory research as work conducted in BSL/ABSL-1 through BSL/ABSL-4 facilities, including vivarium, core facilities, and clinical settings. Recommend clarifying what qualifies as a “clinical setting.” Clinical areas, such as patient rooms and operating rooms, typically do not have an assigned biosafety level. Guidance is needed to determine when research conducted in these areas falls within the policy's scope.

Clarify clinical research terminology: Define terms such as “shedding” and “higher manipulations” and provide examples to support consistent interpretation across institutions and research settings.

Allow flexibility in IBC meeting documentation: The requirement to prepare and approve IBC meeting minutes no later than the next convened meeting may create additional administrative burden. Recommend clarifying the approval process and allowing reasonable flexibility to accommodate institutional meeting schedules and workflows.

Clarify or reconsider de novo review requirements: Recommend eliminating or limiting de novo reviews when existing institutional review processes adequately address the risks. Requiring de novo review may create a significant administrative burden for IBCs and research teams by necessitating additional assessments, documentation, and approvals for activities that may already have been evaluated under established protocols. This could lead to duplicative reviews, increased processing times, and delays in research activities without a corresponding improvement in biosafety. If de novo review is retained, provide clear criteria defining when it is required and allow institutions to leverage existing risk assessments and approvals when appropriate.

Provide guidance for Biological Risk Groups (RGs): The NIH Guidelines classify agents into four Risk Groups based on their ability to cause disease in healthy adult humans. The BMBL uses risk assessment to inform recommended biosafety levels rather than serving as a comprehensive Risk Group classification list. Recommend developing guidance similar to the existing NIH Risk Group list that institutions can use as a reference. Not all agents included in the NIH Guidelines' Risk Group list are addressed in the BMBL, creating a need for a consistent reference to support institutional assessments.

Clarify Biological Safety Officer (BSO) responsibilities: A single BSO may not be sufficient to support the needs of large or complex institutions, where biosafety responsibilities are often distributed across multiple qualified staff members. Recommend allowing designated responsibilities to be performed by the BSO or an authorized designee to accommodate different institutional structures.

Clarify incident reporting pathways: The policy requires PIs to report incidents but does not clearly identify the appropriate reporting recipient or process. Recommend explicitly identifying the IBC as a reporting contact and clarifying the reporting pathway, including any additional institutional or federal reporting requirements.

Reconsider public-facing incident reporting: Posting incident details on a public-facing website may discourage reporting or undermine a culture of safety by creating concerns about reputational consequences. Recommend evaluating whether public disclosure is necessary and considering alternatives that promote transparency, accountability, and learning while protecting appropriate confidentiality.

Provide flexibility for institutional implementation: Recognize that institutions differ in size, staffing, research complexity, and existing oversight structures. Implementation guidance should allow institutions to establish processes that meet policy requirements without unnecessarily duplicating existing oversight functions.

Clarify whether human and non-human primate materials are in scope: The policy's incident-reporting language references post-exposure treatment for potential adventitious agents, such as non-human primate Herpes B virus or bloodborne pathogens. It is unclear whether this includes research involving human blood, other human materials, or non-human primate materials when no biological agent is deliberately involved in the research. For example, macaque research may involve animal procedures without the deliberate use of biological agents. Recommend clarifying which materials and activities are covered and which incidents require reporting.

Apply risk-based oversight to established transgenic organisms: Recommend clarifying whether routine research involving established transgenic organisms at BSL-1/ABSL-1, such as commonly used transgenic mouse strains and fruit fly lines, requires additional review. Consider exempting established, well-characterized organisms from de novo or additional review when no new hazards are introduced and existing institutional oversight adequately addresses the risks. Additional review could remain necessary when genetic modifications introduce novel or increased hazards.

Clarify reporting expectations for exposures: Distinguish between exposures involving biological agents deliberately used in research and exposures involving potential adventitious agents unrelated to the research. Provide clear examples of which scenarios require institutional reporting, NIH reporting, or both to ensure consistent interpretation and avoid unnecessary reporting.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Establish minimum qualifications and competency standards for the Biosafety Officer (BSO) role: The BSO is a specialized technical role requiring expertise in biosafety principles, biological risk assessment, regulatory requirements, containment practices, and incident investigation. Recommending that any institutional staff member can fulfill this role without defined qualifications or demonstrated competency is not best practice and may compromise the quality of biosafety oversight.

3. Continued utility of Risk Groups: Develop a standardized Risk Group reference to support risk assessments: Risk Group classification is a foundational starting point for biological risk assessment. It helps determine an agent’s potential to cause disease and informs the evaluation of appropriate containment measures and biosafety controls. The NIH Guidelines classify biological agents into four Risk Groups based on their ability to cause disease in healthy adult humans, while the BMBL uses a risk assessment approach to inform recommended biosafety levels rather than providing a comprehensive Risk Group classification list.

Recommend developing and maintaining a reference similar to the existing NIH Risk Group list. Not all agents included in the NIH Guidelines are addressed in the BMBL, creating gaps when institutions evaluate agents not specifically covered by either resource. A standardized reference, supplemented by guidance for unlisted agents, would provide a practical starting point for institutional assessments and reduce administrative burden.

This reference should support—not replace—a thorough, activity-specific risk assessment, as the appropriate biosafety level and controls depend on additional factors, including the nature of the work, route of exposure, procedures performed, and available risk mitigation measures.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Create an incentive for non-funded institutions to comply with this policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Remove PI names from incident reports and public disclosures: Recommend removing the PI's name from incident reports intended for public disclosure and reporting incidents in an aggregated, anonymized format. Incidents are an inevitable part of research, and the primary goal of biosafety oversight should be to understand what happened, identify contributing factors, and implement corrective actions to prevent recurrence. Including the PI's name in public reports can create the perception of assigning blame or singling out individuals, which is inconsistent with a strong, proactive safety culture.

Public identification may discourage PIs and research staff from reporting incidents, near misses, and potential hazards, limiting opportunities to identify trends, address systemic issues, and prevent future injuries or exposures. Effective incident reporting should encourage transparency and continuous improvement rather than create fear of reputational consequences.

Recommend collecting incident data systematically and publishing anonymized, aggregated summaries of incidents, trends, and corrective actions, similar to OSHA's approach to summarizing workplace injury and illness data. This would promote transparency, accountability, and organizational learning while protecting individual identities and encouraging timely reporting. The focus should be on understanding risks and preventing recurrence, not assigning blame.

6. Other feedback relevant to this resource: Increase implementation to 12 months.

I am responding: On behalf of an organization

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As Biosafety professionals, our comments reflect our wet-lab and administrative experience to address practical operational needs for compliance under the new Policy. We appreciate the opportunity to provide feedback.

While we strongly support Delegated Member Review (Section IV-3) to streamline low-risk research, the Policy needs precise definitions. Expanding IBC purview to cover all wild-type RG-2 agents, clinical trials, and non-recombinant toxins significantly increases administrative workload. Without additional qualified Biosafety Officers (BSOs) and support staff, this expanded scope will create severe review bottlenecks. To maintain safety standards without stalling research, NIH should provide robust implementation grace periods and scalable guidance. In addition, rather than mandating rigid templates, NIH should allow institutions to adapt the forms to their existing software, whilst keeping required elements. Reserving full IBC review for higher-risk traits, gene drives, and environmental release ensures resources remain focused on real risk.

For Clinical Trial Oversight Scope (Section IV-2), there appears to be expanded clinical trial review from RG-2 and above agents, to any agent that sheds/replicates. This may create jurisdictional confusion between IBCs and IRBs. NIH must provide in more specific detail with examples of what studies require full IBC review.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): As Biosafety professionals we strongly support the proposed tiered oversight framework, yet the policy needs clearer practical guidance to empower IBCs to perform their risk assessments. Guidance should account for local facility capabilities, personnel expertise, occupational health infrastructure, and community considerations.

Review bottlenecks are a real concern: Section II indicates the Policy will apply to all ongoing research as of the effective date (6-month effective date). Attempting to re-review or retroactively re-classify thousands of active, approved protocols simultaneously will severely overwhelm IBC administrative

capacity, stall ongoing research, and create massive administrative backlogs. The proposed time-frame is insufficient for institutions to overhaul electronic compliance systems, update institutional biosafety manuals, retrain faculty and staff, and reconfigure websites. Even the DOD had to suspend implementation of their Cybersecurity Certification requirements due to compliance costs. NIH should extend the implementation timeline to at least 12 to 18 months from the publication of the final Policy, and incorporate a "grandfathering" clause or transitional exemption for currently approved, active research protocols and well-established models.

3. Continued utility of Risk Groups: Risk Groups (RGs) offer a clear baseline for assessing intrinsic hazard, but the Policy should rely on the Biosafety in Microbiological and Biomedical Laboratories (BMBL) rather than creating another version of a less frequently updated Appendix B of the NIH Guidelines. To prevent delays during public health emergencies or with novel pathogens, local IBCs need explicit authority to provisionally assign temporary containment levels while federal determinations are pending. Restricting direct NIH approval (Section IV-1) to high-risk novel research keeps federal oversight focused on true uncertainties rather than bottlenecking agents (or agent families) with long histories of safe use.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary compliance for non-NIH-funded or international institutions lacks enforcement, allowing unmonitored entities to conduct high-risk research or withhold incident reports without regulatory consequences. Implementing this Policy requires significant administrative effort and at a significant cost (personnel and IT systems), non-funded entities have little incentive to participate voluntarily. To solve this, NIH should establish an accreditation program similar to AAALAC for animal research. Requiring this accreditation for journal publishing, private investment, joint ventures, or international federal funding would incentivize non-funded institutions to adopt NIH-level biosafety standards.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The Draft Minute and Incident Reporting templates should be recommended, not mandated (except for required elements). While pre-made templates can be helpful for general standardization, they constrain workflows. IBC meetings tend to be dynamic and can vary in structure, a rigid template forces discussions to fit a format that doesn't quite match how the meeting unfolds. Additionally, the pre-built templates in IBC and EHS software have technical limitations and constraints that do not match the mandated template; that restricts how IBCs will capture and organize notes effectively.

As Biosafety professionals we fully support transparency and accountability regarding institutional safety, but we have serious concerns regarding the requirement to publicly post all final incident reports on Websites. Specifically, this mandate creates significant risks: 1) Incident investigations inherently involve sensitive details regarding specific physical spaces and personal health information (PHI) of individuals involved. Even with redactions or vagueness, the broad public availability of these details could lead to privacy breaches or discourage complete disclosures. 2) The fear of public exposure is a well-documented deterrent in safety culture. If researchers believe minor or sensitive incidents will be published on a public-facing webpage, it will disincentivize transparent reporting, ultimately undermining the very safety and compliance goals this Policy aims to achieve. 3) There may be a subset of incidents which fall under states' quality assurance privilege laws, with confidentiality protections for certain materials. 4) Our institution already maintains transparency through our IBC meeting minutes, which includes incident reporting which are publicly available on our website and provide adequate

oversight and public awareness without compromising individual privacy or research security. In addition, there are reporting requirements to local public health authorities. 5) Comprehensive incident response and root cause analysis takes time and a 24-hour reporting period is not feasible; this may result in reporting that is speculative and, as a result, of limited value. 6) We recommend striking the requirement for public-facing incident report postings and instead employ a model similar to the OSHA Form 300A, where incidents can be reported in aggregate annually. This satisfies public transparency without compromising safety reporting culture or individual privacy.

6. Other feedback relevant to this resource: The final Policy should require a designated, qualified Biological Safety Officer (BSO) for all institutions conducting biohazard research across all risk levels (RG1–RG4 / BSL-1–BSL-4), rather than limiting mandatory BSOs strictly to BSL-3/BSL-4 or GDMO work. To close "title-only" loopholes where under-qualified staff are assigned BSO duties, NIH implementation guidance must define explicit minimum professional qualifications or offer a formal waiver process for certain qualifying institutions. Given the national shortage of qualified biosafety professionals, the proposed 6-month effective date is impractical for recruiting staff while establishing new incident-reporting and public-posting workflows.

In addition, NIH should extend the implementation timeline to at least 12–18 months while providing training resources, guidance templates, and implementation grants to help institutions build compliant infrastructure.

Thank you for the opportunity to provide our comments.

193. George Mason University

I am responding: On behalf of an organization

Name: Ericka Pearce, IBC Contact and Biosafety Officer on behalf of the George Mason University IBC

Name of Organization: George Mason University

Type of Organization: Institutional Research Oversight Committees e.g. IRB

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): George Mason University, (GMU)

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Public Posting of Incident Reports and Near-Miss Reporting

George Mason University's Institutional Biosafety Committee supports NIH's goal of increasing transparency and modernizing biosafety data collection. However, the requirement to publicly post incident reports represent a significant expansion beyond the current NIH Guidelines and raises concerns related to confidentiality, security-sensitive information, privacy, and the potential impact on institutional reporting culture.

Public Reporting: NIH should clarify expectations regarding redaction of personally identifiable information, proprietary research information, security-sensitive details, and information that could inadvertently identify students and laboratory personnel. Publicly posted reports should include sufficient contextual information regarding risk assessment, corrective actions, and outcomes to reduce the potential for misinterpretation. The value of incident reporting lies not in public attribution of individual events, but in the ability to identify trends, share lessons learned, and strengthen prevention efforts across the research enterprise.

Operational Impact: The potential for public disclosure may discourage timely self-reporting, voluntary disclosure, and open discussion of incidents and lessons learned. The NIH's OLAW reporting framework demonstrates that effective oversight can focus on institutional response, corrective actions, and program improvement rather than public identification of individuals or institutions. A perceived risk of public exposure could have a chilling effect on reporting culture and reduce participation in voluntary reporting programs. Many incidents covered by the draft policy may already be reportable through existing federal mechanisms, including Federal Select Agent Program reporting requirements and CDC or USDA APHIS permit conditions. NIH should seek to leverage existing reporting pathways whenever possible to minimize duplicative reporting and associated administrative burden while still meeting biosafety and oversight objectives.

Recommendation: NIH should further clarify public posting requirements, establish standardized redaction practices, permit reliance on existing federal reporting mechanisms where appropriate. NIH should also consider a tiered reporting framework based on biosafety risk or public health significance that promotes transparency while preserving strong reporting cultures, protecting sensitive information, and minimizing duplicative reporting requirements.

Additionally, rather than requiring publication of institution-specific incident reports and responses, NIH should consider an anonymized reporting model like the Federal Select Agent Program Annual Report Publications by Federal Select Agent Program | Federal Select Agent Program. Aggregated analyses of key data would provide significant value to both the biosafety and research communities while reducing concerns related to privacy, security, institutional reputation, and potential disincentives to self-reporting. Importantly, data are most meaningful when presented with appropriate context. Isolated incident reports may be prone to misinterpretation and do not necessarily reflect actual risk or compliance performance. Deidentified, aggregated reporting would allow stakeholders to identify trends, understand common challenges, and evaluate the effectiveness of corrective actions. Such an approach would modernize the current OSP reporting framework by providing actionable information to biosafety professionals and IBCs.

Near-Miss Reporting and NBDSAC: We support the development of a national biosafety data repository that captures lessons learned from laboratory-acquired infections, biological exposures, seroconversions, containment failures, and other significant biosafety events. Such a resource has the potential to strengthen biosafety programs nationwide.

However, the draft provides limited information regarding the National Biosafety Data and Safety Analysis Center (NBDSAC), including how data will be analyzed, protected, shared, and translated into actionable recommendations. Investigators may be reluctant to participate if the governance, confidentiality protections, expected outputs, and practical value of the system are not clearly defined. Near-miss reporting systems are most effective when focused on organizational learning and continuous improvement rather than public attribution.

Recommendation: NIH should provide additional detail regarding NBDSAC governance, confidentiality protections, data use, expected outputs, and interaction with existing federal reporting systems. NIH should also describe how findings will be communicated back to institutions and how collected data will be translated into practical guidance, benchmarks, and lessons learned that can improve biosafety and IBC programs nationwide.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Name of Organization: Barbara Johnson + Associates, LLC

Type of Organization: Other

Type of Organization - Other: Consulting

Role: Other

Role - Other: Biosafety Professional

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biosafety and biorisk management for biomedical research and advanced therapeutic platforms

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The following clarifications would help ensure the policy's scope is comprehensive and consistently applied:
• Clarify whether oligonucleotides, cells, and toxins are intended to fall within the definition of biological agent.
• Broaden or clarify the definition of toxin, which currently appears limited to peptides and proteins and does not clearly address synthetic toxins.
• Clarify whether mycotoxins fall within the policy's definition of "toxin" and are considered biohazards under the policy.
• Include animal containment level (ACL) laboratories within the definition of laboratory research, particularly because the policy's scope now encompasses gene drive research.
• Add a definition for self-aggregating protein.
• Define "organism" and clarify its boundaries relative to cells, viruses, biological agents, synthetic or minimal-cell systems, multicellular models, animals, and other engineered biological systems, with representative examples and exclusions relevant to biomedical laboratory research.
• Clarify whether a lipid nanoparticle (LNP)-encapsulated ribonucleic acid (RNA) product is independently within scope before cellular uptake and whether oversight is triggered by handling the formulated product, delivery into cells or research animals, the resulting transiently modified cells, or a combination of these circumstances.
• Address non-viral and non-integrating RNA modalities explicitly, including conventional messenger RNA (mRNA), self-amplifying RNA, circular RNA, naked RNA, and RNA delivered by lipid nanoparticles or other non-viral delivery systems.
• Provide phase-specific examples identifying when LNP-RNA research enters and exits policy scope across RNA synthesis or purification, formulation or handling, in vitro cellular exposure, animal administration, and administration to human research participants, and clarify whether Institutional

Biosafety Committee (IBC) oversight attaches to the material, the activity, the modified cell, or the full protocol.
• Provide risk-assessment criteria for these modalities, including delivery efficiency, biodistribution or cell targeting, persistence, replication competence, integration potential, encoded product, dose or scale, route of exposure, and the potential consequences of unintended cellular uptake, so oversight is calibrated to actual biological risk.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: NIH should clarify how synthetic nucleic acid molecules should be evaluated within the Risk Group framework, including whether they should be assigned a Risk Group or evaluated using separate risk-based criteria. NIH should also identify the characteristics or conditions—such as delivery method, persistence, replication or integration potential, encoded product, concentration or scale, and potential for unintended cellular uptake—that warrant additional control measures for synthetic nucleic acid molecules.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Before establishing mechanisms for voluntary compliance, NIH should clarify the policy's applicability to research supported by other federal agencies. The policy should distinguish between institutions subject to the policy because they receive NIH funding and research funded solely by another government agency. NIH should also clarify whether other agencies are expected to adopt or incorporate the policy into their award terms and how the policy interfaces with government-wide or agency-specific biosafety and biosecurity requirements. In addition, NIH should clarify whether and how the policy applies to NIH-supported research conducted outside the United States, including work performed by foreign recipients, research sites, collaborators, contractors, or other foreign components. NIH should address how institutions should comply when policy requirements differ from local laws, national biosafety oversight systems, privacy requirements, public-disclosure obligations, or IBC composition requirements. For institutions participating voluntarily, NIH should establish reporting timelines that allow sufficient time for required legal, confidentiality, and proprietary-information review before detailed incident information is submitted.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: General Comments on the Draft Policy and Templates
• The 24-hour reporting requirement may be difficult to meet because BSOs are not always notified of incidents within that timeframe.
• The policy should clarify what information must be submitted within the initial 24-hour period and whether the requirement applies to all reportable incidents or only those meeting a defined severity threshold.
Incident Reporting Template
• The template should include options for chronic exposures and laboratory-acquired infections (LAIs).
• The incident reporting template should request the amount or concentration of the biohazardous material or organisms involved in the incident.
• The incident narrative should ask whether secondary transmission to another person or animal host occurred outside the laboratory.
Meeting Minutes Template
• The Meeting Time field should include the applicable time zone.

• Align the Meeting Minutes Template with the policy's mandatory IBC membership and quorum requirements. For example, the template describes participation by at least one non-affiliated member as a recommendation, while the policy requires at least two non-affiliated members.
• Clarify how voting members make decisions, including whether approval is based on a majority vote, and add corresponding voting-decision details to the Meeting Minutes Template.

6. Other feedback relevant to this resource: Additional guidance would be beneficial in the following areas:
• Clarify whether institutions are required to appoint an Authorized Organizational Representative (AOR) and specify the qualifications or selection criteria for this role.
• The policy should clarify whether IBC community members must reside within a specified distance of the site served by the IBC.
• The policy should clarify whether a BSO may also serve as the IBC Chair.
• Ad hoc consultants should not fill designated community-member positions on an IBC. Compensating an individual serving in a community-member role could create an actual or perceived conflict of interest.
• Provide instructions or a supporting resource describing how institutions may petition NIH to assign a Risk Group to a new or emerging agent not addressed in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).
• Clarify the NIH office or body to which reportable incidents must be submitted and provide a single, clearly identified reporting pathway.
• Clarify whether theft of biohazardous material is a reportable incident and whether biosecurity incidents are within the scope of the policy.

Additional Request for Clarification:
Section III-C should distinguish voluntary submissions from required incident reports. Incidents involving an environmental release or a laboratory-acquired infection appear to require reporting to NIH and therefore should not be characterized as voluntary submissions.
In Section V-E, present mitigation measures in an order consistent with the recognized hierarchy of controls: elimination or substitution, where feasible; biological containment based on agent or organism design; physical or engineering controls, including facility design and primary barriers; administrative controls, including practices, procedures, and training; and safety equipment and personal protective equipment.
Before implementation, NIH should provide stakeholders an opportunity to review and comment on the next draft of the policy, particularly if substantive revisions are made in response to the current public comment period. An additional review period would help identify implementation challenges and clarify requirements before the policy becomes effective.

Type of Organization: Non-Profit Research Organization

Role: Investigator/Researcher

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious Disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: A large gap in IBC oversight relates to use of RNA and DNA proteins for vaccine development. I highly recommend that clear guidance be provided by NIH to require that institutional IBCs review all protocols for mRNA, DNA, and protein expression of all select agents and Risk Group 3 and 4 agents. Although these materials might not threaten physical safety, they carry inherent biosecurity risks.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): OHSU

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Define the boundary of the policy
The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.
Use internally consistent terminology
The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.
Clarify plant and animal coverage
CSHEMA | Public Comment
The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.
Calibrate toxin and protein scope to meaningful risk
The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins

without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other
self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition.
NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.
Separate scientific definitions from policy applicability
“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs
at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.
Clarify policy application on existing IBC approvals
NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.
As written, “may be contaminated” could be interpreted to include virtually any primary human or animal cells (including any research involving NHP cells or tissues) for which the infectious-agent status of the source has not been comprehensively established.
NIH should define “adventitious agent,” establish a risk-based threshold for determining when contamination is reasonably anticipated, and clarify whether donor screening, testing, source information, or other documentation can establish that primary cells do not fall within this category. The Policy should also clarify its application to commercially obtained cells, repository specimens, patient-derived cells, and primary animal cells and provide examples of included and excluded materials. A merely theoretical possibility of contamination should not independently trigger IBC oversight; the definition should be tied to a known or reasonably anticipated potential hazard to human health. Clear criteria are necessary to avoid additional administrative burden by unnecessarily expanding IBC oversight beyond research presenting a meaningful biosafety risk.

The Policy does not provide sufficiently objective criteria for determining when a cell line qualifies as well-characterized, creating the potential for inconsistent interpretations among investigators, biosafety professionals, and IBCs. NIH should specify what level of information regarding identity, provenance, biological characteristics, and adventitious-agent testing is necessary; whether established commercially available or widely used cell lines may be presumed to satisfy the definition; and how primary, immortalized, genetically modified, and patient-derived cells should be treated. NIH should also provide examples of included and excluded cell lines. Because this determination may affect the scope and level of institutional oversight, a clear, risk-based definition is necessary to ensure consistent implementation and avoid additional administrative burden by unnecessary review of research that does not present a meaningful biosafety risk.

IBC review is appropriate for the review of research involving prions or biospecimens identified to be from a person or animal known to have a prion-based disease. However, the term self-aggregating is not

sufficiently defined to permit institutions or investigators to determine consistently if every protein that happens to aggregate or contributes to an aggregation-associated human disease, such as ALS, is also covered.

Protein aggregation alone does not necessarily establish a meaningful biosafety hazard. NIH should clarify whether "other self-aggregating proteins" is intended to encompass proteins with prion-like, seeding, propagation, transmissibility, pathogenic, or other specified hazard characteristics rather than any protein capable of aggregation. The definition should identify objective criteria and provide examples of both covered and excluded materials.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported "in full" at the

next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway

is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report

to the IBC, with records retained for audit. The full committee's role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently

routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Continued utility of Risk Groups: Retain Risk Groups as a starting point
Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.
Distinguish genetic engineering from other forms of change
The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.
Avoid rigid containment rules that conflict with risk assessment
A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment
and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language
that could apply to any construct containing any listed segment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Align accountability with authority
The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.
Provide procedures for managing overlapping federal policies
The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.
Assign institutional responsibilities appropriately
The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.
Clarify governance requirements
A member who is recused because of a conflict should not count toward the quorum needed for action on
that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations
for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have

difficulty recruiting unaffiliated members.
Recalibrate public posting
Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.
Define redaction and timing rules
If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions
necessary for the protection of proprietary and security-sensitive information. The NIH must also establish
a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.
Map retention requirements to record types
The final policy should include a record-retention table for protocols, risk assessments, delegated reviews,
training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and
any superseding award or legal requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It is recommended that NIH revise the approach to public posting of incidents so that detailed incident reports are submitted to NIH but are not routinely required to be posted publicly in their entirety. Alternatively, NIH could provide a template for public posting of standardized, de-identified high level summary information of incidents that might include root-cause categories and corrective actions. NIH could separately require disclosure of additional information when a particular incident presents a compelling public health or safety interest.
This approach balances transparency objectives with the equally important need to preserve a just, non-punitive reporting culture in which researchers and staff are encouraged to report incidents, near misses, and potential safety concerns promptly and completely. It also provides protections for researchers that are increasingly threatened or harassed due to the tools or subject matter of their research.
Importantly, NIH would receive the information necessary to evaluate significant incidents, institutional responses, and compliance. The distinction would therefore be between information necessary for regulatory oversight and information necessary for public transparency, rather than assuming that the same level of detail is needed for both purposes.

