reporting requirement provides compared to a longer reporting timeframe, such as 72 hours.
During the initial stages of incident response, institutional efforts are appropriately focused on personnel safety, medical evaluation where necessary, containment, fact gathering, and assessment of reportability. These activities often occur while information is still developing and before the institution has sufficient details to provide meaningful context regarding the event.
Based on my professional experience submitting incident reports to NIH, initial notifications are rarely accompanied by immediate feedback, consultation, or response from NIH that would alter the institution's immediate response activities. If NIH does not anticipate playing an active role during the initial response phase, the policy should clearly articulate the benefit of a 24-hour reporting requirement and how that benefit outweighs the administrative burden imposed on institutions during a critical response period. Absent such justification, a modestly longer reporting window may allow institutions to provide more accurate and useful information while maintaining timely federal awareness of significant incidents.
A slightly longer reporting window may also improve the quality and reliability of the information submitted. Institutions would be better positioned to provide a more accurate description of the event, preliminary causal factors, immediate corrective actions, and an informed assessment of actual risk rather than submitting notifications based on incomplete information that may subsequently require correction.
Public Disclosure Requirements
Public posting requirements warrant careful consideration.
While transparency can promote accountability, disclosure provisions should also consider:
• Personnel privacy.
• Institutional confidentiality.
• Biosecurity considerations.
• Potential disincentives to self-reporting.
In some research communities, even heavily redacted reports may allow affected laboratories or individuals to be identified.
This risk should be carefully evaluated.
Meeting Minutes
The policy should clearly define:
• What constitutes approved minutes.
• Publication timelines.
• Redaction standards.
• Treatment of sensitive information.
Institutions will struggle to implement consistent practices without this guidance.
Recommendation
NIH should adopt a more risk-based approach to reporting and provide model templates reflecting privacy, biosafety, and biosecurity considerations. NIH should avoid prescribing a specific institutional governance process for the approval and publication of IBC meeting minutes. Institutions already operate under established procedures for record review, approval, and public posting. The policy's objective should be timely public availability of approved minutes rather than dictating how institutions reach approval. Allowing institutions to define approved minutes through their own documented procedures and requiring publication within a reasonable timeframe, such as 72 hours after final approval, would better accommodate institutional variations while still supporting transparency.

6. Other feedback relevant to this resource: My single greatest concern with the draft policy is that many of its most consequential provisions rely upon implementation resources that have not yet been released.

As someone who would likely be involved in translating this policy into institutional procedures, workflows, committee practices, investigator guidance, and training materials, I find it difficult to assess the practicality of many requirements in the absence of those resources.

Operational Planning Challenges

Institutions cannot accurately estimate:

• Staffing requirements.
• Training needs.
• Information technology modifications.
• Committee workload.
• Administrative burden.
• Compliance costs.

Without these estimates, it is difficult to assess the full impact of the policy.

NIH Review Processes

Several provisions rely upon future NIH review and consultation mechanisms involving novel, emerging, and other specialized biological agents.

However, the draft provides limited information regarding:

• Responsible offices.
• Review timelines.
• Submission processes.
• Escalation procedures.
• Appeals mechanisms.

Because institutional decisions may depend upon these processes, additional detail is necessary.

Institutional Resources

Successful implementation will require significant investments in:

• Policy development.
• Training programs.
• Investigator education.
• Electronic management systems.
• Committee administration.
• Risk assessment programs.

Many institutions will need substantial lead time to complete this work.

Implementation Timeline

The proposed six-month implementation timeline appears unlikely to provide sufficient time for institutions to:

• Revise policies.
• Develop procedures.
• Build training programs.
• Modify software systems.
• Train stakeholders.
• Establish governance structures.

A phased implementation approach would appear more realistic and likely more successful.

Recommendation

NIH should provide implementation guidance before finalizing requirements, expand stakeholder engagement around operational impacts, and consider a phased implementation strategy that allows institutions sufficient time to develop sustainable compliance programs.

From an implementation and governance perspective, I am concerned that the draft policy relies heavily on future guidance documents to define many of the substantive standards institutions will ultimately be expected to meet. While guidance can be an effective tool for providing examples, best practices, and implementation support, it should not serve as the primary mechanism for establishing core compliance requirements.

As currently written, many key standards, processes, and expectations remain undefined and are deferred to future guidance documents that have not yet been released. This creates challenges for stakeholders attempting to evaluate the practical impact of the policy and limits the ability of institutions to provide meaningful feedback during the public comment process.

More broadly, substantive compliance obligations should be established within the policy itself, where they are subject to public review, comment, and transparency. Guidance documents should then be used to explain, interpret, and operationalize those requirements rather than create them.

I recommend that NIH incorporate the core standards, decision criteria, and institutional expectations directly within the policy and reserve guidance documents for implementation examples, recommended practices, case studies, and other supporting resources. Doing so would improve transparency, provide greater regulatory certainty, and allow stakeholders to more fully evaluate the impact of the proposed framework before it is finalized.

253. Cornell University

I am responding: On behalf of an organization

Name:

Name of Organization: Cornell University

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft policy substantially expands biosafety oversight beyond the framework historically established under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules. While we recognize the rationale for updating oversight frameworks to reflect emerging technologies and new categories of biological research, the boundaries of covered research are not always clearly defined. For example, the draft appears to bring genetically modified cells, organisms, and viruses broadly into scope while introducing previously unaddressed genetic modification techniques, including passaging, reassortment, chemical mutagenesis and radiological mutagenesis, creating uncertainty regarding the intended scope of institutional oversight and review requirements.

Throughout the policy, there appears to be tension between provisions focused on risks to human health and provisions that address broader ecological, environmental, agricultural, and biotechnology considerations. As a result, it is not always clear whether the policy is intended primarily as a human-health biosafety framework or a broader biotechnology oversight framework. The policy should clearly define whether it is intended to address only direct human health risks or broader biological risks affecting animal health, agriculture, food systems, and the environment, and ensure that any inclusion or exclusion of these hazards is scientifically justified and applied consistently. Additionally, the policy would benefit from clearly stating whether activities previously exempted under the NIH Guidelines for research involving recombinant or synthetic nucleic acid molecules are now subject to institutional review requirements.

Additional clarification regarding the intended scope of covered research would improve implementation consistency and assist institutions in determining when activities are subject to policy requirements.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The draft policy places institutional risk assessment at the center of numerous oversight decisions, including containment determinations, review pathways, incident reporting obligations, and evaluation of genetically modified, emerging, zoonotic, and novel biological systems. While institutional flexibility is important, the policy provides limited guidance regarding how risk assessments should be conducted, how competing factors

should be evaluated, and how uncertainty should be managed. As written, institutions with similar expertise may reasonably arrive at different conclusions when evaluating comparable research activities.

The draft policy also does not clearly describe the status of institutional risk assessments once they have been completed. Institutions may encounter complex research activities for which a risk assessment indicates the work is consistent with the policy, but for which limited NIH precedent or guidance exists. In these situations, institutions will rely upon the expertise of their Institutional Biosafety Committee (IBC)s, Biosafety Officer (BSO)s, and subject matter experts to conduct risk assessments and implement appropriate containment measures. The policy would benefit from clarifying the extent to which institutions may rely upon well-documented, good-faith risk assessments conducted in accordance with the policy until NIH provides alternative guidance or determinations. If consistency across the research enterprise is an intended objective, NIH should consider providing additional methodologies, examples, implementation guidance, and decision frameworks to support institutional decision-making.

3. Continued utility of Risk Groups: The draft policy frequently relies upon subjective phrases such as "appropriate," "reasonable," "well-characterized," "periodic," "immediate," and "maximum extent possible." Although such concepts are commonly used in performance-based regulatory frameworks, the policy often does not identify the responsible decision-maker or provide criteria supporting consistent interpretation.