6. Other feedback relevant to this resource: The timeline for institutional implementation and compliance with the revised policy should be at least a year after the publishing of the final rule instead of 6 months.
A six-month implementation period is insufficient given the breadth, complexity, and institutional

impact. Revising electronic systems to accommodate the new regulations is a significant challenge that will likely prevent many institutions' ability to meet this timeline. Additionally, updating policies and procedures and ensuring that researchers have the training they need to understand the new requirements, including newly covered areas of research, will require additional time. The time required to identify newly covered research is one reason why it is critical for entities to be held to realistic and achievable implementation timelines.

NIH should provide a detailed description of the required elements of an institutional assurance and publish accompanying implementation guidance before policy adoption, including model assurance language, implementation templates, and sufficient lead time for institutions to develop. Administrative burden should be kept in mind in considering required elements.

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Currently, sections III-E-3-a and III-F of the NIH Guidelines include specific materials involving recombinant or synthetic nucleic acids as well as transgenic rodents that are exempt from the Guidelines. In the new policy, it sounds like these projects would now fall under section IV-3 and would now need an IBC review. Is this the correct interpretation? If so, I would suggest that these low risk projects continue to be exempt in the new policy since they pose little risk to the people working with them. There have been no laboratory acquired infections documented from exposures to materials or transgenic animals listed as exempt in the current NIH Guidelines.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): One of the most positive aspects of the new NIH Biosafety Policy is the alignment with the BMBL. The focus on a thorough risk assessment in order to assign a containment level for projects is another welcome addition in the new policy.

3. Continued utility of Risk Groups: Section IV-1 in the draft policy requires both NIH and IBC approval and lists the following as falling under this category:
Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL.

In the draft policy, chimera viruses are defined as "novel agents", which would put them in the highest risk category. Chimera viruses most commonly consist of a non-hazardous virus with different pieces of a hazardous virus attached to it, in order to test for antibody production. Will every chimera moving forward need to be reviewed by both the NIH and IBC? Or will common chimeras be able to be included in a section IV-2 review (ex. VSV based chimeras)? Could NIH develop a definition of chimera virus that more clearly delineates the level of risk and review?

The policy states that un-modified RG1 organisms are exempt from the policy. Is this defined as RG1 listed in the BMBL, meaning that organisms classified as RG1 in other publications would still fall under this policy if they are not specifically listed as RG1 in the BMBL? As written, it seems as though the policy

treats non-hazardous gut microbiota, such as found in in over the counter pro-biotic supplements, as higher risk organisms because they are not specifically listed in the BMBL. Could NIH clarify how non-hazardous bacteria should be categorized if the species does not have an affirmative RG1 classification? Otherwise, there could be an unintended consequence where NIH program staff may experience increased administrative burdens of updating a high volume of RG1 classifications for research to proceed.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: There are concerns of unintended consequences regarding the public posting of biohazard incident reports. Currently, the incident reporting and review process receives significant buy in and participation from investigators as it is seen as a positive process to learn from incidents and improve safety systems and processes. Because of this positive attitude regarding incident investigations, PIs readily report biosafety incidents. I am concerned that posting the incident reports on a public website and requiring the PI name and funding sources could discourage how forthcoming PIs and their laboratory personnel are about reporting incidents. The PI name and funding information does not add to the incident analysis, which helps determine the cause of the incident and helps to prevent similar incidents from occurring in the future. Additionally, the PI name and funding information is not necessary for demonstrating public transparency to the local community. Incident reports could be publicly posted without this information to demonstrate transparency.

A better definition of a “significant” incident is needed to classify incidents that occur.

6. Other feedback relevant to this resource: Extending the implementation timeline from 6 months to 12 months for newly in scope research projects would help smooth out the administrative labor needs for both the initial review processes and re-review every three years. Grandfathering existing IBC approvals for projects would also help mitigate administrative burdens and then have those projects comply with the new requirements for the next review cycle after the policy is finalized.

Submission Portal:	Submitted via NIH OSP Electronic Comment Portal
Subject / Notice:	Formal Public Comments and Recommendations on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice Number: NOT-OD-26-112)

ABSA International, the Association for Biosafety and Biosecurity, is a nonprofit professional association representing biosafety and biosecurity professionals in the United States and internationally. Our membership spans academic and research institutions, government laboratories, biotechnology companies, healthcare organizations, public health agencies, and consulting practices. Members bring scientific, technical, operational, and regulatory expertise across diverse biological research and laboratory settings.

ABSA's comments reflect the practical experience of professionals responsible for translating biosafety policy into daily practice. Our members conduct risk assessments, support Institutional Biosafety Committees (IBCs), develop training and containment practices, investigate incidents, and advise institutions on compliance. They understand how policy requirements affect laboratory safety, reporting culture, institutional resources, and the conduct of research.

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public

confidence in NIH-supported science. ABSA supports NIH's efforts to strengthen biosafety oversight. We offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

***Topic to Address**: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:

    a. the nature and stability of the genomic modification;

    b. whether the modification is heritable and the potential for transmission through breeding;

    c. effects on animal health, phenotype, host range, susceptibility, or disease;

    d. potential entry into breeding or food-production systems;

    e. potential environmental release or interaction with non-research animal populations;

    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and

    g. applicable federal, state, or other regulatory oversight.

2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

  Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

ABSA International believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, ABSA International requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, ABSA International welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. ABSA International does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. ABSA International recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, ABSA International recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with ABSA's earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. ABSA International recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, ABSA International kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. ABSA International encourages NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While ABSA supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: ABSA recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Reference basis: Draft NIH Biosafety Policy, Section V-E; NOT-OD-26-112 implementation-resource statement. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7, and Appendix G-II-C-5.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Remove mandatory review of routine minimal-risk activities
Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definition of "biological agent" is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other
self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition.
NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: The proposed definition of genetic modification includes passaging, reassortment, and chemical or
radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse,
ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment
and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language
that could apply to any construct containing any listed segment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The draft says research also under another federal agency's regulation or purview "may proceed under
the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Public posting of detailed IBC minutes and all incident reports could expose proprietary research details,
personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft should define “incident,” “basic first aid,” “agent-specific treatment,” “potential exposure,” “compliance violation,” and “minor spill.” The policy should clarify whether precautionary post exposure prophylactic treatment is considered “agent-specific treatment”. It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Role - Other: Biosafety Officer - why isn't this an option for a draft on a BIOSAFETY Policy?

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): biomedical research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Define the boundary of the policy: The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.
2. Use internally consistent terminology: The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. NIH should also define GDMO and consistently use the term throughout the policy.
3. Clarify plant and animal coverage: The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.
4. Calibrate toxin and protein scope to meaningful risk: The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.
5. Separate scientific definitions from policy applicability: “Biomedical research” should be defined by

the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.
6. Clarify policy application on existing IBC approvals: NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 1. Create a clear precedence rule: Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.
2. Ensure delegated review actually streamlines oversight: Delegated review is a welcome modernization, but requiring every approval to be reported "in full" at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee's role after delegated approval should also be defined.
3. Remove mandatory review of routine minimal-risk activities: Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not require IBC review when they present minimal biosafety risk. Requiring this review seriously undermines the credibility of this policy.
4. Limit federal review to clearly defined circumstances: Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.
5. Make NIH precedents reusable: NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Continued utility of Risk Groups: 1. The four groups address the risk to both the laboratory worker and the community and correlate with, but do not equate to, Biosafety Levels (p12 - BMBL 6th Ed).: Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

2. Distinguish genetic engineering from other forms of change: The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.
3. Avoid rigid containment rules that conflict with risk assessment: A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): 1. Align accountability with authority: The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.
2. Provide procedures for managing overlapping federal policies: The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required and what records the IBC is required to receive, review, or retain when concurrent IBC is not required.
3. Assign institutional responsibilities appropriately: The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures. The policy should define the role of BSO and the requirement for being a BSO.
4. Clarify governance requirements: NIH should specify the expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.
5. Recalibrate public posting: Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.
6. Define redaction and timing rules: If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response."

Institutions should not be held to a posting deadline that depends on an open-ended federal review.
7. Map retention requirements to record types: The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1. Resolve overlapping and undefined categories
The draft should define “incident,” “basic first aid,” “agent-specific treatment,” “potential exposure,” “compliance violation,” and “minor spill.” The policy should clarify whether precautionary post exposure prophylactic treatment is considered “agent-specific treatment”. It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.
2. Keep reporting of lower-risk events within local IBC purview: NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.
3. Use aggregate public reporting
The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency.

6. Other feedback relevant to this resource: 1. Provide a minimum 36-month phased implementation period: The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 36 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.
2. Pilot the policy and templates: NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.
3. Develop implementation resources: Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

4. Address the cost of compliance: The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.
5. Allow flexible institutional models: The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

6. Other feedback relevant to this resource: the following should be included in the final text or in binding implementation guidance published with the final text:

● Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
● Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
● Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
● Define when a prior NIH containment determination may be used by another institution without a new
petition.
● Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
● Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
● Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events,

minor spills, and compliance violations that do not present a meaningful safety risk.
● Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

230. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Coverage and decision rules
The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration: Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration: Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Policy reference: Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration: Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration: Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident thresholds: investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration: Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration: Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration: Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

6. Other feedback relevant to this resource: (1) Public disclosure and record retention:
The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public

disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

(2) As biosafety compliance faces increasing scrutiny, it would be beneficial for the institution to provide financial support for these types of biosafety oversight activities.

(3) Assurance submission approval and renewal
A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration: Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration: Specify and define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration: Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

231. University of Texas Medical Branch

I am responding: On behalf of myself

Name:

Name of Organization: University of Texas Medical Branch

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am an Associate Professor at the University of Texas Medical Branch. I have worked in the field of infectious diseases, particularly on important human pathogens, including viruses requiring biosafety containment levels ranging from BSL-1 to BSL-3. I support replacing the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines) with a risk-based biosafety oversight framework. I offer these comments to help the NIH develop clear, proportionate, and practical requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The significant concerns raised in these comments, as well as by the broader scientific community, demonstrate that the draft Policy cannot be implemented in its current form. We respectfully request that the NIH revise the Policy and publish additional drafts for public comment before issuing a final version. While we fully support the NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy could hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and undermine the collaborative relationship among researchers, regulators, and the biosafety compliance community.

1) The stated intention of this policy proposal is to expand the scope of the NIH Guidelines while removing red tape for low-risk research. The goal of removing red tape for low-risk research within this Policy has not succeeded. The Draft Policy includes within its scope multiple categories of research that are currently Exempt in the NIH Guidelines. For example, research with certain transgenic rodents and certain recombinant work with non-pathogenic E. coli; the NIH Director has already determined that these experiments are of such low risk that they were actively designated as Exempt, yet this Policy considers them of high enough risk to require IBC approval. The Policy does not provide reasoning for this change in the risk assessment.

2) A meaningful administrative burden with the NIH Guidelines is the pathway through which NIH OSP will assign a biocontainment level for research with an agent that does not have an assigned RG within

Appendix B. This issue could be less burdensome if NIH OSP had been granted authority within the Guidelines to assign a risk group to agents that do not have risk groups.
3) The current approval pathway is limited to the specific PI at a specific entity. Therefore, other PIs at the same entity are similarly required to obtain a biocontainment level from NIH OSP for the same agent.
4) The Scope of the Policy states "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." This statement must be clarified. We appreciate that the Policy seeks to avoid duplicative oversight from multiple federal agencies. However, the statement itself is unclear regarding the oversight, approvals, and clearances that are mentioned.
a. If a researcher is registered to work with wildtype Nipah virus (RG4, therefore falling under Section IV-2) with the Federal Select Agent Program (FSAP), do they not need to obtain IBC approval for the same work?
b. If a researcher is registered to generate chimeras of paramyxoviruses within a Nipah virus backbone (a novel agent by the current definition, therefore falling under Section IV-1) with FSAP, do they need to obtain NIH and IBC approval for the same work?
c. If an incident occurs in a BSL3 or BSL4 that involves a Select Agent for which the researcher is registered with FSAP, does the incident get reported to NIH and posted on a public facing website?

5) Effective Date. The Policy states that the effective date will be 6 months from publication of the final Policy. This is a very short timeline to implement a Policy with such significant expansions in scope. Implementation of this Policy will require that IBCs ask for more resources from their institutions, obtain those resources, communicate with stakeholders, develop new training, implement training for IBC members and researchers, obtain new software or update software, and make significant choices in how to implement each part of the Policy. Six months is not nearly sufficient, and all entities will struggle. This is further complicated by the need to provide a written Biosafety Assurance that has been approved by NIH in order to perform any research after the effective date. Will NIH have the FTEs to review and approve hundreds of Biosafety Assurances that will be submitted within that effective date?
6) The Policy uses terms and words but does not define them. The failure to define these words will lead to ambiguity in the interpretation and implementation of the Policy, leading to unintentional noncompliance. Further, some of these words did not have definitions in the NIH Guidelines and therefore this is a good opportunity to rectify this issue. These include:
a. Adventitious agent, organism, transgenic, GDMO, incident, release, potential risk to human health, peptide, shedding. Organism is inconsistently used within the Policy and is not an easily defined word. Replace "organism" with more appropriate and easily definable terms throughout the Policy. Specify bacteria, fungi, archaea, protists, viruses, or animals as needed. If there is a concern about a biological agent that doesn't fall within those terms, be clear about that (e.g., a biological agent created through synthetic biology that cannot be readily categorized).
b. The Policy omits a review workflow for biological agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL yet cannot reasonably fall within the definition of "emerging, novel, or zoonotic agents". This is a crippling issue for agents that are currently handled at BSL1 or BSL2, though is also an issue for agents handled at BSL3 and BSL4. Theoretically, these could fall within Section IV-1 (research that requires NIH and IBC approval before initiation). However, the administrative burden on NIH to adequately review this work in a timely manner would be significant (even ignoring the administrative burden on researchers and IBCs to review

this work). Additionally, much of this research cannot reasonably fall under the category of “higher risk research”, when even research involving RG3 or RG4 wild-type biological agents requires only IBC review in the Policy.
For example, human metapneumovirus, non-polio enteroviruses, human parainfluenza virus 5 (Orthorubulavirus mammalis), and Sendai virus (Respirovirus muris) are not emerging, novel, or zoonotic agents. Yet they lack a risk group in the NIH Guidelines and are not mentioned in the BMBL. Will NIH review be required for research with these agents for every entity and researcher that falls in scope of the Policy? If so, how many FTEs will NIH be hiring to accomplish timely reviews?
How will human or animal microbiota be treated in this review workflow? Will research with every member of Bacteroides, Bifidobacterium, Akkermansia, Ruminococcus, Prevotella, and Anaerococcus require NIH review? If so, will a researcher even be able to collect a human or animal sample without being in noncompliance with the Policy?
c. The Policy does not define who has the authority to designate the risk group of an agent. This is of particular importance with RG1 biological agents, since the Policy explicitly states that wild-type RG1 biological agents are outside the scope of the Policy. If the local IBC will have the authority to designate the risk group of an agent, that needs to be stated in the Policy. If the NIH will have the authority to designate the risk group of an agent, that needs to be stated in the Policy. In addition, NIH must publish and regularly update the list of biological agents that it designates at different RGs.

7) Responsibilities of the Institution (Section III-A), related to records retention. The Policy states “The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states “the recipient and subrecipient must retain all Federal award records for three years from the date of submission of their final financial report.” (emphasis added). The Policy assumes that all IBC records are for projects that are federally funded. The Policy has failed to consider projects that are not federally funded and therefore will never submit a final financial report. As written, such IBC records may never be disposed of, which is either an oversight or regulatory overreach. This language must be changed to account for IBC records related to non-federally funded projects.

8) The Policy states “Approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required.” The Policy fails to describe how biosafety or biosecurity is increased by limiting research approvals to three years. Researchers continue projects over years and decades, and these projects rarely include changes that significantly increase the risk assessment. Requiring a specific time frame for approvals is overly burdensome and regulatory overreach. Requiring such a short approval time will greatly increase the administrative burden of the IBC and the researcher for little to no increase in biosafety. We recommend that this statement be removed from the Policy. If the statement cannot be removed from the Policy, we recommend that the Policy explicitly permit grandfathering of previously approved IBC protocols that have approval periods of greater than three years.

9) Responsibilities of the IBC (Section III-B), incident reporting. The Policy does not define “incident” or “release”. We recommend the following definitions:
Incident: A confirmed theft, loss, or release (such as an occupational exposure or a release outside the

defined biocontainment barriers) of biological material under the scope of the Policy.
Release (Loss of containment or occupational exposure): Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
The Policy does not define "improper disposition" and throughout this section relies on ambiguous phrases such as "any incident", "loss of containment", "significant problems", and "minor spills … generally do not need to be reported". Terms like "first aid" and "medical treatment" should be aligned explicitly with OSHA standards.

10) Responsibilities of the NIH (Section III-D)
The Policy does not state which person or office within NIH will be responsible for these items. In comparison, the NIH Guidelines clearly delineated the responsibilities of the NIH Director and the responsibilities of the NIH Office of Science Policy. Entities can reasonably expect that the response times for the NIH Director and for NIH OSP will be significantly different. Further, NIH OSP is staffed with many subject matter experts, while the NIH Director can never be an SME for every aspect of biomedical science. Therefore, the Policy must clearly state who will be responsible for these duties. We recommend that the Policy clearly state which person or office is responsible for the duties described in this section.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 1) In general, the tiered oversight is appreciated. The IACUC-style review that specifically permits delegate approval will be a helpful decrease to time commitments from the full IBC for review of lower risk research. The Policy has replaced two previous categories of review, those requiring NIH Director approval (III-A) and those requiring NIH OSP approval (III-B), with a singular category that requires NIH approval. The Policy does not describe which person or office within NIH will be performing the review and approval of research within Section IV-1. This must be clearly stated in the Policy within the Responsibilities of NIH (III-D).

2) General Definitions: Emerging agent or organism. The Policy does not state who determines that an agent is an emerging agent. Does the local IBC decide what qualifies as an emerging agent? If not the local IBC, we recommend that NIH develop rapid dissemination notices that are sent to all entities identify emerging agents so that entities can avoid noncompliance.
The Policy does not describe how an agent or organism goes from being an emerging agent to a non-emerging agent. Will an agent be "emerging" until the first time NIH has reviewed it under Section IV-1? Until it has been assigned a risk group? Until it has appeared in the next edition of the BMBL? Does the definition of an emerging agent include a well characterized agent that exhibits a change in pathogenicity or transmission? If this Policy existed at the time, would the recent outbreaks of Zika virus, mpox virus, and Andes virus qualify as "emerging"? Would the label of emerging apply to the agent, or merely to the specific strain of the biological agent? If considered now (October 2026), which agents would qualify as "emerging"? Highly pathogenic avian influenza virus H5N1? SARS-CoV-2?

3) General Definitions: Genetic Modification. This definition is so expansive that it causes internal contradictions within the Policy. The definition uses the undefined word "organisms", which is unhelpful. As written, this causes the Policy to confusingly regulate research conducted with genetically modified organisms (Section IV-2) differently from transgenic organisms (Section IV-3) but does not define the difference between the two. Replace the word organism with the biological agent(s) that are intended to

be within scope of the Policy.
Can be transcribed or translated: as written, this will include expression from an RNA vaccine that is administered to an animal or transfected into a cell line. The Policy does not describe how including this as a genetic modification addresses a biosafety concern. The introduction … of stable alterations into the genome by passaging, reassortment, chemical or radiological means: as written, the definition includes unintentional alterations into the genome, such that researchers will become noncompliant with the Policy almost immediately.
Passaging any virus in tissue culture will result in unintentional alterations into the genome. Cancer research includes work with antineoplastic drugs that would fall within scope of this definition. We recommend that this definition be re-written to be limited to intentional stable modifications.

4) General Definitions: Toxin. The definition of toxin could be greatly improved. For example, ISO35001 uses “substance, produced by plants, animals, protists, fungi, bacteria, or viruses, which in small or moderate amounts produces an adverse effect in humans, animals, or plants. This includes substances and materials, natural or as a result of biotechnology, that may contain toxins, any poisonous substance or any poisonous isomer, homologue, or derivative of such a substance.” The definition should not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (e.g., sensitizers).
Later in the Policy, when defining the Category of research, would be the appropriate time to limit the scope of which toxins fall under the Policy (e.g., Research with protein or peptide toxins not on the Select Agent list and with an LD50 of less than 100 micrograms per kg body weight.)

5) Section IV-1 (Research that Requires NIH and IBC Approval Before Initiation): Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL.
Emerging and zoonotic agents: For those whose research focuses on the identification of new biological agents, the Policy offers no regulatory path to work with these agents. Once identified as an emerging or zoonotic agent with no risk group or biosafety level recommended in the BMBL, the research must be approved by NIH. However, without the ability to work with the agent, the researcher cannot generate the data required for NIH to conduct the risk assessment. Without the ability to perform this research, US researchers will stop performing this work. It will then fall to international researchers to spearhead this work, leaving US researchers lagging behind. We recommend that a clear approval pathway is described in the Policy to allow researchers to generate the data required for a risk assessment. This would best be performed by the local IBC.

6) Novel agents: The definition of novel agents includes chimeras. Many researchers generate chimeras (especially within a family of viruses) to study the basic biology of these agents; in these cases, the representative family member or the parental agents often already have risk groups assigned or biosafety levels recommended. Research with such biological agents does not qualify as “higher risk research” requiring NIH approval; indeed, these experiments currently fall within Section III-D of the NIH Guidelines, clearly demonstrating that for decades NIH has determined that the work can be reviewed by the local IBC and does not require NIH approval. We recommend that research involving chimeric agents generated within the same family (for viruses) or the same genus (for bacteria or fungi), may be reviewed by the IBC. We recommend that research involving chimeric agents where the natural sources

have risk groups assigned and/or biosafety levels recommended, may be reviewed by the IBC.

7) Section IV-2 (Research That Requires IBC Review and Approval Before Initiation). This section states "For initial submissions of research within the scope of the policy, and not otherwise specified in other sections, review and approval must be obtained from the IBC before initiation." Since the Policy includes a regulatory catch-all ("not otherwise specified in other sections"), the Policy must include a section that clearly delineates research that is outside the scope of the Policy. Institutions cannot rely on one-off notes to define research that is outside the scope (e.g., "[Note: Experiments involving RG1 wild-type biological agents are not subject to this Policy]"). Without clear delineation, entities will vary widely between unintentional noncompliance and overly requiring IBC review and approval for work that is outside the scope of the policy.

8) Section IV-2: Research involving RG3 or RG4 wild-type biological agents. We have no objection to including RG3 and RG4 biological agents within scope of the Policy, as our institution already requires that work with these agents be approved by the local IBC.
9) Section IV-2: Research involving genetically modified cells, viruses, or organisms, other than plants (e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs). Policy must be well written and clear; this category is a clear example of policy that is not well written. It is misplaced within the tiers of review; contains terms that are either not defined or badly defined; and conflicts with other categories of research within the Policy. Entities will be uncertain how to comply with this category, leading to chilling effects on the research community, additional administrative burden, and unintentional failures to comply with the Policy. This category is misplaced within the tiers of review. Research with genetically modified cells should be at most within Section IV-3 (delegate review), if not Exempted completely.
The NIH Guidelines has included an exemption for recombinant DNA molecules containing less than one-half of any eukaryotic viral genome that are propagated and maintained in tissue culture at least since the Federal Register Notice in 1994 (Effective June 24, 1994, Published in Federal Register, July 5, 1994 (59 FR 34472)). The NIH Director has therefore determined that such experiments do not present a significant risk to health or the environment. The Policy does not describe how the inclusion of such research in the Policy will increase biosafety and biosecurity. In addition, while a single researcher registering for this work would not be a significant burden, the total number of registrations will constitute a significant collective administrative burden on the IBC and researchers that is not commensurate with the very low biosafety risk.
10) Genetic modification of cells is of very low biosafety risk (barring some introduction of nucleic acids from certain biological agents, like RG3 or RG4 agents, or that will generate toxins). Such work should be exempt from the Policy. Genetic modification is defined by the Policy, but in such an expansive way that that it is prohibitive to research. As an example: as written, the Policy no longer considers administration of recombinant nucleic acids (e.g., RNA vaccines) in humans to be within scope, compared to the NIH Guidelines, where it is within scope (Section III-C-1). However, the Policy includes "genetic modification" of cells and organisms, which as defined includes introduction of nucleic acid molecules that can be transcribed or translated (e.g., RNA vaccines). The Policy does not describe how it has conducted a risk assessment in which deliberate administration of an RNA vaccine into a human is not within scope, yet transfection of the RNA vaccine into cell culture or administration into an animal is within scope and requires IBC approval.

11) Organism is not defined by the Policy, which makes this category frustrating to understand and will lead to significant unintentional noncompliance. As written, this category appears to include animals, despite the category of “transgenic organisms at BSL1/ABSL1” listed in Section IV-3. The word organisms must be defined by the policy or replaced in this section.

12) Vector is not defined by the Policy, which will lead to significant unintentional noncompliance. Is the intention here to regulate viral vectors (e.g., lentiviral), arthropod disease vectors (e.g., mosquitoes), or something else?

13) Gene drive modified biological agents is not defined and is a confusing term. Biological agents in the Policy are defined as bacteria, viruses, fungi, or parasites, yet gene drive technology requires Mendelian genetics, such that this would be limited to fungi or parasites. The subsequent use of GDMO in this category suggests that gene drive modified biological agents are different from GDMOs, but this delineation is not clear.