Additional clarification regarding decision criteria, responsible parties, and institutional decision-making authority would improve implementation consistency. Where subjective standards are necessary, the policy should clearly identify the institutional office, official, or committee responsible for making the determination and provide sufficient criteria to support consistent application. The policy should allow institutions to make and document these determinations through their established biosafety oversight programs rather than relying on repeated NIH interpretation of individual situations.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The draft policy introduces substantial new administrative requirements, including Biosafety Assurances, public-facing website requirements, incident reporting obligations, expanded documentation requirements, public posting of records, and delegated-review reporting obligations.

While we understand the goals associated with these requirements, the policy would benefit from a clearer explanation of how these activities are expected to improve biosafety outcomes, strengthen biosafety culture, reduce incidents, or otherwise advance the objectives of the policy. Institutions will ultimately need to dedicate finite resources toward policy implementation. Additional discussion regarding the intended benefits of major administrative requirements would assist institutions in understanding the rationale for these changes and evaluating implementation priorities.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Transparency is a central feature of the draft policy and represents a significant shift in biosafety oversight. While transparency is an important objective, the policy would benefit from a clearer explanation regarding how public disclosure is expected to improve biosafety outcomes, strengthen safety culture, reduce incidents, or improve accountability.

The transparency provisions may also unintentionally discourage reporting by increasing concerns regarding confidentiality, public scrutiny, and potential re-identification of individuals involved in incidents. Without clear definitions of reportable incidents and reporting timelines, institutions may be compelled to report routine operational events, particularly in BSL-3 and BSL-4 environments, that do not compromise containment or present a credible biosafety consequence, increasing administrative burden and potentially undermining a strong reporting culture. A strong biosafety culture depends upon prompt and candid reporting of mistakes, near-misses, and incidents. Institutions may be less likely to achieve that outcome if investigators and staff perceive that incident information will become publicly accessible.

Additionally, the policy should more carefully consider the biosecurity implications of its transparency requirements. While individual disclosures may appear low risk in isolation, the cumulative publication of meeting minutes, incident reports, research descriptions, investigator information, biological agents, and facility details may create an aggregate risk by allowing external parties to assemble a more complete picture of an institution's biological research activities, capabilities, and holdings.
We encourage NIH to further evaluate how transparency objectives can be balanced with biosafety, biosecurity, privacy, and reporting-culture considerations.

6. Other feedback relevant to this resource: Many critical operational details appear to be deferred to future implementation resources, guidance documents, templates, and supporting materials that are not currently available for review. As a result, institutions are being asked to evaluate and comment on a framework whose practical implementation remains partially undefined.
Without access to these materials, institutions cannot accurately assess implementation costs, staffing requirements, information technology needs, training expectations, compliance timelines, or administrative burden.

We encourage NIH to release draft implementation resources, guidance materials, templates, and decision frameworks for public review. Because these materials will likely have a substantial impact on how institutions comply with the policy, we believe stakeholders would benefit from an additional opportunity to review and comment on these resources before the policy is finalized.

The draft policy substantially expands responsibilities for institutions, IBCs, BSOs, PIs, and NIH. However, the policy frequently assigns responsibilities without clearly identifying authority, accountability, or implementation pathways. Similarly, the policy assigns significant new responsibilities to NIH without clearly identifying which offices will be responsible for implementation, policy interpretation, review activities, and institutional support. Successful implementation will require both institutions and NIH to understand who is responsible for specific activities and how those responsibilities will be operationalized in practice. Additional clarity regarding governance structures, roles, responsibilities, and decision-making authority would significantly improve implementation and compliance.

The proposed six-month implementation period appears insufficient given the scale of changes contemplated by the policy. Institutions will likely need to revise policies, modify review systems, update training programs, establish new reporting workflows, develop public-facing transparency infrastructure, update committee procedures, review existing research portfolios to identify newly covered activities, and develop and implement new procedures for activities newly covered under the policy, all of which

will require sufficient implementation time. Implementation may be particularly challenging if activities that were previously exempt under the NIH Guidelines become subject to institutional review requirements under the new framework. At the same time, NIH will need to develop implementation guidance, establish review processes, review Biosafety Assurances, respond to institutional questions, and operationalize several new oversight functions. Given the breadth of these changes and the continued reliance on future guidance documents, NIH should consider extending the implementation period, adopting a phased implementation strategy, or providing additional transition time following release of final implementation resources. A longer implementation timeline would improve consistency, reduce institutional burden, and allow both NIH and the research community sufficient time to establish sustainable compliance programs.

Cornell University and Weill Cornell Medicine appreciate NIH's efforts to modernize biosafety oversight and supports the shared goal of promoting the safe, responsible, and effective conduct of biological research. With significant implementation details still pending, institutions are unable to fully assess the policy's impact. We recommend that NIH release supporting guidance for public review and establish an extended implementation timeline that reflects the breadth of changes required. We encourage NIH to continue engaging with stakeholders as the policy evolves and to consider additional clarification, implementation guidance, and phased implementation strategies that support consistent adoption across the research community. We look forward to continued collaboration in advancing a biosafety framework that is both effective and practical for institutions to implement.

Re: Draft NIH Biosafety Policy for Research Involving Biohazards

To Whom It May Concern:

Cornell University and Weill Cornell Medicine appreciate the opportunity to provide comments on the Draft NIH Biosafety Policy for Research Involving Biohazards. We support NIH's efforts to modernize biosafety oversight and recognize the importance of maintaining robust institutional biosafety programs capable of addressing advances in biotechnology, synthetic biology, emerging biological systems, and evolving research methodologies.

We commend the effort to develop a framework that advances biosafety oversight while supporting a diverse research enterprise. However, several aspects of the proposal would benefit from additional clarification, implementation guidance, and additional stakeholder engagement prior to finalization. The comments below are intended to support this effort by identifying areas where additional clarity, guidance, and alignment will help institutions apply the policy consistently and effectively.

1. Expansion and Definition of Covered Research

The draft policy substantially expands biosafety oversight beyond the framework historically established under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules. While we recognize the rationale for updating oversight frameworks to reflect emerging technologies and new categories of biological research, the boundaries of covered research are not always clearly defined. For example, the draft appears to bring genetically modified cells, organisms, and viruses broadly into scope while introducing previously unaddressed genetic modification techniques, including passaging, reassortment, chemical mutagenesis and radiological mutagenesis, creating uncertainty regarding the intended scope of institutional oversight and review requirements.

Throughout the policy, there appears to be tension between provisions focused on risks to human health and provisions that address broader ecological, environmental, agricultural, and biotechnology considerations. As a result, it is not always clear whether the policy is intended primarily as a human-health biosafety framework or a broader biotechnology oversight framework. The policy should clearly define whether it is intended to address only direct human health risks or broader biological risks affecting animal health, agriculture, food systems, and the environment, and ensure that any inclusion or exclusion of these hazards is scientifically justified and applied consistently. Additionally, the policy would benefit from clearly stating whether activities previously exempted

under the NIH Guidelines for research involving recombinant or synthetic nucleic acid molecules are now subject to institutional review requirements.

Additional clarification regarding the intended scope of covered research would improve implementation consistency and assist institutions in determining when activities are subject to policy requirements.

2. Reliance on Risk Assessment as the Principal Oversight Mechanism

The draft policy places institutional risk assessment at the center of numerous oversight decisions, including containment determinations, review pathways, incident reporting obligations, and evaluation of genetically modified, emerging, zoonotic, and novel biological systems.

While institutional flexibility is important, the policy provides limited guidance regarding how risk assessments should be conducted, how competing factors should be evaluated, and how uncertainty should be managed. As written, institutions with similar expertise may reasonably arrive at different conclusions when evaluating comparable research activities.