14) GDMOs are not defined in the Policy. We recommend that this category be removed from the Policy or extensively re-written, as described below. The definition for Genetic Modification should be re-written to be limited to stable alterations in the genome. Definitions for organism, vector, GDMO and gene drive modified biological agents must be added to the Policy (or removed).
Research with genetically modified risk group 3 and 4 biological agents should be approved by the IBC.
Research with genetically modified risk group 2 biological agents should be approved by IBC delegate.
Research with GMDOs should be approved by the IBC.
Review and approval of research with genetically modified cells should be dependent on the modification, some of which may fall within IBC approval, delegate approval, or be completely exempt from the Policy.
15) Section IV-2: Research with primary cells that may be contaminated by adventitious agents. As noted above, the Policy does not define adventitious agents. Therefore, entities will be uncertain how to comply with this regulation and will rapidly be in noncompliance. If the intention of the Policy is to regulate primary cells that may be contaminated by bloodborne pathogens, there is a significant risk assessment issue: research with samples that may be contaminated requires full IBC review, yet research with known RG2 biological agents requires delegate review.
For clinical samples suspected to contain higher consequence pathogens (Brucella, Herpes B, M. tuberculosis, etc.), the BMBL states that BSL2 practices, containment equipment, and facilities are recommended for routine handing of clinical specimens of human or animal origin. The Policy should harmonize the level of review required for these samples: at most they should require delegate review.
We recommend that this section be removed from the Policy. If it must be regulated by the Policy, “adventitious agent” must be clearly defined within the Policy. If it must be regulated by this Policy, we recommend that this work not require IBC or delegate approval as long as the entity is complying with OSHA Bloodborne Pathogens Standard or its equivalent. If it must be regulated by this Policy, we recommend that it should not fall under the category of requiring IBC approval and should at most be in Section IV-3, where delegated review is permitted.
If the intention of the Policy is to regulate primary cells that may be contaminated by any unknown biohazard (for example field samples), that is not clear and needs to be much more clearly defined.

16) Section IV-2: Research with wild type or genetically modified RG2 biological agents for which lower containment is requested, or research with wild type or genetically modified RG3 or RG4 biological agents that NIH has previously approved to be conducted at lower containment.

The Policy implies that there will be a workflow of (1) an entity submits an initial request for NIH to lower containment involving wild type or genetically modified RG3 or RG4 biological agents, (2) NIH will make a determination on whether that lower containment is appropriate, (3) NIH will be responsible for publishing approved determinations of appropriate lower containment for these agents, (4) subsequently, research involving these agents may be approved by the IBC alone (without NIH approval). This workflow should be expressly stated in the Policy to minimize confusion. This includes a clear statement that once NIH has made the determination and published it, other entities will not be required to obtain NIH approval. This would be in contrast to the current system, where approvals are provided only to the single PI at the single institution.
The method by which NIH will publish these determinations should be described, including the minimum time frame (determinations will be published within 1 month, within 6 months, annually, etc.).

17) The Policy should be clear on how much information will be released together with these determinations. Specifically, whether the information include security sensitive information or unpublished data.

18) Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): Research involving RG2 wild type biological agents.
We have no objection to including RG2 biological agents within scope of the Policy, as our institution already requires that work with these agents be approved by the local IBC. However, we are very concerned that there is not a thorough list of RG2 biological agents and/or biological agents that are recommended to be worked with at BSL2. Will all agents not listed in the BMBL require review by NIH? We recommend that the NIH make a detailed, publicly available list of RG1, RG2, RG3, and RG4 biological agents to supplement the BMBL. Appendix B of the NIH Guidelines should serve as the backbone of this document.
The inclusion of RG1 organisms is an important part of such a list, since they are outside the scope of the Policy, yet the Policy specifically states that “absence of agent specification in the list of RG2-RG4 does not imply automatic or implicit classification as RG1”. If other federal entities (USDA, CDC, etc.) participated in creating a central list that also includes plant or agricultural considerations, that would be greatly appreciated. If NIH cannot make a detailed publicly available list of RG1, RG2, RG3, and RG4 biological agents to supplement the BMBL, we recommend that the Policy clearly states that the local IBC has the authority to perform the risk assessment and make that determination.

19) Section IV-3: Research conducted with transgenic organisms at BSL-1/ABSL-1.
The purchase and transfer of transgenic rodents requiring BL1 containment is exempt in the NIH Guidelines (Appendix C-VII). Further, the generation of certain BL1 transgenic rodents is exempt in the NIH Guidelines (Appendix C-VIII). In 2011, NIH deemed that “… these breeding experiments do not pose an appreciable risk to human health or to the environment. In addition, while registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective

administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk." (January 19, 2011, Federal Register, January 19, 2011 (76 FR 3150)). As documented in NIH guidance documents, the subsequent use of these BL1 transgenic rodents is also exempt (https://osp.od.nih.gov/wp-content/uploads/2022/11/Animal_Activities_Table.pdf). The same risk assessment should apply today, and the Policy should not require that work with transgenic rodents that can be housed at ABSL1 be approved by the IBC.

As noted previously, there is no definition of organism in the Policy. Therefore, we recommend changing this to animal in this section. We understand that research with some transgenic animals may not have had the time to demonstrate the same safety track record as transgenic rodents and therefore should continue to require IBC approval before that research is conducted. We would recommend that NIH seriously consider that transgenic fruit flies or zebrafish could be exempted due to their safety track record. We recommend that this be re-written as: Research conducted with transgenic animals, other than transgenic rodents, fruit flies, and zebrafish that may be housed at minimum BSL-1/ABSL-1/ACL-1.

20) Section IV-3: Research with genetically modified RG1 biological agents.
Certain research not requiring NIH-OSP approval and not involving DNA from RG3, RG4, or restricted organisms with specific risk group 1 biological agents is exempt in the NIH Guidelines (Appendices C-II, C-III, C-IV, and C-V), having been determined by the NIH Director to not present a significant risk to health or the environment. The Category here (research with genetically modified RG1 biological agents) is in contradiction to this determination and would require that work that was previously exempt now requires IBC approval. The Policy has not described why this risk assessment has changed.
We recommend that this category be removed from the Policy. Additionally, a list of RG1 biological agents is not available. If any part of the Policy references RG1 biological agents, including as work that is outside the scope of the Policy, a list should be developed and published by NIH as part of this Policy, or the local IBC should be granted the authority to designate agents as RG1.

21) Section IV-3: Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes.
This category of research is of low biosafety and biosecurity risk. The Policy fails to describe how regulating this research will increase biosafety or biosecurity. This category will set entities up for failure, with no clear benefits to our biosafety programs. Registering research with plasmids will lead to extensive unintentional noncompliance. Researchers generate plasmids regularly and the requirement to obtain approval for these plasmids from the IBC will be a severe bottleneck.
The Policy fails to describe the extent of what is required to be registered as part of this section. Only the plasmid backbone? The backbone with every gene the researcher will insert? The backbone with every gene and every mutation of that gene?
The administrative burden for researchers and the IBC will be significant and is not balanced by any increase in biological safety. We recommend that this category be removed from the Policy.

22) Section IV-3: Research with well-characterized cell lines.
Registering work with well characterized cell lines will lead to extensive unintentional noncompliance. The administrative burden will be crippling for researchers and IBCs. This category will set entities up for failure, with no clear benefits to our biosafety programs. The Policy fails to describe the biosafety

concern that is being addressed by this category of research. The Policy does not describe the extent of what is required to be registered. It is solely that a researcher is performing work with cell lines? Is it every cell line that the researcher will work with? May the entire ATCC catalogue be approved? We recommend that this category be removed from the Policy.

23) Section IV-3: Research with biological toxin proteins not on the Select Agent list.
Under the definition within the Policy, this category includes food allergens, animal allergens, even FBS, since they can cause harm to humans, yet there is no indication that this is intended. The milk that a researcher is using as part of a Western blot falls within scope of this category.
There is a conflict between the wording in this Section (research with biological toxin proteins) and the definition in the Policy for Toxin (a protein or peptide produced …). This conflict makes it difficult to understand what is within the scope of the category.
This category of research must include a clear definition of which toxins are within scope, including an LD50, or entities will be inadvertently noncompliant.
At our institution, work with toxins are already regulated by our Chemical Safety Committee, which provides regulatory oversight of this work. Additional oversight by the IBC will not increase safety and will instead increase regulatory burden.
We recommend that this category be removed from the Policy. If this category is not removed, we recommend that this be re-written as: Research with biological toxin proteins with an LD50 in vertebrates of <100 micrograms per kilograms of body weight.
Additionally, a list of toxins currently classified under this category must be provided in the Policy. The list of toxin molecules classified as to LD50 that is currently available from NIH OSP under the NIH Guidelines (Appendix F-1) should serve as the backbone of this list.

3. Continued utility of Risk Groups: 1) Risk Groups as Hazard Characterizations vs. Site-Specific Risk Assessment .
Risk Groups remain valuable tools for initial hazard communication and agent characterization, but they should not independently dictate containment or review levels. The final policy must preserve site-specific and experiment-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations. This aligns with Section V-E of the draft policy, which explicitly acknowledges that Risk Groups and Biosafety Levels are related but non-equivalent concepts.
2) Critique of Mandatory IBC Petitions for Emerging, Novel, or Unlisted Agents (Section III-B) .
The 'IBC Functions' section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents 'for which the RG classification or containment level is not available in the BMBL,' prohibiting IBC approval until authorized by NIH and any other applicable entities.
3) Terminology Inconsistency: The draft text treats 'RG classification' and 'containment level' as alternative terms residing in the BMBL. However, Section V-E correctly states that RGs and BSLs are non-equivalent. NIH must use these terms consistently across all policy sections.
4) BMBL Functionality & Misconception: The Biosafety in Microbiological and Biomedical Laboratories (BMBL) manual does not assign Risk Groups; it provides Agent Summary Statements with recommended Biosafety Levels. A regulatory condition referring to an RG classification 'in the BMBL' cannot be fulfilled.
5) Jurisdictional Ambiguity: The phrase 'and any other applicable Federal, State, or local entities' introduces immense ambiguity. NIH must explicitly identify these entities, specify whether approvals are

sequential or concurrent, clarify coordination protocols, and establish resolution pathways when determinations conflict.
6) Overbroad Scope & Unintended Petition Backlogs: As written, the petition requirement could be interpreted as applying to non-pathogenic genetically modified constructs or benign RG1 organisms that are not explicitly named in the BMBL. NIH must explicitly clarify that unlisted, non-pathogenic RG1 agents do not require federal petitioning.
7) Reusable Determinations & Response SLAs: Section III-D commits NIH to publishing determinations for lowering RG3/RG4 containment but omits determinations for emerging or novel agents. NIH should publish all containment determinations (agent, modification, approved containment, and rationale) in a searchable public database that other institutions may rely upon as established precedent. Furthermore, NIH must set a target response timeline (e.g., 30 calendar days) rather than relying on the subjective term 'timely.'
8) Definitive Source for Risk Group Assignments.
With Risk Group assignments removed from the former Appendix B and absent from the BMBL, NIH must provide an authoritative, version-controlled federal repository or clear objective criteria for assigning Risk Groups to non-recombinant agents. Without standardized federal classifications, institutions will reach conflicting conclusions for the same agent, compromising national oversight consistency.
9) Avoid Rigid Containment Prescriptions (GDMOs and Influenza Research). Rigid, one-size-fits-all containment rules conflict with performance-based risk assessment. A universal minimum of BSL-2 for Gene Drive Modified Organisms (GDMOs) does not map effectively to specialized containment systems (e.g., Arthropod Containment Level [ACL] guidelines, USDA/NCAR Greenhouse standards, or aquatic facilities). NIH should permit equivalent risk-based containment modalities and issue specialized guidance. Additionally, containment mandates for influenza constructs should specify exact phenotypic traits, host range, and pathogenicity markers rather than sweeping in constructs based on raw genomic segment proportions.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): None

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1) Refine the definition of a reportable incident and provide clearer thresholds for reporting to support a risk-based, consistent approach across institutions. Clear thresholds improve consistency and allow NIH to focus regulatory oversight on events with true potential public health or community significance.
2) Decouple Regulatory Reporting from Public Website Posting: Requiring institutions to publicly post unredacted investigative reports and meeting minutes for routine or minor incidents creates severe unintended consequences:
3) Publicly posted incident reports inadvertently provide sufficient detail to identify involved personnel.
4) Publicly linking Principal Investigators, grant numbers, and specific facility locations exposes researchers to harassment, physical threats, and targeted cyber-attacks, particularly in sensitive animal research domains.
5) Aggregated public postings reveal institutional research security information. Automated AI scraping tools can harvest these public records to map national high-consequence research capabilities, directly conflicting with federal research security directives and Select Agent regulations.
6) Forcing minor, fully mitigated events into public view suppress internal reporting of near-misses and

borderline events out of fear of public backlash or reputational damage.
7) Resolving Undefined Categories & Technical Definitions: To eliminate ambiguity, prevent administrative overload, and protect local reporting culture, NIH must establish precise definitions for the following core terms in Section II:
Incident: A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.
Release (Loss of Containment or Occupational exposure): Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
Basic First Aid vs. Agent-Specific Medical Treatment: NIH must explicitly align medical treatment with OSHA standards (care beyond basic first aid). NIH must clarify that precautionary, non-specific post-exposure prophylactic (PEP) treatment or routine medical consultations do not constitute agent-specific treatment triggering 24-hour federal reporting.
Potential Exposure: Must be defined as an event occurring in the active presence of a biohazard where primary barriers or PPE were breached, creating a credible exposure pathway. Equipment or PPE failures occurring in the absence of active biohazardous agents are not potential exposures.

8) Compliance Violation vs. Administrative Non-compliance: Must distinguish administrative non-compliance (e.g., late paperwork, minor log errors) from substantive biosafety non-compliance (e.g., unapproved research initiation or unauthorized containment lowering). Administrative non-compliance and low-risk items must NEVER necessitate a 24-hour reporting timeframe.

9) Minor Spill: Must remove subjective terms like generally and define minor spills.
10) Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries.
11) NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports

6. Other feedback relevant to this resource: 1) Provide risk assessment guidance for self-aggregating proteins (Policy Sections II and V-A). The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.
2) Clarify oversight of computational and AI assisted work (Policy Sections II and V-C). Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological
3) Provide a minimum 24-month phased implementation period The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction

standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.
4) Pilot the policy and templates: NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.
5) Develop implementation resources: Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.
6) Address the cost of compliance: The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.
7) Allow flexible institutional models: The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

I thank NIH for allowing me the opportunity to provide comments on this Draft Policy. We look forward to seeing a second draft of the Policy and will remain fully engaged in this process.

Description: Comments to NIH biosafety policy

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Submitted to: National Institutes of Health, Office of Science Policy
Re: NOT-OD-26-112 — Draft NIH Biosafety Policy for Research Involving Biohazards
Date: October 15, 2026
Submitted by: William L. Redmond, PhD
Portland, Oregon

General Comments

I appreciate the opportunity to comment on the proposed NIH Biosafety Policy for Research Involving Biohazards. I strongly support NIH's objective of modernizing biosafety oversight and ensuring that research involving biological materials is conducted safely and responsibly. The proposed shift toward risk-based oversight, including provisions for delegated Institutional Biosafety Committee (IBC) review, is an important and welcome development.

I strongly believe that effective regulation must be grounded in scientific evidence, practical experience, and the actual biological risks associated with specific research activities. Rigorous biosafety oversight is essential, particularly when introducing novel technologies with uncertain risks. However, requirements appropriate for pioneering, higher-risk research should not automatically be extended to routine laboratory procedures that have been performed safely for decades under established institutional practices.

My principal concern is that the proposed expansion of IBC oversight could substantially increase administrative requirements for routine research involving primary human specimens, established cell lines, and well-characterized genetic modifications without providing corresponding improvements in safety. Such requirements could divert limited institutional resources from oversight of genuinely higher-risk activities, delay scientific discoveries, increase research costs, and ultimately impede the translation of promising treatments to patients with cancer.

The proposed expansion of IBC oversight must also be considered in conjunction with the policy's requirements for documentation and public disclosure of IBC proceedings. Bringing substantially more routine biomedical research under IBC review could significantly increase administrative burdens and create additional risks of inadvertent disclosure of unpublished scientific discoveries, proprietary research methods, intellectual property, and confidential research information.

I therefore encourage NIH to adopt a framework that preserves rigorous oversight of research presenting meaningful biological hazards while providing streamlined, risk-based review pathways for routine biomedical research. The following recommendations are intended to strengthen the proposed policy while maintaining the efficiency and innovation essential to translational biomedical research.

1. Research Involving Primary Human Specimens

Relevant provision: Section IV-2 — Research Requiring IBC Review and Approval Before Initiation

The draft policy identifies research involving primary cells that may be contaminated by adventitious agents as requiring IBC review and approval before initiation.

This provision could encompass an extraordinarily broad range of biomedical research, including routine laboratory studies involving peripheral blood mononuclear cells (PBMCs), lymphocytes, human tumor biopsies, surgical specimens, tumor-infiltrating lymphocytes (TILs), primary tumor cultures, and patient-derived organoids.

These materials are essential to contemporary translational cancer research and are routinely handled under established institutional biosafety practices, including appropriate BSL-2 precautions and universal precautions for potentially infectious human specimens.

Although primary human specimens can contain adventitious infectious agents, the mere possibility of such contamination should not automatically require separate protocol-specific review by the full IBC.

It is important to distinguish between routine handling of potentially infectious human specimens and experimental procedures that intentionally propagate infectious agents, increase exposure risks, or introduce additional biological hazards.

Recommendations

A. Establish streamlined institutional review mechanisms.

NIH should permit institutions to approve routine collection, processing, culture, and analysis of primary human specimens through institution-wide or laboratory-specific biosafety registrations.

Such approvals could cover defined classes of specimens and experimental procedures rather than requiring separate IBC submissions for every scientific research protocol.

B. Permit delegated review of routine human specimen research.

Routine research involving primary human tissues and cells should be eligible for delegated review by an institutional biosafety officer or designated IBC member when established containment procedures are appropriate and no additional biological hazards have been identified.

C. Reserve full IBC review for activities involving increased biological risk.

Full IBC review should be required when experimental procedures introduce hazards beyond those associated with routine specimen handling, including intentional propagation of infectious

agents, modifications increasing pathogenicity or transmissibility, or procedures requiring higher levels of containment.

D. Clarify the meaning of "may be contaminated by adventitious agents."

Without additional clarification, this language could encompass virtually all primary human specimens. NIH should specify how institutions should evaluate the likelihood and consequences of contamination and whether routine BSL-2 practices adequately mitigate the associated risks.

Suggested Policy Language

"Research involving routine collection, processing, culture, or analysis of primary human cells and tissues, including blood-derived cells and tumor specimens, may be reviewed and approved through an institutional biosafety registration or delegated review process when the activities are conducted under established containment practices and do not involve intentional propagation of infectious agents or other procedures introducing additional biological hazards.

Separate protocol-specific IBC approval shall not be required for activities covered by an approved institutional or laboratory-specific biosafety registration, provided that the activities remain within the scope of the approved risk assessment."

2. Research Involving Established Human Cell Lines

Relevant provision: Section IV-3 — Research Eligible for Delegated Review

The proposed policy appropriately recognizes that research involving well-characterized cell lines may be eligible for delegated review.

This is an important distinction because established human cell lines are among the most widely used experimental systems in biomedical research.

Cancer research laboratories routinely employ established tumor cell lines for studies of antigen expression, immune recognition, tumor biology, drug sensitivity, vaccine development, and mechanisms of resistance to immunotherapy.

These studies may involve hundreds of experimental variations using the same cell lines without materially changing the underlying biosafety risks.

Requiring repeated biosafety submissions for routine experimental modifications would add administrative burden without necessarily improving laboratory safety.

Recommendations

A. Establish a clear definition of well-characterized cell lines.

NIH should clarify that well-characterized cell lines include established human and animal cell lines with documented identity, provenance, and appropriate biosafety characterization.

The definition should not depend solely on whether a cell line was obtained from a commercial repository. Research laboratories frequently develop and maintain extensively characterized cell lines that are not commercially distributed.

B. Permit laboratory-wide registration of established cell lines.

Institutions should be permitted to approve the use of defined categories or collections of established cell lines under a single laboratory biosafety registration.

Addition of another cell line with an equivalent risk profile should not automatically require a new IBC protocol.

C. Exempt routine experimental changes from repeated review.

Changes in culture media, cytokine exposure, drug treatment, antigen expression analysis, immune-cell coculture, and similar procedures should not require additional IBC approval unless they materially alter the biological hazard.

D. Differentiate established cell lines from cell lines with specific hazards.

Full IBC review should remain available for cell lines containing replication-competent pathogens, producing infectious agents, or presenting other identifiable risks requiring enhanced containment.

Suggested Policy Language

"Research involving well-characterized established cell lines may be conducted under laboratory-specific or institutional biosafety registrations approved through delegated review.

Routine experimental modifications, including changes in culture conditions, noninfectious treatments, and cellular assays, shall not require additional IBC review unless they introduce new biological hazards or materially alter the approved biosafety risk assessment.

Institutions may establish procedures for adding cell lines with equivalent biosafety characteristics to an existing approved registration."

3. Research Involving Genetically Modified Cells and Viral Vectors

Relevant provisions: Sections IV-2, IV-3, and V-B

The proposed policy requires IBC review for research involving genetically modified cells, viruses, and organisms while allowing delegated review for certain lower-risk experiments, including those involving genetically modified Risk Group 1 agents and replication-incompetent, nonintegrating viral vectors expressing low-risk transgenes.

I support the concept of tiered oversight. However, the proposed distinctions may not adequately reflect the diversity of genetic engineering methods routinely used in contemporary biomedical research.

Genetic modification is now a standard laboratory technique employed to investigate gene function, tumor antigen expression, immune recognition, cellular differentiation, and mechanisms of disease.

Examples include expression of tumor-associated antigens or noncanonical proteins in established cell lines, introduction of T-cell receptors into cultured lymphocytes, CRISPR-mediated gene knockout or modification, transient expression of reporter genes, use of replication-defective lentiviral or retroviral vectors, and genetic modification of tumor cells for studies of immune recognition.

These approaches have markedly different biological risk profiles.

The use of genetic modification alone should not determine whether a protocol requires full IBC review. Instead, the level of oversight should reflect the actual hazards associated with the modified cells, vectors, expressed products, and experimental procedures.

Recommendations

A. Expand delegated review to additional categories of low-risk genetic modification.

NIH should consider extending delegated review eligibility to well-characterized replication-defective integrating vectors, including selected lentiviral and retroviral vector systems, when the overall risk assessment supports this approach.

Although integration introduces additional considerations, it does not necessarily justify full IBC review for every experiment.

B. Differentiate genetic modifications according to their biological consequences.

The risk assessment should consider whether a modification increases pathogenicity or transmissibility, produces an infectious or replication-competent agent, alters host range or tissue tropism, introduces a toxin or other hazardous gene product, or otherwise increases risks to laboratory personnel or the environment.

Routine expression of nonhazardous proteins, reporters, or tumor antigens should generally qualify for streamlined review.

C. Permit platform-based approvals for commonly used vector systems.

Institutions should be able to approve defined vector platforms and associated laboratory procedures through a single biosafety registration.

For example, a laboratory routinely using a characterized replication-defective lentiviral vector platform to express nonhazardous proteins should not require an entirely new IBC protocol for each transgene, provided the new construct does not materially change the biosafety risk assessment.

D. Establish a streamlined amendment process.

Minor changes involving nonhazardous transgenes, reporter constructs, or experimental targets should be eligible for administrative or delegated review.

Full IBC review should be reserved for modifications that materially increase biological risk.

E. Distinguish genetically modified producer cells from final investigational products.

In cancer vaccine and cell therapy development, genetically modified cells may be used to manufacture products that do not themselves contain viable genetically modified cells or replication-competent vectors.

NIH should clarify that biosafety assessments of manufacturing activities and final products should be based on their respective hazards.

A final nonreplicating, nonintegrating, cell-derived vaccine product should not automatically be assigned the same biosafety risk classification as the genetically modified cells used during its manufacture.

Suggested Policy Language

"Research involving genetically modified cells or viral vectors shall be assigned to an appropriate level of oversight based on the biological characteristics of the modified material, the properties of the introduced genetic elements, the potential for replication or dissemination, and the risks associated with the proposed experimental procedures.

Delegated IBC review may be used for research involving well-characterized replication-defective vector systems and genetic modifications that do not materially increase biological hazards, when supported by a documented institutional risk assessment.

Institutions may approve established genetic modification platforms through laboratory-specific biosafety registrations. Changes in transgenes or experimental constructs that do not materially alter the approved risk assessment may be addressed through streamlined amendment procedures."

4. IBC Documentation, Public Disclosure, and Protection of Confidential Research Information

Relevant provisions: Delegated IBC Review, IBC Meeting Minutes, and Public Disclosure Requirements

The proposed NIH Biosafety Policy would require actions approved through delegated review to be reported "in full" at the next scheduled Institutional Biosafety Committee meeting and documented in the meeting minutes. The policy also provides for public posting of approved IBC meeting minutes, subject to allowable redactions.

While transparency and institutional accountability are important objectives, these provisions raise significant concerns regarding the disclosure of unpublished scientific research, intellectual property, proprietary research methods, confidential personnel information, and laboratory security-sensitive information.

These concerns are particularly important for translational biomedical research institutions conducting innovative research in cancer immunotherapy, vaccine development, genetic engineering, and investigational therapeutics, frequently in collaboration with biotechnology companies and pharmaceutical partners.