The draft policy also does not clearly describe the status of institutional risk assessments once they have been completed. Institutions may encounter complex research activities for which a risk assessment indicates the work is consistent with the policy, but for which limited NIH precedent or guidance exists. In these situations, institutions will rely upon the expertise of their Institutional Biosafety Committee (IBC)s, Biosafety Officer (BSO)s, and subject matter experts to conduct risk assessments and implement appropriate containment measures. The policy would benefit from clarifying the extent to which institutions may rely upon well-documented, good-faith risk assessments conducted in accordance with the policy until NIH provides alternative guidance or determinations.

If consistency across the research enterprise is an intended objective, NIH should consider providing additional methodologies, examples, implementation guidance, and decision frameworks to support institutional decision-making.

3. Reliance on Subjective Standards

The draft policy frequently relies upon subjective phrases such as "appropriate," "reasonable," "well-characterized," "periodic," "immediate," and "maximum extent possible."

Although such concepts are commonly used in performance-based regulatory frameworks, the policy often does not identify the responsible decision-maker or provide criteria supporting consistent interpretation.

Additional clarification regarding decision criteria, responsible parties, and institutional decision-making authority would improve implementation consistency. Where subjective standards are necessary, the policy should clearly identify the institutional office, official, or committee responsible for making the determination and provide sufficient criteria to support consistent application. The policy should allow institutions to make and document these determinations through their established biosafety oversight programs rather than relying on repeated NIH interpretation of individual situations.

4. Administrative Burden Relative to Biosafety Benefit

The draft policy introduces substantial new administrative requirements, including Biosafety Assurances, public-facing website requirements, incident reporting obligations, expanded documentation requirements, public posting of records, and delegated-review reporting obligations.

While we understand the goals associated with these requirements, the policy would benefit from a clearer explanation of how these activities are expected to improve biosafety outcomes, strengthen biosafety culture, reduce incidents, or otherwise advance the objectives of the policy.

Institutions will ultimately need to dedicate finite resources toward policy implementation. Additional discussion regarding the intended benefits of major administrative requirements would assist institutions in understanding the rationale for these changes and evaluating implementation priorities.

5. Transparency Requirements, Reporting Culture, and Biosecurity Considerations

Transparency is a central feature of the draft policy and represents a significant shift in biosafety oversight.

While transparency is an important objective, the policy would benefit from a clearer explanation regarding how public disclosure is expected to improve biosafety outcomes, strengthen safety culture, reduce incidents, or improve accountability.

The transparency provisions may also unintentionally discourage reporting by increasing concerns regarding confidentiality, public scrutiny, and potential re-identification of individuals involved in incidents. Without clear definitions of reportable incidents and reporting timelines, institutions may be compelled to report routine operational events, particularly in BSL-3 and BSL-4 environments, that do not compromise containment or present a credible biosafety consequence, increasing administrative burden and potentially undermining a strong reporting culture. A strong biosafety culture depends upon prompt and candid reporting of mistakes, near-misses, and incidents. Institutions may be less likely to achieve that outcome if investigators and staff perceive that incident information will become publicly accessible.

Additionally, the policy should more carefully consider the biosecurity implications of its transparency requirements. While individual disclosures may appear low risk in isolation, the cumulative publication of meeting minutes, incident reports, research descriptions, investigator information, biological agents, and facility details may create an aggregate risk by allowing external parties to assemble a more complete picture of an institution's biological research activities, capabilities, and holdings.

We encourage NIH to further evaluate how transparency objectives can be balanced with biosafety, biosecurity, privacy, and reporting-culture considerations.

6. Reliance on Future Guidance Documents

Many critical operational details appear to be deferred to future implementation resources, guidance documents, templates, and supporting materials that are not currently available for review.

As a result, institutions are being asked to evaluate and comment on a framework whose practical implementation remains partially undefined.

Without access to these materials, institutions cannot accurately assess implementation costs, staffing requirements, information technology needs, training expectations, compliance timelines, or administrative burden.

We encourage NIH to release draft implementation resources, guidance materials, templates, and decision frameworks for public review. Because these materials will likely have a substantial impact on how institutions comply with the policy, we believe stakeholders would benefit from an additional opportunity to review and comment on these resources before the policy is finalized.