IBC protocols may contain detailed descriptions of experimental approaches, unpublished discoveries, novel constructs, proprietary manufacturing methods, and research strategies that have not yet been patented or publicly disclosed.

Public disclosure of such information could compromise intellectual-property protection, interfere with scientific publication, undermine contractual confidentiality obligations, and discourage academic-industry collaborations.

In addition, IBC records may contain information concerning laboratory locations, biological agent inventories, occupational-health considerations, personnel responsibilities, and security measures that should not be disclosed publicly.

The requirement that delegated approvals be reported "in full" is particularly concerning because it is unclear whether this refers to a complete description of the underlying research protocol or a complete accounting of the IBC's review and approval actions.

NIH should explicitly distinguish between complete internal documentation of biosafety decisions and the information necessary for meaningful public transparency.

Recommendations

A. Define the minimum information required in publicly posted IBC minutes.

NIH should establish clear and consistent standards identifying the information necessary to document IBC oversight and institutional accountability.

Public records should document the committee's actions, including quorum, recusals, risk determinations, approval conditions, and voting outcomes, as applicable, without requiring disclosure of confidential protocol-level scientific information.

B. Clarify the meaning of reporting delegated approvals "in full."

NIH should specify that this requirement refers to a complete accounting of delegated review decisions, including the nature of the activity, applicable risk classification, approval determination, and any conditions of approval.

It should not require public disclosure of complete research protocols, experimental methods, genetic constructs, unpublished findings, or other confidential scientific information.

C. Establish explicit and consistent redaction standards.

The final policy should authorize appropriate redaction of information involving unpublished scientific discoveries, patentable inventions, intellectual property, trade secrets, proprietary experimental methods, confidential sponsor information, personally identifiable information, occupational-health information, biological agent inventories, sensitive laboratory locations, facility vulnerabilities, and security controls.

NIH should provide clear guidance to promote consistent implementation across institutions and minimize uncertainty regarding permissible redactions.

D. Establish a reasonable period for public posting.

The requirement for immediate posting of approved IBC minutes could create substantial administrative and compliance burdens.

Institutions require sufficient time to conduct appropriate privacy, intellectual-property, security, legal, and communications review before releasing documents publicly.

NIH should establish a reasonable, defined posting period following approval of meeting minutes rather than requiring immediate publication.

E. Permit standardized public summaries while retaining complete internal records.

NIH should permit institutions to prepare standardized public summaries of IBC proceedings that provide meaningful information about biosafety oversight without disclosing confidential or security-sensitive information.

Complete, unredacted meeting minutes, protocol submissions, risk assessments, and supporting documentation should be maintained internally and made available to NIH and other authorized oversight authorities as required.

This approach would preserve regulatory accountability while reducing the risks associated with public disclosure.

Suggested Policy Language

"Institutions shall maintain complete internal records of IBC proceedings, delegated reviews, risk assessments, approval determinations, and associated supporting documentation.

Publicly available IBC records may consist of appropriately redacted meeting minutes or standardized summaries that document committee actions, risk classifications, approval decisions, conditions of approval, quorum, recusals, and voting outcomes, as applicable.

Reporting delegated approvals 'in full' shall require a complete accounting of the review actions and determinations but shall not require public disclosure of complete research protocols or confidential scientific, proprietary, personnel, occupational-health, or security-sensitive information.

NIH shall establish uniform standards for permissible redactions and a reasonable period following approval of IBC minutes for institutions to complete appropriate confidentiality, intellectual-property, privacy, legal, and security reviews before public posting.

Complete, unredacted records shall be retained by the institution and made available to authorized oversight authorities as required."

5. Avoiding Duplicative Oversight and Unnecessary Administrative Delays

An overarching concern is the potential for duplicative oversight across institutional review systems.

Biomedical research institutions already maintain established processes involving Biosafety Committees, occupational-health programs, Institutional Review Boards, Institutional Animal Care and Use Committees, and other research compliance offices.

For studies involving investigational therapies, additional oversight is provided through FDA requirements and institutional clinical research governance.

Although these systems serve different purposes, unnecessary duplication of administrative review should be avoided.

NIH should explicitly encourage coordinated review and recognition of existing institutional risk assessments.

In addition, NIH should establish clear expectations for timely delegated review and distinguish between modifications that require prospective approval and routine changes that can be documented within an existing approved protocol.

NIH should provide model umbrella registrations, model public summaries, redaction examples, and implementation guidance before the policy becomes effective.

6. Conclusion and Requested NIH Actions

The proposed NIH Biosafety Policy presents an opportunity to modernize biosafety oversight while improving the efficiency of biomedical research.

I support NIH's objective of strengthening biosafety through a scientifically grounded, risk-based framework. However, achieving that objective requires distinguishing research involving meaningful biological hazards from routine laboratory procedures conducted under well-established containment practices.

I encourage NIH to incorporate the following principles into the final policy:

1. Permit institution-wide or laboratory-specific biosafety registrations for routine studies involving primary human specimens.
2. Expand delegated review eligibility for low-risk research involving human tissues, established cell lines, and well-characterized genetic modifications.
3. Allow platform-based approvals for established cell culture and viral vector systems.
4. Require additional IBC review only when experimental changes materially alter the underlying biosafety risk assessment.
5. Distinguish the risks associated with genetically modified manufacturing systems from those associated with final investigational products.
6. Establish clear standards for public disclosure of IBC proceedings, including minimum reporting requirements, permissible redactions, and reasonable timelines for public posting.
7. Permit standardized public summaries of IBC decisions while requiring institutions to retain complete, unredacted records internally, thereby protecting unpublished scientific discoveries, intellectual property, confidential personnel information, and laboratory security-sensitive information.
8. Promote coordination with existing institutional and federal oversight systems to avoid unnecessary duplication and delays.

NIH has an opportunity to establish a modern framework that directs regulatory attention and institutional resources toward research presenting meaningful biological risks while allowing routine biomedical research to proceed efficiently under established safety practices.

The success of this policy should ultimately be measured not by the number of protocols subjected to review, but by its effectiveness in protecting research personnel, patients, and the public while enabling responsible scientific innovation.

Regards,

William L. Redmond, PhD

233. Gregory Park

I am responding: On behalf of myself

Name: Gregory Park

Name of Organization: University of Minnesota

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Life science research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Appropriate attempt, but clarifications are needed in the definitions, or if there is flexibility within the scope, then statements must be made that allow institutional flexibility in the interpretation and application of scope with the spirit of the Policy in mind. Describing scope is a difficult process because there are exceptions that present both high and low risk situations that are just not easy to account for in policy language.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered oversight is important, and empowering local oversight is most important for this NIH Biosafety policy. I think your draft does an acceptable job of this. Unfortunately, I think many comments are going to be submitted that bring up perceived gaps in the NIH Biosafety Policy because no institution or organization subject to the policy wants to get it wrong. Without some language that pardons institutions/organizations from making decisions to fit their circumstances in the spirit of the policy that was written (protection of human health, transparency, etc.), groups are going to be filling your comment sections with requests for clarifications and specific needs so they can ensure that they are not making wrong decisions and are then subject to penalties. And, the policy does not seem to explicitly state that local oversight should make decisions for all perceived gaps in order to implement the policy framework. The recommendations to gain clarity and make decisions result in making interpretation so complicated, it actually raises more questions and takes power away from local oversight. It also makes implementation more difficult for institutions and groups that vary in size and scope of research, but yet are subject to the Policy.

3. Continued utility of Risk Groups: Risk group utility is an important baseline that should be used, but there is not a standard federal reference document that labels every agent with a risk group nor modified agents, naturally occurring variants, and emerging/novel agents. Additionally, use of BSL from the BMBL also doesn't always account for modified agents, all naturally occurring variants/strains, and appropriate BSL flexibility guidance. Thus, the IBC is a great way to allow local decision making. If the NIH Guidelines and BMBL are continually used as a references for guidance in many situations, but not as strict decision makers, then IBCs should be afforded the flexibility to make decisions as they see fit. If

anything, a set of guidelines that describe when certain BSL must be followed, may be a better way to keep high risk research from unusual IBC decisions that fall outside the spirit of the NIH Biosafety Policy.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: With changes in software, accessibility, compatibility, and institutional size, the strict adherence to incident reporting and meeting minutes templates is not ideal. It is better to offer up that components of these should be included, but use of the templates should be optional.

6. Other feedback relevant to this resource: I think many comments will be submitted that want empowerment of BSOs. BSOs, as a role on the IBC with specific duties mutated from their introduction to became the focus and pinnacle position for an entire industry, where the spirit of the role was changed to something authoritarian as biosafety professionals seemed to feel they would only be listened to in requesting resources and assistance if they had a powerful title. I think the empowerment of the BSO is misguided, but the plight is real. Some want to believe the BSO is akin to an Attending Veterinarian or a Chief of Police and want a federal agency to say as much. What is more important is ensuring that biosafety expertise of a certain kind is necessary and involved when research of a certain kind is being performed. Too often, biosafety professionals do not recognize the biosafety expertise of the faculty at institutions who simply need to be informed of a different lens when considering safety, and even worse, they find them as adversaries instead of partners. Instead of spending time empowering BSOs in the NIH Biosafety Policy, biosafety professionals need to seek out stronger collaborations with their IBCs to empower biosafety compliance and seek out resources with institutional administration.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): molecular microbiology, infectious diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Biohazard definition is TOO broad. The vast majority of the biomaterial in research pose minimal hazard.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Not at all appropriate. Too much overnight. Waste of time and resources at every level.

3. Continued utility of Risk Groups: it is fine

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): not needed

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Not necessary to have a uniform template

6. Other feedback relevant to this resource: It is mostly useless and unnecessary

Name of Organization: University of Idaho

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Academic Research with Biohazardous Materials

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: • The Scope (p. 3) explicitly excludes plants from items 2 and 4 ("cells, viruses, or organisms, other than plants…"). If the intent is to cover genetically modified plants, the language should be revised to remove "other than plants" or include a separate plant-specific provision.
• If genetically modified plants are intentionally excluded, the policy should clarify which oversight mechanism or regulatory body is responsible for monitoring these activities to avoid potential gaps in oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed framework expands committee reviews, mandates three-year protocol renewals, requires public posting of minutes and incident reports, and extends requirements to all NIH-funded institutions. We urge NIH to ensure these administrative burdens are proportionate to the safety benefits through a risk-based approach.

Specifically, we recommend the following:
• Compliance Violations: The requirement to report "any compliance violations" is overly broad. NIH should provide specific examples (e.g., failure to obtain IBC approval, containment breaches) and clarify reporting pathways.
• BSO Role: We suggest additional guidance on the BSO's authority to suspend risky activities, their responsibility for equipment records, and coordination with occupational health. We also suggest requiring a BSO for BSL-2 labs working with DGOF agents.
• Training & Near Misses: Clarify if PIs may conduct training independently or if BSO/IBC involvement is required and define minimum standards. Regarding near-miss reporting to NBDSAC, please clarify the designated submitter and whether local records should feed into a national repository.
• Public Disclosure: Publicly posting all incident reports may discourage candid self-reporting due to reputational risks. We suggest balancing transparency with the need to maintain a strong reporting culture

3. Continued utility of Risk Groups: The policy requires that risk assessments be available (pp. 5-6) and IBC approvals be documented in meeting minutes (pp. 6-7). We request guidance on whether full risk assessments should be included in posted minutes, referenced via a link/identifier, or stored in a separate public repository. Clear expectations will promote consistency and reduce administrative burden.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The University of Idaho supports efforts to encourage voluntary adoption of biosafety best practices for research not otherwise subject to the policy. Clear guidance, streamlined reporting mechanisms, and educational resources may promote broader participation without creating unnecessary administrative burden.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We support the draft incident reporting template for its concise approach to consistent data collection. Regarding the other templates/requirements, we suggest the following:

• Minutes Template: The current level of detail is burdensome and often duplicates information found in approved protocols. We encourage a more streamlined format that focuses on committee deliberations and decisions rather than recreating redacted protocols.
• Posting Timeline: Please clarify if draft minutes must be posted publicly before approval, or if only approved minutes should be posted following the subsequent meeting (pp. 6-7).
• Basic First Aid: For incidents requiring only first aid (Section III.B), we suggest NIH define "basic first aid" or reference an authoritative resource and clarify any associated documentation requirements.

6. Other feedback relevant to this resource: The University of Idaho believes additional implementation guidance would be most valuable in the areas discussed above, including:
• Public posting of meeting minutes and expectations regarding draft versus approved minutes.
• Definitions and documentation requirements associated with basic first aid.
• Reportable compliance violations and reporting pathways.
• Biosafety Officer authority and responsibilities.
• PI training responsibilities and minimum training expectations.
• Near-miss reporting responsibilities and local recordkeeping expectations.
• Availability and public accessibility of risk assessments.

Description: NIH Biosafety Draft Policy Comment Letter from University of Idaho Vice-President of Research and Economic Development

237. Helen Rappe Baggett

I am responding: On behalf of myself

Name: Helen Rappe Baggett

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/15/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Some scope of work requiring IBC review is not well defined, and these definitions should be tied to biosafety hazard.

-Research with prions or other self-aggregating proteins
-Research with well-characterized cell lines
-Primary cells that may be contaminated by adventitious agents.
It is unclear if this would include ALL work with primary human cells or NHP cells or tissues.

Additionally, this policy does not permit any exemptions. Work that was previously exempt from review under the NIH Guidelines Section F will now require IBC review, including all plasmids and transgenic animals. This will add significant administrative burden without meaningfully impacting safety. It is recommended that NIH maintain the previously established categories of exempt research. NIH describes the purpose of the modernization as expanding oversight to biohazards while "removing red tape for low-risk research" and specifically asks commenters whether the proposed tiered oversight is appropriately calibrated to risk and administrative burden.
Exempt from IBC oversight is not synonymous with exempt from safe laboratory practice. Rather, it represents a determination that the incremental safety benefit of mandatory IBC oversight does not justify the administrative burden for a defined class of low-risk research. Currently exempt research was previously determined by NIH, following notice and opportunity for public comment, not to present a significant risk to health or the environment.

Update this draft policy to include exemptions for materials with a commonly understood low biosafety risk, such as well-characterized cell lines, presumed non-infectious primary cells/tissues, previously exempt transgenic animals, and vectors with no toxic or otherwise harmful inserts.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Risk Group must continue to be used as a baseline for risk assessment. Risk assessments for modifications to agents must have a starting point, and the risk group

for the wildtype agent is the logical starting point. Wildtype Risk Group should not be the default assumption for modified agents, but it provides a baseline of risk assessment that the expertise present in the IBC can use when deliberating whether the modifications enhance or decrease the risk of the agent. Only when the Risk Group is set can the appropriate Biosafety Level be assigned.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident Reporting: Requiring public posting of incidents is a bad idea. Adding in the requirement to identify the PI is even worse. This will only result in fewer incidents being reported, which means that biosafety professionals will not be able to identify trends and implement mitigation strategies, which means that more incidents may occur as a result. I don't see this policy as anything other than a punitive measure to publicly shame labs/PIs/institutions who have incidents. It will not improve safety or prevent the accidental release of agents.

It is recommended that NIH revise the approach to public posting of incidents so that detailed incident reports are submitted to NIH but are not routinely required to be posted publicly in their entirety. Alternatively, NIH could provide a template for public posting of standardized, de-identified high level summary information of incidents that might include root-cause categories and corrective actions. NIH could separately require disclosure of additional information when a particular incident presents a compelling public health or safety interest.

This approach balances transparency objectives with the equally important need to preserve a just, non-punitive reporting culture in which researchers and staff are encouraged to report incidents, near misses, and potential safety concerns promptly and completely. It also provides protections for researchers that are increasingly threatened or harassed due to the tools or subject matter of their research. Importantly, NIH would receive the information necessary to evaluate significant incidents, institutional responses, and compliance. The distinction would therefore be between information necessary for regulatory oversight and information necessary for public transparency, rather than assuming that the same level of detail is needed for both purposes.

6. Other feedback relevant to this resource: Scope of work lacking clear definitions:

Primary cells that may be contaminated by adventitious agents.
As written, “may be contaminated” could be interpreted to include virtually any primary human or animal cells (including any research involving NHP cells or tissues) for which the infectious-agent status of the source has not been comprehensively established.
NIH should define “adventitious agent,” establish a risk-based threshold for determining when contamination is reasonably anticipated, and clarify whether donor screening, testing, source information, or other documentation can establish that primary cells do not fall within this category. The Policy should also clarify its application to commercially obtained cells, repository specimens, patient-derived cells, and primary animal cells and provide examples of included and excluded materials. A merely theoretical possibility of contamination should not independently trigger IBC oversight; the definition should be tied to a known or reasonably anticipated potential hazard to human health. Clear criteria are necessary to avoid additional administrative burden by unnecessarily expanding IBC oversight

beyond research presenting a meaningful biosafety risk.

Well-characterized cell lines.
The Policy does not provide sufficiently objective criteria for determining when a cell line qualifies as well-characterized, creating the potential for inconsistent interpretations among investigators, biosafety professionals, and IBCs. NIH should specify what level of information regarding identity, provenance, biological characteristics, and adventitious-agent testing is necessary; whether established commercially available or widely used cell lines may be presumed to satisfy the definition; and how primary, immortalized, genetically modified, and patient-derived cells should be treated. NIH should also provide examples of included and excluded cell lines. Because this determination may affect the scope and level of institutional oversight, a clear, risk-based definition is necessary to ensure consistent implementation and avoid additional administrative burden by unnecessary review of research that does not present a meaningful biosafety risk.

Self-aggregating proteins.
IBC review is appropriate for the review of research involving prions or biospecimens identified to be from a person or animal known to have a prion-based disease. However, the term self-aggregating is not sufficiently defined to permit institutions or investigators to determine consistently if every protein that happens to aggregate or contributes to an aggregation-associated human disease, such as ALS, is also covered. Protein aggregation alone does not necessarily establish a meaningful biosafety hazard. NIH should clarify whether “other self-aggregating proteins” is intended to encompass proteins with prion-like, seeding, propagation, transmissibility, pathogenic, or other specified hazard characteristics rather than any protein capable of aggregation. The definition should identify objective criteria and provide examples of both covered and excluded materials.

Timeline for Implementation.
The timeline for institutional implementation and compliance with the revised policy should be at least a year after the publishing of the final rule instead of 6 months.
A six-month implementation period is insufficient given the breadth, complexity, and institutional impact. Revising electronic systems to accommodate the new regulations is a significant challenge that will likely prevent many institutions’ ability to meet this timeline. Additionally, updating policies and procedures and ensuring that researchers have the training they need to understand the new requirements, including newly covered areas of research, will require additional time. The time required to identify newly covered research is one reason why it is critical for entities to be held to realistic and achievable implementation timelines.

NIH should provide a detailed description of the required elements of an institutional assurance and publish accompanying implementation guidance before policy adoption, including model assurance language, implementation templates, and sufficient lead time for institutions to develop. Administrative burden should be kept in mind in considering required elements.

Human subjects' studies requiring IBC review.
Section IV-2 outlines the only clinical research provision and specifically identifies IBC review for biohazards that shed, replicate, integrate, require higher-risk manipulation, or involve RG2 or higher

wild-type agents. There is no discussion of other genetically modified agents being used in clinical research, such as plasmids or RNA, and no discussion of exemptions. Given the https://www.hhs.gov/press-room/hhs-launches-clinical-trials-reform-initiative.html, additional administrative burden should not be introduced by expanding IBC oversight in the clinical research arena.

The Policy should also exempt any covered clinical research studies from mandatory three-year de novo IBC review or permit an administrative continuation process confirming that no material changes affecting biosafety have occurred. Full IBC review should be required only for clinical research presenting local biosafety risk, where there may be questions regarding product handling and possible shedding. This approach would maintain appropriate biosafety oversight while reducing unnecessary regulatory burden

Uploaded File: 2026-10-NIH-biosafety-policy-comments-SRosenberger.docx

National Institutes of Health (NIH) Draft Biosafety Policy for Research Involving Biohazards, dated 8/19/2026 https://grants.nih.gov/grants/guide/notice-files/NOT-OD-26-112.html

The new biosafety policy incorporates major components of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines) while adding pathogens and materials that could negatively impact human health that many Institutional Biosafety Committees (IBCs) already review. Therefore, these comments solely include suggestions for clarification or revision. Thank you for the opportunity to review and your consideration.

For context, continued overlap:

- Human Immunodeficiency Virus, Hepatis B virus and human blood, bodily fluids, tissues, cells/cell lines that are not genetically modified are still regulated by the Occupational Safety and Health Administration's (OSHA) Bloodborne Pathogens and have additional Biosafety Level guidance in Centers for Disease Control (CDC)/NIH's Biosafety in Microbiological and Biomedical Laboratories (BMBL), 6th edition (2020)

For context, deletions from the NIH Guidelines that are not in the new biosafety policy or perhaps will be provided in guidance documents:

- Some experiments in Section III-C – Experiments involving human gene transfer
- Providing a set of experiments for which the Principal Investigator can notify the IBC simultaneous with initiation
- Exemptions for low risk host-vector systems (*E. coli* K-12, *Saccharomyces, Kluyveromyces, Bacillus subtilis, Bacillus licheniformis*)
- Exemptions for some activities involving transgenic rodents: purchase, transfer, generation of the majority of Biosafety Level 1 (BSL1) transgenic rodents via breeding
- Appendix G covering work practices, personal protective equipment and facility/physical containment criteria for BSL1, BSL2, BSL3 and BSL4, presume will defer to CDC/NIH's BMBL Biosafety Level criteria
- Appendix K covering large scale (greater than or equal to 10 liters of culture) work practices, personal protective equipment and facility/physical containment criteria also covered in CDC/NIH's BMBL Appendix M – Large-scale biosafety.
- Appendix N covering animals that typically require housing outside of laboratory conditions, e.g. nonhuman primates
- United States Department of Agriculture (USDA) will instead cover genetically modified plants and non-zoonotic livestock pathogens

Draft NIH Biosafety policy for Research Involving Biohazards – section, requirement	Clarify	Revise	Comments
Scope: Research involving biohazards is defined as research involving known or potential risk to human health and any of the following: 1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans; 2. Cells, viruses, or organisms, other than plants, that have been genetically modified; 3. Toxins, prions, and other self-aggregating proteins; or 4. Cells or organisms, other than plants, containing 1, 2, or 3 above.	X	X	1. Biological agents: a. Includes opportunistic human pathogens? b. Includes biological agents that per the literature are pathogenic solely for immunocompromised people? c. Includes cells/cell lines that an institutional risk assessment assigns Biosafety Level 1 as per CDC/NIH's BMBL Appendix H: Working with Human, Non-Human Primate (NHP), and Other Mammalian Cells and Tissues? Examples: i. Mouse cell lines from the American Type Culture Collection (ATCC) that are not known to contain an adventitious human pathogen? ii. Cells derived from food grade sources, i.e. obtained from USDA inspected facilities?

Draft NIH Biosafety policy for Research Involving Biohazards – section, requirement	Clarify	Revise	Comments
Scope: (continued) Research involving biohazards is defined as research involving known or potential risk to human health and any of the following: 1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans; 2. Cells, viruses, or organisms, other than plants, that have been genetically modified; 3. Toxins, prions, and other self-aggregating proteins; or 4. Cells or organisms, other than plants, containing 1, 2, or 3 above.	X	X	2. Cells that have been genetically modified – per the policy definition 'genetic modification' includes stable alterations into the genome by passaging, chemical or radiological means. a. Does this include passaging cells/cell lines? i.e. Masters JR and Stacey GN. Changing medium and passaging cell lines. Nat Protoc. 2007;2(9):2276-84, PMID: 17853884 b. Can the NIH Guidelines Appendix C-1 exemption be incorporated into the new policy? Example: cells immortalized by lentivirus vector or retrovirus vector transduction. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (2024) (NIH Guidelines) Appendix C-1 currently provides an exemption from IBC approval for "recombinant or synthetic nucleic acid molecules containing less than one-half of any eukaryotic viral genome…that are propagated and maintained in cells in tissue culture…with the exceptions listed in Appendix C-I-A." 3. Toxins – per the policy definition 'a protein or peptide produced by living organisms that causes harm in humans'. For toxins <u>not</u> on the Select Agent list: a. Are there toxins outside a specific LD_{50} range that could be excepted from IBC review and approval if already reviewed by institutional chemical safety personnel? b. Are toxin subunits included, e.g. diphtheria toxin subunit A? 4. Self-aggregating proteins (<u>not</u> prions) – per the policy definition 'misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals' - in vitro research included if no oral, permucosal or percutaneous risk demonstrated in the literature? a. Per the literature transmission of misfolded amyloid, alpha-synuclein or tau is primarily by the intracranial route, an unanticipated route of exposure for laboratory personnel. b. Misfolded alpha-synuclein - understood that there is literature demonstrating a possible gut to vagus nerve misfolded alpha-synuclein transmission route to the central nervous system, i.e. potential oral route. c. Amyloid aggregate literature examples: i. Banerjee G et al. Risk of transmission of amyloid β pathology via transfused blood products. Lancet. 2026 Aug 22;408(10556):753-760 PMID: 42624157 "risks of (blood) transfusion-related transmission of amyloid β pathology are currently undefined" ii. Tjornberg LO et al. Transmissable amyloid. J Intern Med. 2016 Aug;280(2):153-63. PMID: 27002185 "However, healthy (human) subjects without inflammation are not susceptible to AA amyloidosis, in contrast to prionoses, but may become primed and develop the disease at a later time-point."

Draft NIH Biosafety policy for Research Involving Biohazards – section, requirement	Clarify	Revise	Comments
Section III-A Responsibilities of the institution - IBC Functions	X	X	1. Per the policy the IBC must…use the required meeting minutes template. Re: the 'NIH Institutional Biosafety Committee Meeting Minutes Draft Template': a. Please provide a template that adheres to federal digital accessibility requirements (Americans with Disabilities Act Title II Regulations Subpart H – Web and Mobile Accessibility https://www.ada.gov/law-and-regs/regulations/title-ii-2010-regulations/#-35200-requirements-for-web-and-mobile-accessibility) b. Inspections/Ongoing Oversight – separate section vs. including 'last inspected' date in each IBC review? i. Is NIH specifying a laboratory inspection frequency? ii. Is NIH requiring IBCs to approve laboratory inspection results? (Per the template: "Discuss the results of laboratory inspections previously granted conditional approval based on correction of deficiencies discussed at a prior meeting.") 2. Per the policy 'approval should be granted for a period not to exceed three years, at which time a *de novo* registration submission and review is required.' Please keep as 'should'. a. If this were a 'must' this new requirement would increase logistic complexity. For IBC registrations that incorporate an animal protocol for which there is also a federal requirement for *de novo* protocol approval every three years, what happens if the IBC and animal protocol expirations are out of sync? Must they harmonize? Which is more important? b. If this were a 'must' this new requirement would increase administrative burden. i. Per the policy, IBC Functions still include "Periodically reviewing approved research conducted at the institution, to ensure compliance with the conditions established in the IBC approval and with the Policy." Institutions therefore typically perform an annual IBC protocol review with the Principal Investigator (PI) to verify protocol accuracy, a laboratory inspection has verified containment conditions, the personnel list is up-to-date, and personnel have been trained. This review may be performed by a Biological Safety Officer (BSO). ii. Per the policy, IBC Functions will already include measures to ensure IBC protocols remain up to date: "During the approval period, any changes to the approved research that have potential impact on the original biosafety assessment must be reviewed and approved by the IBC, or its delegate, before such research is conducted." iii. A *de novo* review requires that an IBC reviewer (generally a PI who should be focusing on research activities) re-do the meeting minutes template components even if work has not changed. In those cases, i.e. administrative updates only, a briefer format be used in the minutes, e.g. IBC PI name, IBC registration number/institutional tracking number, list of biological agents and the Committee reviewer's name?

Draft NIH Biosafety policy for Research Involving Biohazards – section, requirement	Clarify	Revise	Comments
Section III-A Responsibilities of the institution - IBC Functions (continued)	X	X	2. Per the policy 'approval should be granted for a period not to exceed three years, at which time a *de novo* registration submission and review is required.' (continued) b. If this were a 'must' this new requirement would increase administrative burden. (continued) iv. For administrative flexibility please maintain that an expiration date is optional. Rationale: a) An IBC reserves the right to terminate a protocol for noncompliance at any time. b) PIs that know they may easily resurrect, via IBC notification, a previously-approved IBC experiment they remove from their protocol tend to keep protocol length to actively performed work and/or animal protocol experiments as required by NIH Grants Policy Statement 4.1.1.2. v. If an expiration date will be required, please consider extending to a) 5 years to coincide with R01 grant duration, or b) for experiments that also require an animal protocol to 6 years in order to coincide with animal protocol expiration dates. Per NIH Grants Policy Statement 4.1.1.2. animal protocols must include all work proposed in an NIH grant even if the grant duration (5 years) extends past the animal protocol duration (3 years). 3. Per the policy "Reporting certain incidents to NIH that pose a significant risk to human health, using the required incident reporting template" including "any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approval." a. Please clarify 'maintain IBC approval' – does this mean failure to participate in 'periodic review'? b. For "administrative failures" (from the incident reporting template - Background) specifically "Failure to obtain or maintain IBC approval" (from the incident reporting template Part 2. Incident Information – What was the nature of the incident?) – please allow redaction of the Principal Investigator's name for: i. First-time incidents for Principal Investigators (PIs) who are new to the PI role (e.g. PostDoc receiving first faculty position) whose work will be assigned BSL2 or below and they met BSL requirements prior to seeking IBC approval. Rationale: Principal Investigators who are new to the PI role are still learning many of the administrative requirements that come with the PI role. Their name on an incident report could be of significant concern to them as they may think it could negatively affect their ability to seek NIH funding throughout the rest of their career.

Draft NIH Biosafety policy for Research Involving Biohazards – section, requirement	Clarify	Revise	Comments
Section III-B IBC membership		X	1. Per the policy, a "Biological Safety Officer (BSO) must be appointed when the institution conducts research subject to the Policy i) at BSL-3 or 4, or ii) involving GDMOs", and "(i)f an institution does not designate a BSO, the institution must assign another official to take on these responsibilities." Recommendation – any institution that falls under this policy must designate a BSO, even if that role is part-time. Rationale: this practice will ensure that at least one member of the IBC receives institutional support to attend 'appropriate training regarding laboratory safety and implementation' as per the policy Section III-A Responsibilities of the institution. This could include membership in ABSA International (the Association for Biosafety and Biosecurity) and inclusion in the ABSA International Communities discussion groups.
Section III-C Responsibilities of the Principal Investigator (PI)		X	1. Please include a requirement that the PI must sign the research protocol submitted to the IBC. This will ensure that the PI has reviewed the submission vs. delegated to a PI proxy. The signature may be in any form – wet ink, digital, electronic, email, etc. 2. For flexibility, if a PI proxy may be used to sign the research protocol submitted to the IBC, consider restricting to experiments covered by policy Section IV-3 – Research that requires review and approval before initiation and may be delegated to an individual or subgroup of IBC members.
Section IV Categories of Oversight for Research Based on Risk	X		1. Some research that currently falls under Section III-C of the NIH Guidelines for human research study participants may no longer require IBC review and approval. Will IBC approval still be required for: a. Messenger RNA (mRNA) if not self-amplifying? b. Gene editing methods such as CRISPR RNP (clustered regularly interspaced short palindromic repeats ribonuclear protein), CPE (Circular RNA-mediated Prime Editor) or would the human research study participant be considered a genetically modified organism? c. Adeno-associated virus (AAV) vectors since AAV vectors may integrate as per review article PMID: 35690906 and may shed. 2. Policy Section IV-3 – "Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members": a. For the IBC minutes template section "Readout of any projects approved by delegated review" – is that section meant to be inserted in the multipart 'New IBC Registrations and Amendments for Review' or can it be a separate section of the minutes?

Draft NIH Biosafety policy for Research Involving Biohazards – section, requirement	Clarify	Revise	Comments
Section IV Categories of Oversight for Research Based on Risk (continued)	X		2. Policy Section IV-3 – "Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members": (continued) b. Re: 'Research with genetically modified RG1 biological agents' where RG = Risk Group, will there be exceptions e.g. those previously covered by NIH Guidelines "APPENDIX C. EXEMPTIONS UNDER SECTION III-F-8: low risk host-vector systems (*E. coli* K-12, *Saccharomyces, Kluyveromyces, Bacillus subtilis, Bacillus licheniformis*)? c. Please clarify what 'Research conducted with transgenic organisms at BSL-1/ABSL-1' includes with regard to animals. Is it similar to the 'Animal experiments' table currently published for the NIH Guidelines? https://osp.od.nih.gov/wp-content/uploads/2022/11/Animal_Activities_Table.pdf d. Re: 'transgenic organism research at BSL-1/ABSL-1', are transgenic organisms currently assigned Arthropod Containment Levels (ACLs in CDC/NIH's BMBL Appendix E) included? e.g. *Drosophila, C. elegans*, pea aphids, USDA regulated plant pests e. For 'research with well-characterized cell lines', please define 'well-characterized' - any published in the literature? Tested for anticipated adventitious agents by sending lab?

239. University of Melbourne

I am responding: On behalf of an organization

Name: Matthew Gotch (on behalf of the Office of Research Management and the Pro Vice-Chancellor (Research Infrastructure), the responsible policy official)

Name of Organization: University of Melbourne

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): University of Melbourne maintains a diverse research program as a public university, though academic and professional staff in public health and infectious diseases contributed prominently in this feedback.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Please see in the attachment the University of Melbourne's formal comment on the new policy, which primarily addresses the appropriateness of scope as our central piece of feedback. We have also compiled some specific points of technical feedback within the form below.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 2. Appropriateness of tiered oversight and calibration to risk

We suggest that risk calibration should consider the characteristics of the actual material or system rather than relying on broad categories alone. Relevant factors include replication competence, attenuation, host range, pseudotyping, whether a viral system is single-cycle, and whether a technology edits genomic DNA or targets RNA without genomic modification. Treating replication-competent HIV, attenuated or single-cycle reporter systems, Cas9 and Cas13 technologies as functionally equivalent would not reflect their materially different risk profiles. Cas13 targets RNA and does not edit genomic DNA; when delivered in replication-incompetent lentiviral vectors, the risk profile differs markedly from DNA editors, yet the Policy does not distinguish these pathways.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates

The templates should support transparency without requiring disclosure that creates privacy, security, biosecurity or confidentiality risks. Mandatory publication of IBC minutes, incident reports, key

personnel contact details or detailed biosafety procedures may expose researchers and facilities, reveal security-sensitive operational information, or disclose confidential and proprietary research.

The incident reporting template should distinguish minor, contained events from significant incidents requiring broader notification. Public reporting without clear thresholds, context and explanation may create unnecessary alarm and obscure the distinction between routine laboratory events and matters presenting a material public health risk.

The templates should permit proportionate reporting, aggregation where appropriate, and redaction of personal information, security-sensitive details, proprietary information and information that could increase biosecurity risk. NIH should also recognise reporting already completed under equivalent domestic schemes and permit it to satisfy corresponding NIH requirements.

6. Other feedback relevant to this resource: 6. Implementation resources and additional guidance

Additional implementation guidance will be essential for foreign institutions, and we ask the NIH to consider:

A foreign-assurance pathway allowing institutions to demonstrate equivalent oversight through domestic regulatory and institutional arrangements.

Clear criteria for determining the relevant institution and legal-entity boundary, including co-located institutes, shared facilities and affiliated entities.

Worked examples covering primary human cells with endogenous or latent infection, replication-competent and attenuated viruses, pseudotyped and single-cycle systems, and DNA-editing compared with RNA-targeting technologies.

An equivalence framework mapping BSL requirements to recognised foreign containment standards, including Australian Physical Containment levels.

Guidance on how NIH requirements interact with existing domestic frameworks such as OGTR, SSBA, biosecurity and workplace safety requirements.

Criteria identifying when NIH approval is required before local IBC review of novel or emerging pathogens, together with expedited pathways for urgent public health research.

A foreign-assurance pathway allowing institutions to demonstrate equivalent oversight through domestic regulatory and institutional arrangements.

Clear incident-reporting thresholds, confidentiality protections and rules for redacting public minutes and reports.

Description: Formal feedback letter signed by Pro Vice-Chancellor (Research Infrastructure)

16 October 2026

NIH Office of Science Policy
6705 Rockledge Drive, Suite 630, MSC-7985,
Bethesda, MD 20892-7985

Dear NIH Office of Science Policy,

Subject: Response to Request for Information on Draft NIH Biosafety Policy for Research Involving Biohazards

The University of Melbourne appreciates NIH's extensive community engagement in developing the draft policy and acknowledges the comprehensive outreach undertaken through regional listening sessions, engagement with biosafety professional organisations, and consultation with Institutional Biosafety Committees and research institutions. Based on the engagement record published by NIH, the consultation process appears to have focused primarily on stakeholders within the United States.

We therefore welcome the current public consultation as an important opportunity for international institutions to contribute to the development of the policy. The University of Melbourne would like the opportunity to foreground concerns shared with many other research institutions in Australia in relation to the proposed scope of the new policy. In our view, both the proposed entity-wide scope of operation and jurisdictional overlap with pre-existing Australian regulatory regimes will produce significant compliance challenges.

Given the substantial participation of overseas institutions in NIH-funded research, we encourage NIH to give particular consideration to feedback from Australian institutions who are subject to mature biosafety regulatory schemes, and to ensure that the final policy appropriately accommodates institutions operating within these robust local regulatory environments which achieve aligned biosafety objectives.

Scope extends to non-NIH-funded research

The University supports NIH's objective of strengthening biosafety oversight for research supported by NIH funding. However, we are concerned that the draft policy extends beyond NIH-funded research and appears to apply to all research conducted at an institution that receives any NIH funding, regardless of whether the relevant project has any connection to NIH support.

The result of this is that research funded by Australian government agencies, industry sponsors and philanthropic organisations would potentially become subject to NIH governance requirements despite having no funding or scientific connection to NIH.

The comprehensive scope may also have a negative impact on international applicants, due to the potential cost of entity-wide compliance which may discourage Australian institutions from applying for, accepting or continuing NIH-supported research. For institutions with modest NIH funding, these costs may make continued participation untenable.

We respectfully submit that NIH's interests are most appropriately protected by attaching the Policy requirements to NIH-funded research and research directly connected to NIH-funded activities. Extending the Policy to all institutional research is disproportionate to the funding relationship and risks creating significant duplicative administrative burden without a corresponding improvement in biosafety outcomes (see further details on this under the heading “Overlap with Local Frameworks”).

We encourage the NIH to revise the Policy so that it applies only to NIH-funded research and research that directly supports or is materially linked to NIH-funded activities.

Overlap with local frameworks

The current NIH Guidelines recognise host-country regulatory frameworks and permit overseas research to be conducted under those frameworks where local biosafety practices are reasonably consistent with NIH expectations. This principle does not appear to have been carried forward into the draft policy.

Its omission is significant as, without a mechanism recognising equivalent foreign regulatory controls, institutions operating within mature biosafety frameworks may be required to comply concurrently with overlapping domestic and NIH policy requirements.

Australian universities undertaking biomedical research involving biohazards already operate under comprehensive regulatory and institutional oversight frameworks governed by an interlocking set of federal and state laws, sector regulators and technical standards:

- the Gene Technology Act 2000 and the Office of the Gene Technology Regulator (OGTR) control dealings with genetically modified organisms and related containment and licensing;
- the Biosecurity Act 2015 (Cth) provides national biosecurity measures at borders and for nationally significant pests and diseases;
- the National Health Security Act manages the secure handling of Security Sensitive Biological Agents;
- the Work Health and Safety (WHS) Acts and associated model regulations and Codes of Practice implemented by each state and territory set workplace duties for managing hazardous biological agents, risk assessment, containment, personal protective equipment and waste;
- the AS/NZS 2243 series on laboratory safety (microbiological safety and containment) prescribes containment levels, facility design, decontamination and laboratory practice;
- transport of infectious substances is regulated under the Australian Dangerous Goods Code and aligned UN/IATA dangerous goods rules; and
- institutional oversight is provided by research governance mechanisms such as institutional biosafety committees and human research ethics committees to ensure compliance with statutory and standards-based requirements.

Postal address:
Raymond Priestley Building, The University of Melbourne
Victoria 3010 Australia

Phone:
+61 3 8344 6872

These frameworks may use different terminology, classifications and administrative mechanisms, but seek to achieve equivalent biosafety outcomes as the draft Policy. We would welcome the opportunity to discuss the Australian framework further and respond to any questions.

Requiring foreign institutions to comply simultaneously with the proposed NIH policy and applicable domestic requirements could create material duplication and administrative burden, including:

- maintaining parallel risk assessment and approval processes;
- adapting institutional governance arrangements to satisfy overlapping oversight requirements;
- duplicative reporting and record-keeping obligations; and
- reconciling differing terminology, classifications and administrative requirements across frameworks.

Though both the proposed Policy and Australia's existing biosafety framework are designed to achieve robust biosafety outcomes, overlaying the two frameworks may create duplication that undermines the Policy's objectives. Requiring institutions to maintain parallel governance, approval and compliance processes would divert resources towards administration, create uncertainty regarding applicable requirements and reduce the agility of internationally collaborative and time-sensitive public health research. These additional burdens are unlikely to be accompanied by a corresponding improvement in biosafety outcomes, particularly where institutions are already operating within mature domestic regulatory and oversight frameworks.

We therefore encourage NIH to establish a proportionate pathway under which foreign institutions may demonstrate reasonably consistent compliance with the NIH policy objectives by operating within their local biosafety laws and frameworks. We consider a model centered on a single, institution-level Foreign Assurance, similar to that adopted by OLAW for animal welfare requirements, to be an appropriate precedent. This would enable appropriate NIH safeguards for escalation and significant incident reporting, while preserving the function of established frameworks at the local level.

Thank you for the opportunity to consult with the NIH and for your consideration of the University’s feedback.

Yours sincerely

[redacted]

240. QIMR Berghofer

I am responding: On behalf of an organization

Name:

Name of Organization: QIMR Berghofer

Type of Organization: Non-Profit Research Organization

Role: Other

Role - Other: Safety Advisor

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Medical research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We support effective biosafety oversight. However, it is unclear why this policy is extending NIH requirements to unrelated, non-NIH-funded research simply because an institute receives NIH funding.

Australian institutions already work under national and state requirements, supported by their own biosafety, biosecurity and research governance processes. Adding NIH requirements to this research would create overlapping obligations and substantial administrative work. Please explain what gaps this policy is intended to address specific to Australian research institutes, and what additional safety benefit it would provide.

At a minimum, please consider limiting mandatory application for overseas institutions to only NIH-funded research. If broader application is retained, institutions should be able to demonstrate how their existing regulatory and governance arrangements meet this new policy's objectives. Please outline how the additional requirements in this proposed policy would address any gaps left by Australia's stringent regulatory and governance arrangements.

Please also clarify what is meant by the "institution":
e.g.
1) how the requirements would apply to subrecipients, collaborators and shared facilities.
2) When do obligations begin and end as NIH funding changes.
3) Institutions need to understand the consequences for their other research before accepting an NIH award.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The level of oversight and detail required should match the risks of the research. Local committees review and approve work within their expertise. Please provide clearer guidance on when NIH review/ approval is also needed.

Section II allows research to proceed under another federal agency's oversight once the required approvals are in place. Please clarify whether this includes regulators outside the United States, and outline what institutions would need to provide for this oversight to be recognized.

Incident reporting should also reflect the risk involved in the incident. Minor paperwork or administrative errors that do not put anyone at risk should be treated differently from failures that could cause exposure or a release of biological material. E.g. For equipment faults, the reporting requirements should consider whether backup systems worked and kept the material safely contained. Would the NIH expect to receive reports on such incidents, even when said incidents occur outside of NIH funded projects.

Please note: Institutions have been, and are still responsible for investigating and improving such incidents. However, reporting biosafety events to the NIH should provide a clear safety benefit beyond the institution's own investigation and corrective actions already being made.

3. Continued utility of Risk Groups: Nil

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Nil

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The templates should clearly explain what information is required while allowing institutions to use their existing formats and refer to records already held.

Meeting minutes outline committee decisions, reasons and approval conditions. They should not need to repeat information already documented in applications, risk assessments, training records and supporting evidence. Copying this information into multiple records adds substantial work and increases the chance of inconsistencies.

Concerns regarding how much information would be made public, particularly for non-NIH-funded research. Detailed minutes and incident reports may contain confidential research, commercially sensitive information, staff health information or details that could affect institute security. Depending on the discussion, removing names may not be sufficient to prevent someone from being identified.

The proposal allows some information to be removed before publication, but clearer guidance is needed on how international institutions can meet their national and state legal requirements and confidentiality obligations. Please consider the addition of creating confidential detailed records, where required.

Please also explain the safety benefit of publishing reports of incidents that do relate directly to NIH funded projects. Mandatory publication to our institutes webpage using the NIH template could make staff less willing to report mistakes or speak openly during investigations.

6. Other feedback relevant to this resource: The proposed requirements would increase a substantial administrative burden across biosafety teams, committees, grant administration and other institutional

services.

Further guidance is needed on:

• What evidence is required for a Biosafety Assurance and when NIH may request more information.
• Will existing overseas regulatory approvals, committee arrangements and institutional records be accepted.
• Which non-NIH-funded projects would be considered relevant to this policy, and how long will the obligations to report to the NIH continue for.
• Additional examples of incidents that must be reported to NIH under this policy.
• What information must be published and how privacy, confidentiality and security will be protected.

Description: Nil

241. American Psychiatric Association

I am responding: On behalf of an organization

Name: Brooke Trainum

Name of Organization: American Psychiatric Association

Type of Organization: Professional Organization/Association

Role: Other

Role - Other: Policy director

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The American Psychiatric Association (APA) recommends that NIH make clear how institutions should assess requests to use service animals in laboratory settings, so that the policy supports both safety and access for researchers and trainees with disabilities. In September 2025, APA and American Psychological Association Services, Inc. asked the Centers for Disease Control and Prevention (CDC) to clarify language in Biosafety in Microbiological and Biomedical Laboratories (BMBL) stating that animals not associated with laboratory work are not permitted. We explained that treating this language as a categorical prohibition can exclude people who use trained service dogs, including people with psychiatric disabilities, from required coursework, research training, and scientific careers. We urged an individualized assessment of whether a service dog can be accommodated safely in the particular setting.
We appreciate the subsequent clarification issued jointly by CDC and NIH. It explains that the BMBL is advisory, does not address every situation involving service animals, and should not be used as a basis to deny reasonable accommodation. It also encourages institutions to conduct their own risk assessments in compliance with applicable law. This clarification is especially relevant to the proposed NIH policy, which identifies the BMBL as a primary handbook for risk assessment and would establish requirements for institutions receiving NIH funding.
APA recommends that NIH include the following principle in the final policy or accompanying implementation guidance: Institutions should evaluate requests involving service animals in laboratory

settings through an individualized assessment of the proposed activities, facility, potential exposures, and available risk mitigation measures, in coordination with appropriate biosafety and disability accommodation personnel. The BMBL's general guidance concerning animals not associated with laboratory work should not be applied as a categorical basis to deny a service animal accommodation. NIH should also incorporate this principle into training for institutional biosafety committees, biological safety officers, principal investigators, and other personnel who implement the policy. Practical guidance could address how to document the assessment, coordinate the accommodation and biosafety processes, consider measures tailored to the specific space and procedures, and revisit a decision if the research activities change.

242. Daniel Kiss

I am responding: On behalf of myself

Name: Daniel Kiss

Name of Organization: not applicable

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): RNA Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: major concern is that this new policy will enshrine an incorrect (and dangerous) definition of genetic modification as official NIH Biosafety policy. This is particularly dangerous for our member's research. I have once again quoted the problematic language below. In the "General Definitions" section, this document defines Genetic Modification as follows:

Genetic modification:
• The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
• Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
• Have the potential for one or more cycles of replication in a cell; or
• Can be transcribed or translated; or
• The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.

All current definitions of genetic modification center on techniques and experiments that caused permanent changes to the genetic material of the host cell or organism, in other words, their genomic DNA (or RNA for select viruses). However, as the highlighted text above shows, this proposed policy change ignores that decades-old scientific consensus. As the new language includes nucleic acids that "Can be transcribed or translated" this policy will incorrectly classify the vast majority of vaccine technologies as Genetic modifications even though no vaccine platform alters the genome of the recipient.

For example, under this definition, all mRNA vaccines (whose sole function is to be translated into antigen protein that trains the immune system), all virally-vectored vaccines (like the Oxford-AstraZeneca COVID-19 vaccine that has been given to ~2 billion people) which are transcribed into mRNA and then translated into the antigen, and selected live virus and virus-like particle vaccines will deemed genetic

modifications as per official NIH policy. Simply put, including the “Can be transcribed or translated” language as genetically modified is both scientifically wrong and irresponsible.

The confusion that would occur if NIH adopted this factually incorrect definition of genetic modification is a grave concern. For example, the dangers to public health and public trust by this inaccurate definition are enormous. It is easy to envision how anti-vaccine organizations can use this scientifically incorrect definition (which will become official NIH Biosafety policy) to push regulators and policymakers to weaponize the policy and its enforcement mechanisms. Even if anti-vaccine activists don’t attack companies, research institutions, or universities, they will certainly use the new official NIH policy to falsely claim that vaccines are genetically modifying patients. As such, this policy change could be used to further discredit the biotechnology sector, science, and scientists amongst the general public.

The “Can be transcribed or translated” language must be removed from the definition.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): This policy draft would force instant reorganizations within many institutions and would be difficult to enact.

Furthermore, by stating that a biosafety officer is required, but giving no credentials that need to be met for a person to serve in that role, this policy invites confusion

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The requirement of public-facing reports for any and all violations (even administrative ones) within 24 hours is overly burdensome and does nothing to increase the safety or rigor with which the research is conducted.

6. Other feedback relevant to this resource: N/A

Uploaded File: Expression-of-Concern_NIH.pdf

Description: My two largest concerns are spelled out

October 8, 2026

Dear NIH Leadership,

I'm writing to express my deep concern regarding NOT-OD-26-112, which is the Draft NIH Biosafety Policy for Research Involving Biohazards and is intended to replace the NIH's existing guidelines governing recombinant DNA research. I have many concerns regarding the new draft biosafety policy, but since space is limited, I will focus (and quote) two of the most troubling changes below.

As I am a researcher based in an academic research institution, this draft policy would impact me, my research, and our institution. Furthermore, the enforcement mechanism outlined in the new policy could apply to everyone receiving NIH funds -and would also reach into small businesses that are doing sponsored research at NIH fund receiving institutions. My central concern is that the proposed policies, as currently written, could easily be used to curtail vital research, confuse the general public, lead to further mistrust of science, and ultimately harm many institutions that conduct leading edge biomedical research. As the risk of potential damage to the scientific enterprise and many different institutions and companies is large, I'm writing to make sure that changes are made to the NIH's proposed Draft NIH Biosafety Policy for Research Involving Biohazards.

My first concern is that this 15 page policy statement overly simplifies the previous guidelines (which were 132 pages) by eliminating key examples and more explicit guidance regarding certain types of research. These changes open broad gaps in understanding where continuing certain experiments that have been considered standard practice for decades could be construed as (and possibly enforced as) policy non-compliance. That vagueness coupled with the enforcement language (quoted below) creates substantial risks to any institution that receives NIH funding.