7. Governance, Authority, and Implementation Structure

The draft policy substantially expands responsibilities for institutions, IBCs, BSOs, PIs, and NIH. However, the policy frequently assigns responsibilities without clearly identifying authority, accountability, or implementation pathways.

Similarly, the policy assigns significant new responsibilities to NIH without clearly identifying which offices will be responsible for implementation, policy interpretation, review activities, and institutional support.

Successful implementation will require both institutions and NIH to understand who is responsible for specific activities and how those responsibilities will be operationalized in practice. Additional clarity regarding governance structures, roles, responsibilities, and decision-making authority would significantly improve implementation and compliance.

8. Implementation Timeline

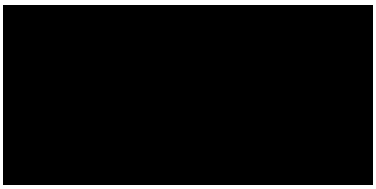
The proposed six-month implementation period appears insufficient given the scale of changes contemplated by the policy.

Institutions will likely need to revise policies, modify review systems, update training programs, establish new reporting workflows, develop public-facing transparency infrastructure, update committee procedures, review existing research portfolios to identify newly covered activities, and develop and implement new procedures for activities newly covered under the policy, all of which will require sufficient implementation time. Implementation may be particularly challenging if activities that were previously exempt under the NIH Guidelines become subject to institutional review requirements under the new framework. At the same time, NIH will need to develop implementation guidance, establish review processes, review Biosafety Assurances, respond to institutional questions, and operationalize several new oversight functions.

Given the breadth of these changes and the continued reliance on future guidance documents, NIH should consider extending the implementation period, adopting a phased implementation strategy, or providing additional transition time following release of final implementation resources.

A longer implementation timeline would improve consistency, reduce institutional burden, and allow both NIH and the research community sufficient time to establish sustainable compliance programs.

Conclusion



Cornell University and Weill Cornell Medicine appreciate NIH's efforts to modernize biosafety oversight and supports the shared goal of promoting the safe, responsible, and effective conduct of biological research. With significant implementation details still pending, institutions are unable to fully assess the policy's impact. We recommend that NIH release supporting guidance for public review and establish an extended implementation timeline that reflects the breadth of changes required. We encourage NIH to continue engaging with stakeholders as the policy evolves and to consider additional clarification, implementation guidance, and phased implementation strategies that support consistent adoption across the research community. We look forward to continued collaboration in advancing a biosafety framework that is both effective and practical for institutions to implement.

Thank you for the opportunity to provide feedback on this important policy initiative.

Respectfully submitted,

Hugh C. Hemmings, Jr, MD, PhD, FRCA

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): biosafety

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Many definitions need added and/or clarified.

Reporting incidents with names and grant numbers could kill reporting culture and cause PIs to not report. If the intention is to provide robust metrics related to incidents, it can be done by scrubbing of personal identifying information and used to track and trend that way.

Public posting could share agent information with bad actors who could try to come on campus and steal.

NIH would need to provide training and financial support to prop up. Indirect spending cuts have already slashed budgets for research compliance.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

Subject: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Support for CSHEMA Recommendations

To Whom It May Concern:

I am submitting this comment in response to the National Institutes of Health (NIH) effort to modernize and strengthen the oversight of biosafety.

I support the comment submitted by the **Campus Safety, Health, and Environmental Management Association (CSHEMA)** regarding this effort. CSHEMA's comment appropriately reflects the needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

As an individual Biosafety Officer, my work would be directly impacted by a new NIH policy on biosafety and I support the recommendations outlined by CSHEMA.

Thank you for the opportunity to comment.

Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards

Response to NOT-OD-26-112

October 12, 2026

Submitted Electronically

The Campus Safety, Health, and Environmental Management Association (CSHEMA) is the premier association for environmental health and safety leadership in higher education. CSHEMA represents institutions that range from large research-intensive universities with mature biosafety programs to smaller colleges that may have limited or no dedicated biosafety staff. Our members include biosafety professionals, environmental health and safety practitioners, and institutional leaders responsible for implementing biosafety requirements across diverse research and teaching environments.