> **Compliance and Enforcement**
>
> All institutions conducting NIH-supported research will be required to comply with this Policy, which will be included in the applicable terms and conditions of the award or agreement and included in applicable NIH intramural policies and procedures. As a term and condition for NIH funding, institutions shall ensure that any research conducted at or sponsored by the institution, irrespective of the sourc e of funding, shall comply with this Policy, as specified in applicable terms and conditions of the award or agreement.
>
> Failure to comply may provide a basis for enforcement actions, including, but not limited to, additional special terms and conditions, or termination, consistent with applicable grant regulations; applicable NIH policies and procedures, including NIH intramural policies and procedures; the Federal Acquisition Regulations; and/or other authorities, as appropriate. Enforcement actions may affect future funding decisions for the recipient institution, as authorized in the NIH Grants Policy Statement (GPS).

(All highlights and emphasis marks are mine)

The language above can be interpreted to threaten all NIH funding -both current and future- to an institution for actions deemed to violate the policy. That enforcement clause could be coupled with the policy's vague language to withhold research funds from institutions across the country. The policy requires that every incident report be posted on a public-facing institutional webpage for a minimum of five years, on NIH templates within 24 hours of the incident. Note, that the twenty-four hour reporting list includes administrative lapses such as failure to maintain IBC approval. So, an expired registration becomes a same-day federal report that is then posted publicly with NIH's response attached. In other instances, these public-facing incident reports could further erode trust between research institutions and their communities. Simply, if every infraction, no matter how minor an administrative lapse, must be reported publicly, then it's not hard to envision how opponents of scientific research can use those reports to claim that the community was placed at risk due to 'biosafety violations.'

My second major concern is that this new policy will enshrine an incorrect (and dangerous) definition of genetic modification as official NIH Biosafety policy. This is particularly dangerous for my research. I have once again quoted the problematic language below:

> **General Definitions**
>
> The following terms, which are used throughout the NIH Biosafety Policy, are defined as follows:
> … The first five definitions have been skipped …
>
> ***Genetic modification:***
>
> - The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
>
> - Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
> - Have the potential for one or more cycles of replication in a cell; or
> - Can be transcribed or translated; or
>
> - The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.

(All highlights and emphasis marks above are mine)

All current definitions of genetic modification center on techniques and experiments that caused permanent changes to the genetic material of the host cell or organism, in other words, their genomic DNA (or RNA for select viruses). However, as the highlighted text above shows, this proposed policy change ignores that decades-old scientific consensus. As the new language includes nucleic acids that "Can be transcribed or translated" this policy will incorrectly classify the vast majority of vaccine technologies as ***Genetic modification*** even though no vaccine platform alters the genome of the recipient.

For example, under this definition, all mRNA vaccines (whose sole function is to be **translated** into antigen protein that trains the immune system), all virally-vectored DNA vaccines (like the Oxford-

AstraZeneca COVID-19 vaccine that has been given to ~2 billion people) which are **transcribed** into mRNA and then **translated** into the antigen, and selected live virus and virus-like particle vaccines will deemed genetic modifications as per official NIH policy. Simply put, including the "**Can be transcribed or translated**" language as genetically modified is both scientifically wrong and irresponsible.

The confusion that would occur if NIH adopted this factually incorrect definition of genetic modification is a grave concern. For example, the dangers to public health and public trust by this inaccurate definition are enormous. It is easy to envision how anti-vaccine organizations can use this scientifically incorrect definition (which will become ***official NIH Biosafety policy***) to push regulators and policymakers to weaponize the policy and its enforcement mechanisms. Even if anti-vaccine activists don't attack companies, research institutions, or universities, they will certainly use this factually incorrect definition of genetic modification contained in this draft policy to falsely claim that vaccines are genetically modifying patients. As such, this dangerous definition of genetic modification could be used to further discredit the biotechnology sector, science, and scientists amongst the general public.

The simplest solution is to remove the "**Can be transcribed or translated**" bullet point from the definition of genetic modification.

Because the stakes are so high, I respectfully ask that NIH deliberate on this Draft NIH Biosafety Policy for Research Involving Biohazards and work to ensure that changes are made to this dangerous policy proposal.

Respectfully,

Daniel L. Kiss, PhD.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: To successfully transition from a recombinant DNA framework to a broader biohazard policy, the NIH must establish clear jurisdictional boundaries. Currently, the draft leans heavily toward human health hazards, leaving the oversight of animal, agricultural, plant, and environmental hazards ambiguous. For example, the rationale for removing genetically modified plants from the main framework is unclear and raises questions about where oversight for agricultural and ecological risks will reside.

Furthermore, foundational definitions require immediate clarification to prevent inconsistent institutional interpretations. The NIH must clearly define what constitutes "genetic modification" (e.g., does it include conventional mutagenesis or passaging?) and provide concrete examples of covered versus exempt activities. Similarly, the definition of "periodic oversight" must be specified to prevent institutions from building overly burdensome, non-standardized compliance systems. Finally, the NIH must explicitly define institutional applicability, detailing how the policy applies to affiliated hospitals, subcontractors, and projects funded by non-NIH sources at NIH-funded institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): We strongly support the introduction of delegated review for lower-risk work and the separation of Risk Group (RG) from Biosafety Level (BSL). However, these flexibilities require clear competency standards. The NIH must define the specific qualifications required for an IBC member to serve as a delegated reviewer and clarify the qualifications required for a Biological Safety Officer (BSO), distinguishing between the administrative assignment of the role and actual technical competency.

Additionally, the NIH must assess the cumulative workload of this "risk-based" system. Requirements for periodic oversight, de novo reviews every three years, expanded scope, and the new Biosafety Assurance could drastically increase administrative burden. Furthermore, the implications of the new Biosafety Assurance—specifically regarding institutional liability and the consequences of NIH suspension—must be thoroughly explained.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed confidential national near-miss system is one of the strongest elements of the draft, but its success depends on separating voluntary learning from punitive enforcement. To protect safety culture, the NIH must define "incident" much more precisely. The reporting trigger must be based on actual or reasonably foreseeable biological risk, distinguishing true exposures and containment failures from minor procedural deviations or basic first aid events.

Furthermore, we urge the NIH to reconsider the mandatory public posting of all final incident reports and standardized IBC minutes. While transparency is important, mandatory public disclosure of lower-level events may discourage candid reporting, encourage defensive classification of incidents, and inadvertently expose proprietary or security-sensitive facility vulnerabilities. A balance must be reached between accessibility of reporting and over publicizing where biohazardous materials are used and located.

6. Other feedback relevant to this resource: Institutions are currently navigating a complex web of federal biosafety regulations. To avoid duplicative risk assessments, the NIH should provide a formal crosswalk aligning this new policy with the USG Policy for Stopping High-Risk Life Sciences Research, the Federal Select Agent Program (FSAP), CDC, OSHA, FDA, USDA, and BMBL guidelines.

Finally, the transition plan will dictate whether implementation is manageable or chaotic. The NIH must explain how existing IBC registrations will be grandfathered, when active protocols require de novo review under the new categories, and what the transition period will be before enforcement of the Biosafety Assurance begins.

RE: Response to Request for Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards - NOT-OD-26-112

To Whom It May Concern:

Executive Summary

We support the NIH's goal of replacing a technology-specific recombinant-DNA framework with a more modern, risk-based biosafety system. The draft contains several promising approaches, particularly tiered review, delegated review of lower-risk activities, experiment-specific containment decisions, and national learning from near misses. However, the policy needs substantially greater clarity regarding scope and definitions, delegated-review competency, clinical nucleic-acid research, incident thresholds and public disclosure, institutional assurances, and coordination with other federal oversight systems. A risk-based policy should reduce unnecessary review while ensuring that scarce biosafety expertise remains focused on the activities capable of causing the greatest harm. Penn State supports the comments submitted by COGR and offers the following:

1. Scope, Definitions, and Applicability

To successfully transition from a recombinant DNA framework to a broader biohazard policy, the NIH must establish clear jurisdictional boundaries. Currently, the draft leans heavily toward human health hazards, leaving the oversight of animal, agricultural, plant, and environmental hazards ambiguous. For example, the rationale for removing genetically modified plants from the main framework is unclear and raises questions about where oversight for agricultural and ecological risks will reside.

Furthermore, foundational definitions require immediate clarification to prevent inconsistent institutional interpretations. The NIH must clearly define what constitutes "genetic modification" (e.g., does it include conventional mutagenesis or passaging?) and provide concrete examples of covered versus exempt activities. Similarly, the definition of

"periodic oversight" must be specified to prevent institutions from building overly burdensome, non-standardized compliance systems. Finally, the NIH must explicitly define institutional applicability, detailing how the policy applies to affiliated hospitals, subcontractors, and projects funded by non-NIH sources at NIH-funded institutions.

2. Clinical Research and Gene Transfer
The reorganization of the Human Gene Transfer (HGT) framework creates significant uncertainty for clinical research. The NIH should provide a formal crosswalk demonstrating how research currently reviewed under HGT provisions maps to the new categories. Specifically, the policy must explicitly address the status of conventional, non-replicating, non-integrating mRNA products (such as mRNA vaccines). Because these products do not neatly fit the new clinical triggers involving shedding, integration, or higher-risk administration, the NIH must clarify whether they require IBC review or are exempt.

3. Review Processes, Competency, and Administrative Burden
We strongly support the introduction of delegated review for lower-risk work and the separation of Risk Group (RG) from Biosafety Level (BSL). However, these flexibilities require clear competency standards. The NIH must define the specific qualifications required for an IBC member to serve as a delegated reviewer and clarify the qualifications required for a Biological Safety Officer (BSO), distinguishing between the administrative assignment of the role and actual technical competency.

Additionally, the NIH must assess the cumulative workload of this "risk-based" system. Requirements for periodic oversight, de novo reviews every three years, expanded scope, and the new Biosafety Assurance could drastically increase administrative burden. Furthermore, the implications of the new Biosafety Assurance—specifically regarding institutional liability and the consequences of NIH suspension—must be thoroughly explained.

4. Fostering a Just Safety Culture: Incident Reporting and Transparency
The proposed confidential national near-miss system is one of the strongest elements of the draft, but its success depends on separating voluntary learning from punitive enforcement. To protect safety culture, the NIH must define "incident" much more precisely. The reporting trigger must be based on actual or reasonably foreseeable biological risk, distinguishing true exposures and containment failures from minor procedural deviations or basic first aid events.

Furthermore, we urge the NIH to reconsider the mandatory public posting of all final incident reports and standardized IBC minutes. While transparency is important, mandatory public disclosure of lower-level events may discourage candid reporting, encourage defensive classification of incidents, and inadvertently expose proprietary or security-sensitive facility vulnerabilities. A balance must be reached between accessibility of reporting and over publicizing where biohazardous materials are used and located.

5. Interagency Coordination and Implementation Strategy
Institutions are currently navigating a complex web of federal biosafety regulations. To avoid duplicative risk assessments, the NIH should provide a formal crosswalk aligning this new policy with the USG Policy for Stopping High-Risk Life Sciences Research, the Federal Select Agent Program (FSAP), CDC, OSHA, FDA, USDA, and BMBL guidelines.

Finally, the transition plan will dictate whether implementation is manageable or chaotic. The NIH must explain how existing IBC registrations will be grandfathered, when active protocols require de novo review under the new categories, and what the transition period will be before enforcement of the Biosafety Assurance begins.

Conclusion
We commend the NIH for modernizing this framework and preserving vital flexibilities for local risk assessment. By clarifying definitions, protecting safety culture from punitive public disclosure, and providing clear transitional guidance, the NIH can ensure this policy achieves its goal: concentrating expert attention on significant biological risks rather than expanding administrative compliance structures.

Sincerely,

Sepideh Sefidvash-Hockley

244. Jonathan Fidler

I am responding: On behalf of myself

Name: Jonathan Fidler

Name of Organization: Atlanta VA Health Care System

Type of Organization: Government Agency

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Antibiotic resistance

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I strongly encourage NIH to expand upon the list of defined terms in the draft policy. Many mission-critical terms remain undefined. Others have definitions that, in turn, refer to undefined terms.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Whereas I genuinely appreciate the effort to introduce tiered oversight, I strongly encourage NIH to reconsider the use of the terminology "delegated review" as opposed to "designated member review" to harmonize with IACUC and other oversight bodies. Absent of an extremely compelling reason to use differing terminology for a very similar process, this is bound to cause confusion even among subject matter experts. "Designated Member Review" is a much more appropriate term for this process.

3. Continued utility of Risk Groups: Whereas the distinction between RG and BSL can be difficult to explain to those outside of the Biosafety and Biosecurity fields, I do feel it is important to assign risk to agents and containment policy to procedures. I approve of the continued use of Risk Groups.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Guidance will be necessary on reporting of accidents and reporting of meeting minutes if NIH is to expect voluntary compliance. Absent of clear and robust guidance on what may be redacted and what must be included, non-NIH funded institutions may simply feel it is in their best interests to not comply with this policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Requiring standardized templates for both Incident Reporting and Meeting Minutes that will almost certainly differ from those already established at institutions represents significant duplication of administrative effort. I strongly encourage the NIH to reconsider making these forms mandatory, and instead make them optional with included guidelines on what elements are required in Incident Reports and Meeting Minutes should an institution use a different format.

6. Other feedback relevant to this resource: The proposed timeline for implementation is, frankly, not nearly enough time for institutions to pivot their internal policies toward congruency with these

revisions, given how extensively the policy has been revised, as well as legal ramifications and the potential need to hire subject matter experts. One calendar year from roll-out to enforcement will be a bare minimum timeline. Anything less is likely to result in policy noncompliance due to rushed implementation.

RE: Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

To Whom It May Concern:

I am submitting this comment in response to the National Institutes of Health (NIH) effort to modernize and strengthen the oversight of biosafety. The views and opinions expressed here are my own and do not necessarily reflect the official position of my employer.

In my role as the Select Agent Responsible Official at the University of Wisconsin – Madison, my work to continue to effectively manage a compliant, safe, and secure Select Agent Program will be directly impacted by a new NIH policy on biosafety. I support the comments and recommendations submitted by the Office of the Vice Chancellor for Research (OVCR) and the Institutional Biosafety Committee (IBC) at the University of Wisconsin – Madison as well as comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA) regarding this effort. Collectively these comments appropriately reflect the needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs. Additionally, ABSA International — The Association for Biosafety and Biosecurity has provided extensive comments and recommendations from the broader community of biosafety and biosecurity professions that need to be addressed to ensure that this new policy can be implemented effectively by all organizations subject to the new policy.

Several key areas that must be addressed include:

- **Scope and Oversight:** Clarifying which research activities fall under the policy and explicitly addressing when another federal agency oversight substitutes for NIH or IBC oversight under this policy.
- **Institutional Responsibilities:** Ensuring that Institutional Biosafety Committees (IBCs) and biosafety professionals have appropriate authority and institutional support to fulfill expanded responsibilities.
- **Transparency and Incident Reporting:** Balancing public transparency with protection of sensitive research information, individual privacy, and a strong safety culture that encourages reporting of incidents and near misses.
- **Implementation Timeline:** Increasing the proposed six-month effective date to a minimum 12-month or preferably a 24-month phased transition period, accompanied by clear guidance, standardized tools, training, and appropriate resources.

Given the number of unresolved questions and the potential impacts to ongoing research programs, I respectfully request that NIH release revised drafts for an additional period of public review and comment before issuing a finalized policy.

Thank you for the opportunity to comment.

Sincerely,

Christina Pier, MS, RBP (ABSA)
Select Agent Responsible Official
University of Wisconsin - Madison

246. National Institutes of Health, Division of Intramural Research, Animal Research Advisory Committee

I am responding: On behalf of an organization

Name: Dr Mark Hoon

Name of Organization: National Institutes of Health, Division of Intramural Research, Animal Research Advisory Committee

Type of Organization: Government Agency

Role: Government Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): All areas of Biological Research with a primary focus on Biosafety in animal research.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Animal Research Advisory Committee (ARAC) supports NIH's objective of maintaining strong, risk-based biosafety oversight and appreciates the effort to modernize the existing NIH Guidelines. We encourage NIH to ensure that the final policy adjusts oversight of biosafety aspects of animal research to demonstrable biosafety risk while avoiding unnecessary duplication with established animal-care, veterinary, occupational-health, and institutional compliance systems. We offer comments regarding animal-related research, with particular attention to registration, tracking, incident reporting, and administrative burden (see attached document).

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): No Comment.

3. Continued utility of Risk Groups: The current NIH Biosafety Guidelines distinguish between higher-risk animal experiments, BL1 transgenic rodent activities requiring notice, and specified BL1 breeding and purchase/transfer activities that are exempt. The draft Policy suggests that pre-initiation approval for research with transgenic organisms at BSL/ABSL-1 may be required. NIH should consider retaining exemptions or notification-based pathways for well-characterized, low-risk animal activities where the genetic modification does not create a meaningful increase in biosafety risk. In addition, NIH should consider permitting registrations of types of genetic modification of animals rather than requiring a registration for each unique genetic modification. Furthermore, should NIH not want to exempt all BSL/ABSL1 transgenic work from preapproval, we would encourage consideration of whether stratifying risk by the type of genetic modification and by the species to be modified is appropriate, e.g., USDA Animal Welfare Act (covered species) versus not covered species (conventional rodents). We support the proposal for delegated review as a useful streamlining mechanism, but it does not by itself eliminate the extremely burdensome administrative requirement for submission, approval, documentation, and committee reporting (even when streamlined through delegated review) if now exempt activities need to be individually reviewed.

The draft limits IBC approval to three years and requires de novo registration submission and review at the end of that period. For stable, low-risk animal studies and breeding colonies, NIH should consider administrative renewal, continuing review based on changed risk, or a longer approval period when there has been no material change in the biosafety assessment. NIH should also define the types of changes that require prior IBC amendment so routine animal-management changes or minor changes of methods for generation of transgenic animals do not inadvertently trigger unnecessary biosafety review. Provide guidance on amendment and renewal thresholds that would preserve safety while avoiding review of changes with no material biosafety impact.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comment.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft identifies bites, scratches, escapes, and improper disposition involving research at BSL/ABSL-1 or BSL/ABSL-2 as incidents that must be reported to and addressed by the IBC. Many such events are appropriately managed through established animal-care, veterinary, occupational-health, or facility procedures and may have no meaningful biosafety consequence. Indeed, the draft states “Minor spills of low-risk agents, that do not involve a breach of containment and that were properly cleaned and decontaminated, generally do not need to be reported.” which would seem to be equivalent to most of the animal incidents that the draft says should be reported suggesting this requirement would not be appropriate in terms of calibration of risk. Therefore, NIH should consider limiting mandatory IBC reporting to events involving an actual or reasonably possible exposure to a covered biohazard, loss of containment, environmental release, or other material biosafety consequence, while allowing institutions to define pathways for routine events.
The final policy should distinguish between incidents that warrant federal/public transparency and routine lower-risk events that are appropriately documented and reviewed internally. For animal facilities, incident reports may contain operational or facility information requiring careful redaction which would require duplicative burdensome additional documentation. NIH should consider limiting mandatory public posting to NIH-reportable incidents or permitting aggregated and de-identified reporting for lower-risk incidents. At minimum, NIH should issue clear standards for permissible redaction and for protecting security-sensitive, proprietary, personal, and animal-facility information. The final policy should state that institutions may rely on or cross-reference existing IACUC, veterinary, vivarium, occupational-health, select-agent, and other applicable records when those records contain information needed for the biosafety determination. NIH should clarify that the policy does not require a parallel animal inventory, separate animal-level tracking system, or duplicate entry of information already maintained in an existing institutional system unless a distinct biosafety purpose requires it.

6. Other feedback relevant to this resource: NIH should provide feedback identifying the minimum biosafety information required for animal protocols and distinguishing IBC responsibilities from IACUC, veterinary, and animal-facility responsibilities. Where an existing institutional review has already addressed an issue relevant to biosafety, the IBC should be permitted to rely on that review or incorporate it by reference rather than recreate it.

Uploaded File: ARAC-response-to-Biosafety-Policy-Final.docx

The Animal Research Advisory Committee (ARAC) supports NIH's objective of maintaining strong, risk-based biosafety oversight and appreciates the effort to modernize the existing NIH Guidelines. We encourage NIH to ensure that the final policy adjusts oversight of biosafety aspects of animal research to demonstrable biosafety risk while avoiding unnecessary duplication with established animal-care, veterinary, occupational-health, and institutional compliance systems. We offer the following comments regarding animal-related research, with particular attention to registration, tracking, incident reporting, and administrative burden.

1. Preserve proportionate treatment of low-risk transgenic animal activities.

The current NIH Biosafety Guidelines distinguish between higher-risk animal experiments, BL1 transgenic rodent activities requiring notice, and specified BL1 breeding and purchase/transfer activities that are exempt. The draft Policy suggests that pre-initiation approval for research with transgenic organisms at BSL/ABSL-1 may be required. NIH should consider retaining exemptions or notification-based pathways for well-characterized, low-risk animal activities where the genetic modification does not create a meaningful increase in biosafety risk. In addition, NIH should consider permitting registrations of types of genetic modification of animals rather than requiring a registration for each unique genetic modification. Furthermore, should NIH not want to exempt all BSL/ABSL1 transgenic work from preapproval, we would encourage consideration of whether stratifying risk by the type of genetic modification and by the species to be modified is appropriate, e.g., USDA Animal Welfare Act (covered species) versus not covered species (conventional rodents). We support the proposal for delegated review as a useful streamlining mechanism, but it does not *by itself* eliminate the extremely burdensome administrative requirement for submission, approval, documentation, and committee reporting (even when streamlined through delegated review) if now exempt activities need to be individually reviewed.

2. Provide a risk-based alternative to mandatory de novo review every three years.

The draft limits IBC approval to three years and requires *de novo* registration submission and review at the end of that period. For stable, low-risk animal studies and breeding colonies, NIH should consider administrative renewal, continuing review based on changed risk, or a longer approval period when there has been no material change in the biosafety assessment. NIH should also define the types of changes that require prior IBC amendment so routine animal-management changes or minor changes of methods for generation of transgenic animals do not inadvertently trigger unnecessary biosafety review. Provide guidance on amendment and renewal thresholds that would preserve safety while avoiding review of changes with no material biosafety impact.

3. Establish an explicit non-duplication principle for animal records and tracking.

The final policy should state that institutions may rely on or cross-reference existing IACUC, veterinary, vivarium, occupational-health, select-agent, and other applicable records when those records contain information needed for the biosafety determination. NIH should clarify that the policy does not require a parallel animal inventory, separate animal-level tracking system, or duplicate entry of information already maintained in an existing institutional system unless a distinct biosafety purpose requires it.

4. Clarify the division of responsibilities between IBC and animal oversight programs.

NIH should provide feedback identifying the minimum biosafety information required for animal protocols and distinguishing IBC responsibilities from IACUC, veterinary, and animal-facility responsibilities. Where an existing institutional review has already addressed an issue relevant to biosafety, the IBC should be permitted to rely on that review or incorporate it by reference rather than recreate it.

5. Apply a materiality threshold to lower-risk animal incident reporting.

The draft identifies bites, scratches, escapes, and improper disposition involving research at BSL/ABSL-1 or BSL/ABSL-2 as incidents that must be reported to and addressed by the IBC. Many such events are appropriately managed through established animal-care, veterinary, occupational-health, or facility procedures and may have no meaningful biosafety consequence. Indeed, the draft states "Minor spills of low-risk agents, that do not involve a breach of containment and that were properly cleaned and decontaminated, generally do not need to be reported." which would seem to be equivalent to most of the animal incidents that the draft says should be reported suggesting this requirement would not be appropriate in terms of calibration of risk. Therefore, NIH should consider limiting mandatory IBC reporting to events involving an actual or reasonably possible exposure to a covered biohazard, loss of containment, environmental release, or other material biosafety consequence, while allowing institutions to define pathways for routine events.

6. Reconsider mandatory public posting of lower-risk animal incident reports.

The final policy should distinguish between incidents that warrant federal/public transparency and routine lower-risk events that are appropriately documented and reviewed internally. For animal facilities, incident reports may contain operational or facility information requiring careful redaction which would require duplicative burdensome additional documentation. NIH should consider limiting mandatory public posting to NIH-reportable incidents or permitting aggregated and de-identified reporting for lower-risk incidents. At minimum, NIH should issue clear standards for permissible redaction and for protecting security-sensitive, proprietary, personal, and animal-facility information.

Specific Recommendations for the Final Policy

- Preserve or create risk-based exemptions/notification pathways for low-risk transgenic animal breeding, acquisition, transfer, and maintenance where no material biosafety risk is introduced.
- Permit streamlined renewal rather than mandatory de novo review for stable low-risk animal research when the biosafety assessment has not materially changed.
- Define amendment thresholds with examples specific to animal research, including changes in strain, breeding, housing, procedures, vectors, agents, and containment.
- Adopt a single-record/cross-reference principle so existing IACUC, veterinary, vivarium, occupational-health, and other records may satisfy overlapping documentation requirements.
- Clarify that the policy does not independently require a universal animal-level inventory or duplicative animal tracking system.
- Limit mandatory IBC review of routine animal incidents to events with a material biosafety nexus, or allow institutions to use risk-based triage procedures.
- Limit public posting of lower-risk incidents or permit aggregated/de-identified disclosure, with clear redaction standards for sensitive facility and personnel information.
- Provide an IBC-IACUC coordination crosswalk and model workflows before the effective date.
- Provide adequate implementation time, standardized definitions, and burden estimates that specifically account for high-volume animal research programs.

ARAC supports a streamlined modern biosafety framework that directs oversight and institutional resources toward activities presenting meaningful risk. For animal research, the final policy should preserve proportionate pathways for low-risk activities, prevent duplicative registration and tracking, establish clear boundaries between IBC and animal-care oversight, and focus incident review and public reporting on events with a meaningful biosafety nexus. These clarifications would strengthen implementation while allowing institutional biosafety programs to concentrate expertise and resources where they provide the greatest safety benefit.

Submission Portal:	Submitted via NIH OSP Electronic Comment Portal
Subject / Notice:	Formal Public Comments and Recommendations on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice Number: NOT-OD-26-112)

ABSA International, the Association for Biosafety and Biosecurity, is a nonprofit professional association representing biosafety and biosecurity professionals in the United States and internationally. Our membership spans academic and research institutions, government laboratories, biotechnology companies, healthcare organizations, public health agencies, and consulting practices. Members bring scientific, technical, operational, and regulatory expertise across diverse biological research and laboratory settings.

ABSA's comments reflect the practical experience of professionals responsible for translating biosafety policy into daily practice. Our members conduct risk assessments, support Institutional Biosafety Committees (IBCs), develop training and containment practices, investigate incidents, and advise institutions on compliance. They understand how policy requirements affect laboratory safety, reporting culture, institutional resources, and the conduct of research.

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public

confidence in NIH-supported science. ABSA supports NIH's efforts to strengthen biosafety oversight. We offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

***Topic to Address**: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:

    a. the nature and stability of the genomic modification;

    b. whether the modification is heritable and the potential for transmission through breeding;

    c. effects on animal health, phenotype, host range, susceptibility, or disease;

    d. potential entry into breeding or food-production systems;

    e. potential environmental release or interaction with non-research animal populations;

    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and

    g. applicable federal, state, or other regulatory oversight.

2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

    Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

ABSA International believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, ABSA International requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, ABSA International welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. ABSA International does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. ABSA International recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, ABSA International recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with ABSA's earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. ABSA International recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, ABSA International kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. ABSA International encourages NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While ABSA supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: ABSA recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

248. Washington University in St. Louis

I am responding: On behalf of an organization

Name:

Name of Organization: Washington University in St. Louis

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Executive Summary

Washington University in St. Louis (WashU) supports NIH's goal of establishing a comprehensive and adaptable biosafety framework that protects research personnel, the public, and the environment while responding to evolving scientific risks. The draft policy provides an important opportunity to strengthen consistency in biosafety oversight across institutions. WashU's principal recommendations are intended to ensure that the final framework remains risk-based, scientifically workable, and feasible to implement without diverting oversight resources from research that presents the greatest biosafety risk.

Across the six areas addressed in this RFI, several themes recur. First, key definitions and scope provisions should clearly distinguish novel, higher-risk, or higher-uncertainty research from routine, well-characterized activities. Second, the level and timing of IBC oversight should remain proportional to actual risk, with appropriate use of exemptions, notification-based pathways, and delegated or expedited review for lower-risk research. Third, Risk Groups should remain a useful baseline for risk assessment without functioning as a fixed proxy for containment when the characteristics of a modified agent or experimental context alter risk.

WashU also recommends that compliance, incident-reporting, and public-transparency requirements reinforce a strong safety culture. Accountability is essential, but enforcement should distinguish significant biosafety failures from administrative deficiencies, and reporting requirements should preserve incentives for candid reporting of near misses and lower-risk events. Finally, successful implementation will require clear transition rules, practical guidance and decision tools, sufficient federal review capacity, and adequate time for institutions to modify systems, training, workflows, and existing protocol portfolios.

These recommendations share a common objective: focusing biosafety oversight and institutional resources where they provide the greatest safety benefit while preserving efficient pathways for well-characterized, lower-risk research.

1. Appropriateness of the scope of the new policy, including the definition of biohazard for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

Discussion: Several elements of the proposed scope are sufficiently broad or undefined that they could

substantially expand IBC oversight of routine, well-characterized, lower-risk research without a corresponding increase in biosafety benefit. Greater specificity is needed to ensure that the scope is calibrated to actual risk and can be implemented consistently across institutions.

The definition of a biological agent as an agent that "causes human disease" would benefit from clarification regarding the population on which that determination is based. Elsewhere in the draft policy, Risk Group classifications are described in relation to effects in a healthy adult, suggesting a potentially narrower standard than the general definition of biological agent. NIH should clarify the intended relationship between these provisions so institutions can determine consistently which agents fall within scope.

The definition of a "novel agent or organism" also requires refinement. The draft identifies chimeras as an example of a novel agent or organism but does not define "chimera." As written, that terminology could encompass common viral vectors and recombinant constructs that are well characterized and routinely used under established biosafety practices. During institutional review, investigators noted that many routinely used gene-therapy and viral-vector systems could technically be described as chimeric. The final policy should distinguish novel or higher-uncertainty constructs from routine recombinant or chimeric systems whose risks are already well understood. NIH should also clarify whether "novel" refers to a truly newly identified biological agent or encompasses newly collected variants or isolates of an otherwise well-characterized agent. Without that distinction, routine environmental or clinical sampling, including isolation of new variants of common pathogens for sequencing or characterization, could be interpreted inconsistently.

The term "wild type" also warrants clarification. In virology, a laboratory reference strain may have undergone passage or adaptation and may not be identical to a primary or clinical isolate. In many fields, "wild type" is also used simply to denote the parental strain from which laboratory clones or mutants are derived, and that parental strain may itself be a long-established, laboratory-adapted isolate. In addition, RNA viruses exist as quasi-species represented by a consensus sequence rather than a single fixed sequence, and mutations introduced experimentally may also occur naturally. Without a scientifically workable definition, institutions and federal reviewers could apply "wild type" inconsistently when determining whether research falls within scope or requires additional review.

Additional clarification is needed regarding research with primary cells that may contain adventitious agents. A broad interpretation could extend IBC review to routine processing of human clinical samples even when the activity is already managed through established bloodborne-pathogen protections. Similarly, the provision covering clinical products capable of shedding, replicating, or integrating could be interpreted to extend beyond genetically modified or vector-based products to other cell-based interventions. NIH should clarify the intended boundaries of these provisions so that the policy does not inadvertently duplicate existing safety oversight or bring activities outside the intended biosafety risk framework into IBC review.

WashU Operational Example: At WashU, some ambulatory and clinical research settings process primary human samples for activities such as aliquoting, preparation for shipping, or clinical trial testing. These activities are currently managed through bloodborne-pathogen training, appropriate PPE, and related safety requirements rather than full IBC review when no known or suspected infectious agent is involved. The draft policy language regarding primary cells that may contain adventitious agents creates uncertainty as to whether these routine activities would newly require IBC protocols, potentially creating duplicative oversight without a clear additional biosafety benefit.

Recommendation: NIH should revise the final policy and accompanying guidance to:

• define key scope terms, including “biological agent,” “novel agent or organism,” “chimera,” and “wild type,” using scientifically meaningful criteria and examples that distinguish higher-risk or higher-uncertainty research from routine, well-characterized activities;
• clarify when primary human cells and clinical sample processing fall within IBC oversight and when existing bloodborne-pathogen or other established safety programs are sufficient;
• clarify the intended scope of the clinical research provisions for products capable of shedding, replicating, or integrating, including their applicability to non-vector cell-based products; and
• provide clear exclusions or examples to prevent routine, low-risk research from being unintentionally captured by the expanded definition of biohazard.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Discussion: WashU supports a tiered oversight framework in which the level of review is calibrated to the biosafety risk and uncertainty associated with the proposed research. The draft policy appropriately recognizes that not all research involving biohazards warrants the same level of oversight. However, several of the proposed categories appear likely to move substantial volumes of routine, lower-risk research from currently streamlined institutional pathways into delegated or full IBC review. Without additional refinement, the framework could increase administrative burden and delay research without a commensurate improvement in biosafety.

The distinction among research requiring NIH and IBC approval, full IBC review, and delegated review is particularly important. Under the proposed framework, initial submissions involving genetically modified cells, viruses, or organisms generally require IBC review and approval before initiation, whereas only specified lower-risk activities may be delegated to an individual or subgroup of IBC members. The delegated-review list includes certain activities such as genetically modified Risk Group 1 agents, BSL-1/ABSL-1 transgenic organisms, replication-incompetent non-integrating vectors expressing low-risk transgenes, and well-characterized cell lines. Although this is a useful starting point, the categories should be sufficiently broad and clearly defined to preserve efficient review of well-characterized, low-risk research.

The need for proportionality is especially apparent for replication-defective or single-cycle agents, routine cloning systems, well-characterized vectors, and other research in which the biological characteristics substantially limit the potential for propagation or harm. During WashU’s review, investigators and biosafety personnel repeatedly emphasized that such work should remain eligible for appropriately streamlined pathways, including exemption, notification-based review, or expedited or delegated review, as warranted by risk, rather than requiring more resource-intensive committee processes.

Risk assessment should also consider the biological context in which a gene or factor is being studied. A factor associated with virulence in its native organism may not create the same hazard when cloned into a non-pathogenic laboratory strain solely for nucleic-acid propagation or protein production. Requiring heightened review based on the label “virulence factor” alone, without considering expression, host context, and experimental use, could unnecessarily delay routine research without improving safety.

The change in timing of review is also significant. Under current WashU practices, some well-characterized, low-risk activities are exempt from formal NIH Guidelines review or may proceed concurrently with institutional notification. Under the proposed framework, these activities would instead require documented prior approval through either delegated or full IBC review. Requiring prior approval for activities whose underlying biosafety risk has not changed may create avoidable delays without providing a corresponding safety benefit.

The proposed treatment of emerging, novel, or zoonotic agents also raises a different tiering concern. The draft policy requires NIH and IBC approval before research may begin when a Risk Group classification or recommended minimum containment level is not available in the BMBL. This approach appropriately recognizes the uncertainty associated with newly identified agents, but it could also create a significant delay in pathogen discovery and public health response if federal review is not sufficiently rapid. During an outbreak, the ability to isolate and characterize a newly identified agent is time-sensitive. A tiered framework should therefore account not only for risk, but also for the consequences of delaying research necessary to characterize that risk.

WashU Operational Example: Under current WashU practices, some well-characterized activities, including certain AAV and ecotropic retroviral vector work, can be handled through streamlined institutional pathways, including exemption or notification-based processes, rather than requiring prior committee approval. The draft framework would require documented prior approval through the IBC or an authorized delegated-review mechanism before such work begins. Similarly, BSL-1/ABSL-1 transgenic animal activities that currently may not require the same level of IBC review would become subject to delegated review under the proposed policy. These changes could substantially increase formal reviewer involvement and introduce additional approval steps even when the underlying risk is low and well understood. This may delay experimental progress and will divert review time from higher-risk work or novel experimental procedures where the IBC's time and expertise will be better spent.

Recommendation: NIH should refine the tiered oversight framework to:

• preserve appropriate exemptions, notification-based pathways, and delegated or expedited review mechanisms for well-characterized, lower-risk research, including clearly defined categories of replication-defective, single-cycle, and other low-risk vector systems;

• provide clear definitions and examples for terms and categories such as "certain vectors," "well-characterized cell lines," and "virulence factors," including how biological context should inform eligibility for delegated review, so that institutions can apply the framework consistently;

• allow institutional IBCs sufficient discretion to determine, based on a documented risk assessment, when a low-risk activity may remain exempt, proceed through notification, or receive expedited or delegated review;

• clarify that de novo review at renewal does not automatically require full committee review and may be completed through delegated review when the research continues to meet appropriate lower-risk criteria;

• clarify the review expectations for BSL-1/ABSL-1 transgenic organisms and other activities that may be newly brought into formal IBC review;

• establish a rapid, predictable federal review process for emerging, novel, or zoonotic agents, particularly when timely research is important to an active public health response; and

• evaluate the cumulative administrative burden created by shifting currently streamlined activities into formal review and ensure that additional oversight is proportionate to the biosafety benefit achieved.

3. Continued utility of Risk Groups: Discussion: WashU supports retaining Risk Groups as a useful starting point for biosafety risk assessment, but RG classification should not function as the sole determinant of the containment level required for a particular experiment. The draft policy appropriately recognizes that RGs and BSLs are related but distinct concepts: RGs describe characteristics of the biological agent, whereas the appropriate BSL depends on the specific research activities, manipulations, genetic modifications, routes of exposure, and available mitigation measures.

This distinction is particularly important when agents are genetically modified. The risk associated with a

modified agent may be greater or lower than that of its parent. Genetic modifications can alter pathogenicity, transmissibility, host range, tissue tropism, or other characteristics that increase risk, but they can also attenuate an agent or render it replication defective. The draft policy itself acknowledges these possibilities and appropriately calls for consideration of both the underlying agent and the effect of the modification.

For this reason, WashU recommends that RG classification remain a baseline input to risk assessment rather than a fixed proxy for laboratory containment. The final determination of BSL should reflect the characteristics of the modified agent and the manner in which it will be used. A framework that relies too heavily on parent-agent RG classification could result in containment requirements that do not reflect the actual risk of a particular construct or experiment.

The usefulness of either RG or BSL classifications also depends on the availability of current, authoritative federal guidance. During WashU's review, investigators and biosafety personnel noted that new and emerging agents may not be reflected promptly in existing reference materials. The draft policy's proposal to publish containment determinations that can be relied upon across institutions could improve consistency and reduce duplicative requests, provided those determinations are updated frequently and made available in a timely manner.

Illustrative Example: A genetically modified agent derived from an RG3 parent may be attenuated or replication-defective in a manner that materially reduces its biological risk. In such a case, automatically equating the parent RG with BSL-3 containment may impose a level of containment that is not supported by the characteristics of the modified construct. Conversely, a modification to a lower-risk agent that increases transmissibility, host range, or pathogenicity could justify higher containment.

These examples illustrate why RG classification is most useful as the starting point for a structured risk assessment, with the final containment determination based on the properties of the specific agent and the proposed experimental manipulations.

Recommendation: NIH should:

• retain Risk Groups as a baseline component of biosafety risk assessment, while making clear that RG classification does not by itself determine the appropriate BSL for a specific experiment;

• preserve a risk-assessment framework that accounts for both risk-increasing and risk-decreasing effects of genetic modification;

• provide clear criteria and examples for circumstances in which the appropriate BSL may reasonably differ from the RG classification of the parent agent;

• maintain a centralized, publicly accessible resource containing NIH-approved containment determinations that institutions may rely upon without submitting duplicative requests; and

• establish a process for frequent and timely updates to RG classifications, BSL recommendations, and containment determinations as new agents and scientific information emerge.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Discussion: WashU supports meaningful accountability for institutional biosafety programs and agrees that effective compliance mechanisms are necessary to protect research personnel, the public, and the environment. At the same time, enforcement should be proportionate to the nature, severity, and consequences of the noncompliance. The draft policy authorizes a range of enforcement actions, including additional terms and conditions, suspension or termination of funding, and potential effects on future funding decisions. Given the breadth of the proposed policy and the number of activities that may newly fall within its scope, NIH should ensure that enforcement distinguishes significant safety failures from inadvertent or administrative noncompliance

that may arise during implementation of a substantially expanded framework. Since the draft policy describes a broad range of enforcement actions, NIH should provide clear guidance or examples of the criteria under which each enforcement action could be taken.

The proposed Biosafety Assurance mechanism may provide a useful means of establishing institutional accountability, but additional guidance is needed regarding the expected content, review process, and standards for NIH approval. The draft policy requires institutions to document lines of authority, publicly available biosafety procedures, IBC information, training, incident reports, and other elements of the institutional program. Greater clarity regarding how NIH will evaluate these Assurances and the required supporting documentation would help institutions understand whether the process is intended primarily as an organizational attestation, a programmatic review, or a more formal assessment of institutional biosafety systems.

Compliance mechanisms should also reinforce, rather than undermine, a strong safety-reporting culture. The draft policy appropriately encourages confidential voluntary reporting of near misses and procedural issues to the National Biosafety Data and Safety Analysis Center and states that NIH will not use voluntarily submitted information for enforcement or funding action when specified conditions are met. This non-punitive framework creates a protected learning system that supports continuous improvement and should be preserved. At the same time, the broader public-reporting requirements elsewhere in the policy could create tension with that goal if researchers become reluctant to report minor events or near misses because of concerns about public disclosure.

For research and institutions not subject to the policy, voluntary adoption may be more effectively encouraged through clear, practical, and scalable standards, training resources, shared best practices, and demonstrated biosafety benefit than through mechanisms that resemble indirect enforcement. A policy designed to serve as a model framework should therefore be sufficiently clear, risk-proportionate, and practical so that institutions can adopt its principles without assuming unnecessary administrative burden.

Illustrative Example: A newly expanded policy may result in institutions identifying activities that were previously handled through streamlined or alternative safety processes but that now require formal IBC review or documentation. Failure to complete a newly required administrative step should not automatically be treated in the same manner as conduct that creates a significant biosafety risk, such as knowingly conducting high-risk research without required approval or failing to respond appropriately to a serious containment event.

Similarly, a researcher who voluntarily reports a near miss provides information that may help prevent a future incident. Compliance structures should encourage that behavior rather than disincentivize the reporting of low-level events that can provide important lessons for institutional safety programs.

Recommendation: NIH should:

• apply compliance and enforcement mechanisms proportionately, taking into account the severity, duration, intent, and actual or potential biosafety consequences of noncompliance;

• distinguish significant safety violations from administrative or procedural deficiencies, particularly during implementation of the new policy;

• provide clear guidance on the Biosafety Assurance process, including the standards NIH will use to review and approve institutional Assurances;

• preserve strong protections for voluntary near miss and safety-learning reports so that institutions and investigators are encouraged to identify and address problems before they result in harm;

• align public-reporting and enforcement requirements with the goal of maintaining a candid

institutional safety culture; and
• encourage voluntary adoption by non-covered institutions through practical guidance, training, model procedures, and other implementation resources that demonstrate the value of the framework.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Discussion: WashU supports transparent biosafety oversight and consistent documentation of significant incidents. Use of the proposed IBC meeting minute template appears generally workable and the requirement to publicly post IBC meeting minutes is consistent with WashU's existing practices. Of significant concern, however, is the proposed incident-reporting framework, particularly the requirement to publicly post incident reports and the relationship between reportable incidents, lower-risk events reviewed by the IBC, and broader institutional safety-learning activities.
The draft policy distinguishes incidents that require notification to NIH from certain lower-risk incidents that must be reported to and reviewed by the IBC but do not require NIH notification. It also requires institutions to post incident reports on a public-facing website after institutional or NIH review. Greater clarity is needed regarding exactly which reports must be publicly posted and the level of information that must be included.
WashU is particularly concerned about the potential negative effect of mandatory public disclosure on a strong safety-reporting culture. Effective biosafety programs depend on investigators and laboratory personnel reporting not only serious events, but also minor incidents and near misses that provide opportunities for learning and prevention. If lower-level events automatically require public disclosure, researchers may become less willing to report them candidly. This could undermine the preventive purpose of institutional incident review.
The incident-reporting template should therefore distinguish transparency related to significant biosafety events from institutional systems designed for continuous improvement. Publicly posted information should also be understandable in context. Highly technical reports may be difficult for a general audience to interpret and could create misunderstanding without necessarily advancing biosafety. NIH should consider whether a contextualized or lay summary could satisfy public-transparency objectives while the detailed technical report remains available to NIH and appropriate institutional oversight bodies.
Clear guidance on allowable redactions will also be important. Incident reports and meeting minutes may include information about research protocols, animal models, facilities, or other details for which public disclosure could raise privacy, security, legal, intellectual property, or research-sensitivity concerns. Even when investigator names and specific locations are omitted, combinations of scientific, protocol, or facility information may make it possible to infer the laboratory or investigator involved. The final templates should provide consistent standards for what institutions may redact, summarize, or otherwise limit while still meeting NIH's transparency expectations.
An alternative approach would be for NIH to provide public transparency through a centralized, nationally aggregated reporting system rather than requiring institutions to post detailed incident reports locally. Aggregated reporting by incident risk tier, containment level, or other non-identifying characteristics could support transparency and national biosafety learning while reducing the likelihood that technical details can be traced back to individual investigators or laboratories.
WashU Operational Example: WashU currently encourages broad internal discussion of laboratory incidents so that the IBC and Environmental Health and Safety personnel can identify trends, share lessons learned, and improve safety practices. This can include minor laboratory events that may not ultimately constitute an NIH-reportable biosafety incident. The value of this approach is that relatively

minor events can identify weaknesses in procedures or equipment before a more consequential event occurs.
Over the past 12 months, WashU submitted 12 reportable incidents to NIH Office of Science Policy. Based on recent institutional experience, if all lower-risk incidents were reportable under the proposed framework, WashU estimates approximately 12 additional reportable incidents annually. Although an additional incident report per month would be operationally manageable, the requirement to publicly disclose these lower-risk incidents could discourage candid reporting without providing a commensurate biosafety benefit.
Consequently, the WashU IBC could expect to see a reduction in what is formally brought before the IBC, limiting opportunities for important safety-learning discussions and inadvertently weakening an existing mechanism for preventative learning.
WashU also currently redacts certain animal-related details from publicly available IBC minutes to avoid inadvertently identifying sensitive research activities. Clear federal standards regarding permissible redactions would help institutions maintain appropriate transparency without creating unintended disclosure risks.
Recommendation: NIH should:
• create policy requirements that clearly distinguish between incidents requiring NIH reporting, lower-risk incidents requiring IBC review, and voluntary institutional near miss or safety-learning reports;
• specify which categories of incident reports must be publicly posted and whether all lower-risk incidents reviewed by an IBC are intended to trigger public disclosure;
• preserve the ability of institutions to maintain broader internal incident and near miss reporting systems without automatically requiring conversion of those reports into publicly posted records;
• provide clear and consistent standards for allowable redactions and summarization in both incident reports and IBC meeting minutes, including information related to research protocols, animal models, facilities, personnel, privacy, security, and other details that could inadvertently identify sensitive research activities;
• consider a centralized, nationally aggregated public reporting approach that provides meaningful information about biosafety incidents and trends without requiring publication of locally identifiable technical details;
• consider permitting a contextualized or lay summary for public posting while detailed technical incident information is provided to NIH and retained by institutional oversight programs; and
• ensure that the meeting minute and incident-reporting templates capture information necessary for accountability without requiring duplicative documentation or discouraging candid safety reporting.

6. Other feedback relevant to this resource: Discussion: WashU agrees that detailed implementation resources will be essential to successful adoption of the proposed policy. The draft policy would significantly change the scope of research subject to biosafety oversight, the categories and timing of IBC review, institutional assurance requirements, protocol approval periods, public-posting obligations, and federal review processes. NIH proposes an effective date six months after publication of the final policy and would apply the policy to existing awards and ongoing research as of that date. Institutions will therefore need sufficient guidance well in advance of implementation to revise policies, information systems, training materials, IBC workflows, public-facing websites, and protocol-review processes. Transition guidance is particularly important for research already approved when the policy becomes effective. WashU currently operates on a five-year IBC approval cycle, whereas the draft policy limits IBC approvals to three years and requires a de novo registration submission and review at renewal. NIH

should clarify whether existing institutional approvals may remain in effect until their currently scheduled expiration dates and transition to the new framework at their current renewal date, or whether they must be converted or re-reviewed when the policy becomes effective. NIH should also clarify whether the required de novo review at renewal may be completed through delegated review when warranted by risk, or whether renewal automatically requires full committee review. This distinction has substantial implications for institutional feasibility and committee capacity. Similar clarity is needed for previously reviewed agents and constructs, including previously deselected or otherwise federally characterized strains, so that institutions do not repeat reviews solely because the policy framework has changed. Requiring broad re-review within the six-month implementation period could create a substantial concentrated workload without a corresponding biosafety benefit.

Additional guidance is also needed on the proposed Biosafety Assurance. The draft describes the Assurance as documentation submitted through the Authorized Organizational Representative and approved by NIH for up to four years, but the process and approval criteria are not fully described. NIH should clarify whether the Assurance is intended primarily as an institutional attestation or a more substantive programmatic review; what documentation NIH will evaluate; the respective responsibilities of the AOR, IBC, Biological Safety Officer, and other institutional units; the renewal process; and any pre-award coordination expected between institutional signing officials and biosafety programs.

The requirement for periodic review of approved research also warrants implementation guidance. NIH should clarify whether existing institutional laboratory-inspection or Environmental Health and Safety audit processes may satisfy this requirement when appropriately designed, or whether the policy contemplates a separate IBC post-approval monitoring program.

Guidance is similarly needed regarding research subject to oversight by another federal agency. The draft policy states that research under the regulation or purview of another federal agency may proceed under that agency's oversight once applicable approvals have been obtained. NIH should explain how institutions should document such reliance and whether continuing IBC review of amendments, renewals, or other changes is expected for research subject to another agency's oversight, such as FDA-regulated clinical trials.

Finally, implementation resources should provide practical definitions, decision tools, and examples for provisions that may otherwise be interpreted differently across institutions. Priority areas include which vectors qualify for delegated review; the meaning of "well-characterized cell line"; treatment of BSL-1/ABSL-1 transgenic organisms; when primary clinical samples require IBC review; application of the clinical research provisions to cell-based products, probiotics, and similar interventions; and the treatment of previously reviewed, commonly used agents and constructs. These questions emerged repeatedly during WashU's review of the draft policy.

WashU Operational Example: WashU currently uses a five-year IBC approval cycle and maintains 767 active IBC protocols, including 720 pre-clinical and 47 clinical protocols. If existing approvals are permitted to transition through their normal renewal dates, implementation can be phased over time as protocols enter the new three-year de novo review cycle. By contrast, requiring existing protocols to be converted or re-reviewed during the six-month implementation period would concentrate substantial review activity at the same time WashU is revising procedures and information systems, training investigators and reviewers, implementing new review categories, and establishing the Biosafety Assurance process. Clear grandfathering and transition rules would allow institutions to distribute this work according to existing approval dates rather than creating a concentrated administrative burden that does not itself improve biosafety.

Recommendation: NIH should:
• publish final implementation resources sufficiently in advance of the effective date to permit institutions to develop and test the systems, procedures, training, and workflows necessary for compliance;
• establish clear transition and grandfathering rules for existing protocols and approvals, previously reviewed agents and constructs, and previously deselected or otherwise federally characterized strains, including guidance for how current approval periods should transition to the proposed three-year de novo review cycle;
• allow existing protocols to transition through normal renewal cycles when feasible rather than requiring wholesale re-review during the implementation period, and consider lengthening the six-month implementation period if substantial re-review or conversion will be required;
• clarify that de novo renewal review may use delegated review pathways when appropriate based on the risk and characteristics of the continuing research;
• provide detailed instructions for the Biosafety Assurance process, including required documentation, NIH review criteria, renewal procedures, institutional roles, and any pre-award requirements;
• clarify what constitutes adequate periodic review of approved research and when existing institutional inspection or monitoring programs may satisfy that responsibility;
• explain how institutions should implement and document reliance on oversight provided by another federal agency;
• issue definitions, decision tools, FAQs, and practical examples addressing common research activities and ambiguous review categories so that the policy is interpreted consistently across institutions;
• maintain a current, searchable federal resource containing RG classifications and containment determinations that can be relied upon across institutions;
• assess the cumulative implementation burden of the proposed framework and provide practical, scalable resources that support institutions with differing levels of biosafety infrastructure and administrative capacity; and
• ensure that federal review processes and capacity do not create unnecessary research bottlenecks or delays, particularly when institutional action depends on NIH classification or containment guidance.

I am responding: On behalf of an organization

Name: Irwin Gelman, PhD

Name of Organization: Roswell Park Comprehensive Cancer Center

Type of Organization: Healthcare Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer/Oncology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): We agree that risks involving accidents that subject workers to known or potentially infectious agents should be included on our public-facing institutional website. These would be consistent with what were previously referred to as “significant problems, violations or significant research-related accidents and illnesses”. In contrast, we believe that lower risk incidences and accidents should be reported to the Institution only. These include cases where no infectious agents are involved, such as non-skin-breaking mouse scratches or bites, or cuts from glass. Such issues are dealt with internally by our institution’s Occupational Health and Safety Office and not by Biosafety. As these incidents are not significant and do not require NIH notification they should not require public notification.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We propose that meeting minutes should continue to use any format routinely used by the Institute if it includes all the necessary information NIH deems necessary to relay the review process that was performed.
If the draft of the proposed meeting minutes template is ultimately chosen, here are some comments:
i) It would be burdensome to list each IBC member’s title in the minutes, especially because those are already posted on the online committee roster.
ii) Similarly, it would be redundant and cumbersome to document the training certification for each application’s personnel in the meeting minutes; these certifications are validated at the submission of each protocol, and personnel lacking complete training are not allowed to be listed when the application is reviewed at the monthly IBC meeting.

250. New York University & Langone Medical Center

I am responding: On behalf of an organization

Name: IBC Director

Name of Organization: New York University & Langone Medical Center

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: In general, this policy seems to have been conceived without expert input, covers all biological entities in a blanket and overreaching categorization and fails to establish the logic behind the policies.
I believe that this policy revision is unworkable for several overlapping reasons, mostly arising from the apparent classification of all biological entities as one category

The policy as written would seem to require establishing a new and large oversight mechanism to implement or else simply ban useful and innocuous research along with potentially risky research owing to its sweeping generalizations.

1. I do not believe that changing from a list-based approach to a risk-based approach is workable. Who is to assess risk? This will require review of an endless number of experimental proposals and defense on a case by case basis. The other possibility is that the new rules will simply ban all useful research on all biological entities, since there is apparently to be no differentiation between harmless and lethal pathogens.

2. What is “the biological agent”? Similar to point 1., is the proposal to ban all alterations of all biological agents that could alter all replication characteristics that increase their survival?

3. Forbidding "Altering the host range or tropism of the biological agent” is not workable because this is a necessary and standard practice for many biological agents. Without a list-based system that classifies agents according to potential for harm, this bans standard ongoing research.

4. "Generating or reconstituting an eradicated or extinct biological agent.” Is the policy to forbid any thawing of tundra to seek ancient biological entities? This seems unwise. How as this risk been estimated in order to forbid it?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 1. Please provide further clarification on Risk Groups and IBC functions.

3. Continued utility of Risk Groups: 1.Section III-A points to 2 CFR 200.334 for a three year retention period, but then requires minutes and incident reports to stay posted for five years. If an award closes out and the three year clock runs out first, which requirement wins? Institutions need to know whether they are keeping these records solely to satisfy the posting requirement.
2.The policy says a member with a conflict still counts toward quorum. The minutes template says all formal business needs a quorum and that NIH recommends a non-affiliated member be present. Is non-affiliated presence required or just recommended? And if the only non-affiliated members at the meeting have recused themselves, does the committee still have a valid quorum?
3. The incident template requires the PI's name, bars other identifying information, and says the PI's name cannot be redacted. In a two person lab, or when the PI is the person who was exposed, the combination of name, agent, date, position title, and biosafety level identifies the injured employee on a public webpage. How does this work with ADA and HIPAA protections for employee medical information, and with state workers' compensation privacy requirements? We ask that NIH allow the names be withheld.
4. When does the 24 hour clock start? Is it when the exposure is confirmed, or when biosafety first hears about it? We also need to know who at NIH receives the notification and how it gets there. The template says reports must be sent to NIH but gives no address, portal, or file format. Please also clarify whether the clock runs through weekends and federal holidays.
5.The phrase "confirmed or potential laboratory acquired infection" is not defined. Taken literally, almost any needlestick at BSL-2 would meet it. We recommend NIH define this based on the agent and the actual likelihood of infection rather than on whether an exposure happened.
Public posting is tied to NIH's final response. If NIH does not respond, when can the institution post, and when must it? Please set a default timeline so reports do not sit unposted indefinitely while we wait.
6. The scope covers any genetically modified cell, virus, or organism other than plants. Read with Section IV-3, a plasmid in K-12 E. coli would still need delegated review. 7. The exemptions in Section III-F and Appendix C of the current Guidelines appear to be gone. NIH has said one goal is reducing burden for low risk work, and right now there is no exempt tier at all.
8. The definition of laboratory research leaves out deliberate release outside of containment. Field testing is covered under the current Guidelines. Given how much new structure this draft builds around gene drive modified organisms, leaving field release out entirely seems like a gap. Was it intended?
9. The toxin definition is limited to proteins and peptides made by living organisms. That leaves out saxitoxin, tetrodotoxin, T-2 mycotoxin, and other Select Agent toxins that are not proteins. Was this intentional? We suggest matching the Federal Select Agent Program toxin list instead.
10. The prion definition covers disease in humans or animals, but the overall scope is limited to risk to human health. Which one applies to prion and self-aggregating protein work that only affects animals?
11. Biomedical research is defined by NIH mission, yet the policy reaches all research at any institution that receives NIH funding. Would an industry funded agricultural or environmental microbiology project at a university with a single NIH grant be covered? We need this spelled out for affiliated hospitals, separately incorporated research institutes, subrecipients, and shared core facilities.
12. How is the Biosafety Assurance submitted, and how long should we expect review to take? If the effective date arrives and NIH has not yet approved our Assurance, can research continue?
13. The draft allows delegated review of minor amendments but never says what counts as minor. Will NIH publish criteria, or is each IBC expected to define this in its own procedures?

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): As it stands this policy would not apply to Non NIH funded institution's. NIH should build relationships with their neighboring funding oversight bodies if they would like this policy to apply to that group of non NIH funded research . Together you all can build a policy that the other funding bodies can agree to and adapt for research intuitions in which which they provide funding.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1. The draft allows delegated review of minor amendments but never says what counts as minor. Will NIH publish criteria, or is each IBC expected to define this in its own procedures?
2. The sample project overview in the minutes template includes the vector backbone, deletions, transgenes, promoters, routes of administration, and animal models. Posting that level of detail before publication can cost foreign patent rights or breach confidentiality agreements with sponsors. What standard should we apply when redacting unpublished technical detail, and who settles a disagreement about a redaction? The IBC, the institution, or NIH?
3. A BSO is only required for BSL-3, BSL-4, and gene drive work, but the BSO duties have to be assigned to someone regardless. Why not simply require the position and scale the scope to the work being done? Separately, the BSO is a required voting member while also running inspections, investigating incidents, and preparing the risk assessments the committee votes on. Does NIH see an independence problem here? We would ask NIH to consider making the BSO a non-voting member.
4. Each posted item may look harmless on its own. Put the roster, the minutes, the incident reports, and the Assurance disclosures together and you have a map of what agents we hold, who works with them, where, at what containment level, and what has already failed. Please review the posting requirements as a whole for security risk.
5. NIH alone decides containment for novel, emerging, and zoonotic agents, and approves every request to lower containment. There are no published criteria, no deadline, and no appeal. Research stops while we wait. Please explain how these calls will be made and commit to a turnaround time.
6. The draft says research overseen by another federal agency may proceed once that agency approves. Read literally, that could cut the IBC out of anything with a USDA permit, etc. Please confirm IBC review still applies.
7. Please provide further clarification on Risk Groups and IBC functions.
8. Please consider expanding the implementation timeline from Six months to at least one year. New Assurances, new registration reviews, new webpages, new members, and new reporting workflows all hit at once.

6. Other feedback relevant to this resource: 1. Please consider expanding the implementation timeline from Six months to at least one year. New Assurances, new registration reviews, new webpages, new members, and new reporting workflows all hit at once.
2. The exemptions in Section III-F and Appendix C of the current Guidelines appear to be gone. NIH has said one goal is reducing burden for low risk work, and right now there is no exempt tier at all.

Uploaded File: NIH-Policy-Comments-1-1.pdf

NIH Biosafety Policy Comments

- Section III-A points to 2 CFR 200.334 for a three year retention period, but then requires minutes and incident reports to stay posted for five years. If an award closes out and the three year clock runs out first, which requirement wins? Institutions need to know whether they are keeping these records solely to satisfy the posting requirement.

- The policy says a member with a conflict still counts toward quorum. The minutes template says all formal business needs a quorum and that NIH recommends a non-affiliated member be present. Is non-affiliated presence required or just recommended? And if the only non-affiliated members at the meeting have recused themselves, does the committee still have a valid quorum?

- The incident template requires the PI's name, bars other identifying information, and says the PI's name cannot be redacted. In a two person lab, or when the PI is the person who was exposed, the combination of name, agent, date, position title, and biosafety level identifies the injured employee on a public webpage. How does this work with ADA and HIPAA protections for employee medical information, and with state workers' compensation privacy requirements? We ask that NIH allow the names be withheld.

- When does the 24 hour clock start? Is it when the exposure is confirmed, or when biosafety first hears about it? We also need to know who at NIH receives the notification and how it gets there. The template says reports must be sent to NIH but gives no address, portal, or file format. Please also clarify whether the clock runs through weekends and federal holidays.

- The phrase "confirmed or potential laboratory acquired infection" is not defined. Taken literally, almost any needlestick at BSL-2 would meet it. We recommend NIH define this based on the agent and the actual likelihood of infection rather than on whether an exposure happened.

- Public posting is tied to NIH's final response. If NIH does not respond, when can the institution post, and when must it? Please set a default timeline so reports do not sit unposted indefinitely while we wait.

- The scope covers any genetically modified cell, virus, or organism other than plants. Read with Section IV-3, a plasmid in K-12 E. coli would still need delegated review. The exemptions in Section III-F and Appendix C of the current Guidelines appear to be gone. NIH has said one goal is reducing burden for low risk work, and right now there is no exempt tier at all.

- The definition of laboratory research leaves out deliberate release outside of containment. Field testing is covered under the current Guidelines. Given how much new structure this draft builds around gene drive modified organisms, leaving field release out entirely seems like a gap. Was it intended?

- The toxin definition is limited to proteins and peptides made by living organisms. That leaves out saxitoxin, tetrodotoxin, T-2 mycotoxin, and other Select Agent toxins that are not proteins. Was this intentional? We suggest matching the Federal Select Agent Program toxin list instead.

- The prion definition covers disease in humans or animals, but the overall scope is limited to risk to human health. Which one applies to prion and self-aggregating protein work that only affects animals?

- Biomedical research is defined by NIH mission, yet the policy reaches all research at any institution that receives NIH funding. Would an industry funded agricultural or environmental microbiology project at a university with a single NIH grant be covered? We need this spelled out for affiliated hospitals, separately incorporated research institutes, subrecipients, and shared core facilities.

- How is the Biosafety Assurance submitted, and how long should we expect review to take? If the effective date arrives and NIH has not yet approved our Assurance, can research continue?

- The draft allows delegated review of minor amendments but never says what counts as minor. Will NIH publish criteria, or is each IBC expected to define this in its own procedures?

- The sample project overview in the minutes template includes the vector backbone, deletions, transgenes, promoters, routes of administration, and animal models. Posting that level of detail before publication can cost foreign patent rights or breach confidentiality agreements with sponsors. What standard should we apply when redacting unpublished technical detail, and who settles a disagreement about a redaction? The IBC, the institution, or NIH?

- A BSO is only required for BSL-3, BSL-4, and gene drive work, but the BSO duties have to be assigned to someone regardless. Why not simply require the position and scale the scope to the work being done? Separately, the BSO is a required voting member while also running inspections, investigating incidents, and preparing the risk assessments the committee votes on. Does NIH see an independence problem here? We would ask NIH to consider making the BSO a non-voting member.

- Each posted item may look harmless on its own. Put the roster, the minutes, the incident reports, and the Assurance disclosures together and you have a map of what agents we hold, who works with them, where, at what containment level, and what has already failed. Please review the posting requirements as a whole for security risk.

- NIH alone decides containment for novel, emerging, and zoonotic agents, and approves every request to lower containment. There are no published criteria, no deadline, and no appeal. Research stops while we wait. Please explain how these calls will be made and commit to a turnaround time.

- The draft says research overseen by another federal agency may proceed once that agency approves. Read literally, that could cut the IBC out of anything with a USDA permit, etc. Please confirm IBC review still applies.

- Please provide further clarification on Risk Groups and IBC functions.

- Please consider expanding the implementation timeline from Six months to at least one year. New Assurances, new registration reviews, new webpages, new members, and new reporting workflows all hit at once.

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious diseases, toxins

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. In the definition of biological agents, the terminology for 'parasites' is not precise. Some organisms may have virulence or pathogenicity that depends on the host state or on the presence of other organisms/microorganisms.
2. In the definition of biological agents: It is unclear whether organisms that do not cause a human disease but aggravate it are included.
3. Definition of ‘Genetic Modification’: The modes of introduction of mutations into cells, organisms, or viruses are defined as ‘passaging, reassortment, chemical or radiological means’. Are other strategies for mutagenesis not covered (for example, ultrasound)?
4. Definition of ‘Novel agent or organism’: The definition as ‘an agent or organism not existing in nature’ is not well-defined. A particular mutation in a bacterial cell that confers antibiotic resistance, for example, is likely to exist in nature.
5. Defining ‘Wild type’ as ‘Naturally occurring organisms, cells, or viruses without deliberately introduced genetic modifications’ is ambiguous. For example, lab domestication of bacterial and fungal species is naturally occurring; is that included in this category? Alternatively, a mutation evolved/engineered in the lab may also be discovered naturally, for example, in antibiotic resistance. Would the lab-engineered strain still be considered wild type?
6. Definition of Toxin: Toxins are defined as ‘a protein or peptide,’ which is incomplete. There are important categories of toxins that cause harm in humans but are not proteins or peptides (e.g., mycotoxins or higher concentrations of some antibiotics).
7. Formatting issue: The abbreviation GDMO is not defined at the beginning of the document (it appears later).

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): 1. “Supervising the performance of laboratory staff to

ensure that the required safety practices and techniques are employed and correcting any errors.” This is not currently part of IBC oversight responsibilities. The mechanisms and extent of this expectation need to be clarified.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: 1. "Adhering to all IBC-approved plans, including emergency response for handling accidental spills, personnel contamination, post-exposure response, loss of containment or release of biohazards, waste disposal, or other incidents involving research covered under the Policy." It is unclear how the IBC-approved emergency response plan (related to biohazards) will be distinguished from the general lab safety emergency response. It is unclear which responsibilities fall under the "IBC-approved" designation, because there is overlap in expectations.
2. Regarding "Submitting the initial research protocol and any subsequent changes that may alter the biorisk assessment of the research to be conducted, to the IBC and NIH (as appropriate), for review and approval." For this requirement, it would be important to clarify what level of alteration of the biorisk should be reported and what the expected timeline is for the IBC or NIH's review and approval.

Description: Comments from the Boston College community

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As a biosafety compliance professional responsible for assisting investigators, institutional review bodies, and institutional officials with implementing biosafety requirements, I am concerned that several key definitions within the draft policy lack the specificity needed to support consistent implementation across institutions. Throughout the document, broad concepts are introduced without sufficient objective criteria, examples, or decision frameworks. As a result, institutions acting in good faith may reach substantially different conclusions regarding whether research falls within scope and what oversight obligations apply.

I am particularly concerned that the policy claims to be a policy about human biosafety concerns but retains many environmental considerations. The policy essentially takes the NIH guidelines for r/sNA and picks and chooses key concepts from that policy to keep and others to discard without a justification provided.

Biological Agent Definition

The proposed definition of Biological Agent appears substantially broader than existing frameworks and may encompass a wide range of research activities that have historically not been subject to significant biosafety oversight.

From an implementation perspective, institutions will need to determine whether ongoing and proposed research activities fall within the scope of the policy. However, the definition does not clearly establish whether the policy is intended primarily to address risks to human health or whether it is intended to encompass broader concerns such as ecological impacts, environmental risks, agricultural considerations, animal health concerns, self-aggregating proteins, prions, toxins, and other biological materials.

Institutions will need concrete examples demonstrating what NIH intends to include and exclude. Without such examples, different institutions may apply substantially different interpretations to similar activities.

Emerging Organism Definition

The definition of Emerging Organism presents significant implementation challenges because it provides no clear mechanism for determining when an organism becomes "emerging."

As written, the policy does not indicate:
• Whether emergence should be evaluated at a local, regional, national, or global level.
• What information sources institutions should rely upon.
• Who is responsible for making the determination.
• Whether determinations should be periodically reassessed.

As someone who routinely assists investigators in determining applicable oversight requirements, I would find it difficult to provide consistent guidance under the current definition.

NIH should provide objective criteria, examples, and authoritative reference sources to support institutional decision making.

Novel Organism Definition

Similar concerns exist regarding the definition of Novel Organism.

The term "novel" may reasonably be interpreted in numerous ways, including:
• Novel taxonomy.
• Novel genetic composition.
• Novel phenotype.
• Novel pathogenicity.
• Novel environmental characteristics.
• Novel host range.

The policy does not clearly identify what form of novelty is intended to trigger additional oversight requirements.
Without greater specificity, institutions may apply significantly different standards to similar research activities.

Zoonotic Agents
The policy introduces concepts such as organisms that are "reasonably suspected" to infect humans. While this language may provide flexibility, it also introduces substantial subjectivity.
Institutions would benefit from guidance regarding:
• Acceptable evidence standards.
• Authoritative data sources.

• Documentation expectations.
• Reassessment requirements as scientific knowledge evolves.
Without these elements, institutions may develop inconsistent approaches to evaluating zoonotic agents.

Scope of Oversight for Genetically Modified Organisms and Cells
One of my primary implementation concerns involves the potential scope of oversight for genetically modified organisms and cells.
The draft does not clearly address how common research materials previously exempted or where the draft policy creates ambiguity as to whether they are included or excluded including:
• Recombinant yeast systems.
• Recombinant bacterial systems.
• Commercially available modified cell lines.
• Gene-edited cell lines.
• Immortalized cell lines.
• Transgenic animals.
• Genome-edited animal models.

Because these systems are widely used throughout the research enterprise, even small differences in interpretation could have significant consequences for institutional workload, review timelines, and investigator burden.
NIH should provide detailed examples illustrating intended oversight pathways for common research models.

Exclusion of Plants
The apparent exclusion of genetically modified plants is difficult to reconcile with the broader themes of the policy.
The draft repeatedly emphasizes phenotype-based risk assessment, potential environmental impacts, and emerging biotechnologies. However, genetically modified plants appear to receive substantially different treatment.
Additional explanation regarding the scientific and regulatory rationale for this distinction would improve consistency and transparency.
Recommendation
NIH should provide clearer definitions, detailed examples, decision aids, and implementation guidance that allows institutions to consistently determine what research falls within scope.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support the policy's emphasis on risk assessment and the concept of matching oversight to risk. However, the current draft frequently directs institutions to perform risk assessments without providing sufficient guidance regarding how those assessments should be conducted.
As written, the policy may inadvertently create wide variation in oversight practices among institutions.
Risk Assessment Methodology
The policy treats risk assessment as the foundation for numerous oversight decisions, including:
• Containment determinations.
• Oversight pathways.

• Reporting obligations.
• Institutional review requirements.

However, the policy provides little practical guidance on how institutions should conduct these assessments.

The draft does not adequately address:

• Weighting of risk factors.
• Management of uncertainty.
• Documentation expectations.
• Reviewer qualifications.
• Required elements of risk assessments.

If risk assessment is intended to become the central decision-making mechanism under the policy, NIH should provide standardized methodologies, decision trees, and worked examples.

Delegated Review

The delegated review provisions create significant operational uncertainty.

The draft does not clearly explain:

• Which activities qualify.
• Who performs the review.
• Required documentation.
• Reporting obligations to the IBC.
• Record retention expectations.

Because many historically exempt activities may now move into delegated review pathways, even small ambiguities could result in significant documentation burden.

As someone involved in protocol review workflows and committee support activities, I anticipate institutions struggling to implement these provisions consistently without additional guidance.

Well-Characterized Systems

Multiple sections of the policy rely upon concepts such as "well-characterized organisms" and "well-characterized cell lines."

The policy does not establish objective criteria for determining when a biological system is sufficiently characterized.

Questions likely to arise include:

• Does widespread use constitute characterization?
• Is published literature sufficient?
• Are commercial products automatically considered characterized?
• How should modified derivatives be evaluated?

These classifications may directly affect oversight requirements and therefore require greater clarity.

Roles and Responsibilities

Throughout the policy, responsibilities are frequently assigned to:

• Institutions.
• Institutional Officials.
• Biosafety Officers.
• Institutional Biosafety Committees.
• Principal Investigators.
• NIH.

However, the distinctions among these responsibilities are not always clear.

An implementation matrix identifying primary, supporting, and oversight responsibilities would promote consistency and reduce institutional confusion.
Recommendation
NIH should provide implementation resources that explain not only what decisions must be made but how those decisions are expected to be made in practice.

3. Continued utility of Risk Groups: The draft appears to retain Risk Groups while simultaneously emphasizing broader risk assessment principles. However, the relationship among Risk Groups, Biosafety Levels, and institutional risk assessment is not fully explained.
As someone responsible for assisting investigators and reviewers in applying these concepts, I am concerned that institutions may struggle to determine how these frameworks interact.
Utility of Risk Groups
The policy introduces numerous considerations that extend beyond traditional Risk Group frameworks, including:
• Host range.
• Environmental persistence.
• Ecological effects.
• Gene-drive characteristics.
• Novel phenotypes.
• Synthetic biology considerations.
While these factors may be important, it is unclear whether Risk Groups remain the primary classification tool or have become only one component of a broader assessment process.
Expanded Definition of Genetic Modification
The inclusion of passaging, reassortment, chemical mutagenesis, and radiological mutagenesis raises important implementation questions.
The policy does not clearly explain:
• Why these methods warrant oversight.
• Whether oversight is based on methodology or phenotype.
• How naturally occurring changes should be treated.
• How institutions should document these determinations.
These questions will directly affect oversight decisions and should be addressed more explicitly.
Recommendation
NIH should provide detailed case studies demonstrating how Risk Groups, containment levels, and institutional risk assessment are expected to interact under the new framework.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The success of voluntary adoption will depend heavily on whether institutions can understand and implement the framework in a practical and resource-conscious manner.
Many significant implementation details remain undefined.
Supporting Resources
Throughout the policy, NIH references future:
• Guidance documents.
• Templates.
• Best practices.

• Reporting tools.
• Educational materials.

However, institutions are currently being asked to evaluate the framework without reviewing these resources.

As an individual who would likely participate in developing institutional implementation strategies, I find it difficult to estimate the true impact of the policy without these supporting materials.

National Biosafety Data and Safety Analysis Center

The proposed NBDSAC may serve an important role, but its operational model remains unclear.

Institutions would benefit from additional information regarding:

• Governance.
• Data management.
• Reporting expectations.
• Data utilization.
• Confidentiality protections.

Recommendation

NIH should consider releasing implementation resources alongside future policy drafts to support more informed public feedback.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The transparency and reporting provisions represent one of the most significant operational changes within the draft policy. While transparency is important, several provisions may create substantial burden without a clearly articulated biosafety benefit.

Reportable Incidents

The policy would benefit from clearer distinctions between:

• Biosafety incidents.
• Near misses.
• Occupational injuries.
• Facility events.
• Equipment failures.
• Administrative errors.

Institutions require objective reporting thresholds to promote consistency.

Without clear thresholds, similar events may be reported differently across institutions.

Twenty-Four-Hour Reporting Requirements

The proposed twenty-four-hour reporting requirement raises practical implementation concerns.

Immediately following an incident, institutional efforts are focused on:

• Protecting personnel.
• Stabilizing operations.
• Conducting preliminary assessments.
• Determining root causes.

At that stage, critical facts are often still developing.

NIH should clarify what information is realistically expected within the first twenty-four hours and how preliminary reporting differs from final investigative reporting.

Additionally, NIH should consider the practical value and intended purpose of the initial notification requirement. If the primary purpose of the notification is simply to establish awareness of an event and a timeline for submission of a subsequent investigative report, it is unclear what advantage a 24-hour