CSHEMA appreciates NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions. **Due to such uncertainty in the final requirements, CSHEMA encourages NIH to provide an opportunity for public review and comment on the next draft before it is finalized.**

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." The policy should clarify whether precautionary post exposure prophylactic treatment is considered "agent-specific treatment". It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

6. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

CSHEMA recommends that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

Conclusion

CSHEMA supports NIH's goal of modernizing biosafety oversight and appreciates the draft's movement toward broader risk awareness, clearer incident thresholds, delegated review, and national safety learning. For the policy to succeed, however, modernization must strengthen the institutional systems that perform biosafety work rather than simply expand their obligations.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified

local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

CSHEMA respectfully requests that NIH revise the draft consistent with these recommendations, release complete implementation materials for public review, pilot key templates and processes, and provide a minimum 24-month phased implementation period. CSHEMA welcomes continued engagement and would be pleased to assist NIH in testing implementation resources or gathering additional institutional perspectives.

Sincerely,

Robin Izzo
President
Campus Safety, Health, and Environmental Management Association

Battelle Memorial Institute, Pacific Northwest Division Response to Request for Information: Draft NIH Biosafety Policy for Research Involving Biohazards

Introduction

Battelle Memorial Institute, Pacific Northwest Division (Battelle PNWD) has operated the Department of Energy's (DOE) Pacific Northwest National Laboratory (PNNL) since 1965. PNNL's scientific discovery mission includes research that lays a foundation for innovations in 22 core capabilities, accelerating scientific discovery and positioning the U.S. for global leadership in the bioeconomy. Discovering how biological systems operate can advance energy research and the bioeconomy, generating new ways to optimize bioenergy source materials, advance biomanufacturing, and grow stronger crops. Harnessing the power of these systems can also safeguard the environment, bolster national security, and improve human health.

Conducting cutting-edge research safely has been of paramount importance to Battelle PNWD throughout its 60 years of operating experience at PNNL. As such, Battelle PNWD has rich experience in the implementation of biological safety measures. This long history and deep expertise have informed the responses, comments, and recommendations below.

Responses to Request for Information (RFI)

1. *Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed*.
    a. It is unclear what materials and research scopes require formal registration and approval versus general institutional oversight. The boundaries of what is captured under this draft policy remain fluid and unworkable. NIH should create a comprehensive, unambiguous table detailing exactly which biological materials require registration, which require full Institutional Biosafety Committee (IBC) approval, and which are exempt.
    b. The draft's definition of "toxin" is scientifically narrow, failing to clearly capture or account for high-consequence non-proteinaceous toxins (e.g., small molecule endotoxins, mycotoxins, algal toxins). NIH should expand the definition of toxins to explicitly encompass both proteinaceous and non-proteinaceous biological toxins.
    c. The current scope does not define what constitutes a "laboratory setting." It remains ambiguous whether "field work" – which lacks the physical containment controls of a traditional four-walled laboratory – has been

evaluated or included under this policy. NIH should explicitly define "laboratory setting" and clarify the policy's jurisdiction regarding field research, ecological sampling, and vector-borne pathogen fieldwork.

d. The draft lacks clarity regarding the precise threshold at which material is deemed "biological." Crucially, it fails to define the degradation endpoint – the point at which a biological agent is sufficiently broken down or inactivated to no longer be classified as biological material under this policy. NIH should insert clear, quantitative definitions establishing the baseline for what constitutes biological material, alongside validated criteria for complete inactivation/degradation where policy oversight ceases.
e. Section V mandates that risk mitigation protocols must be implemented to "lower the risks to an 'acceptable level.'" An "acceptable level" is a subjective, non-scientific phrase that cannot be uniformly enforced or audited. NIH should replace "acceptable level" with concrete, objective biosafety benchmarks (e.g., "mitigated to containment levels that prevent accidental exposure or release as validated by institutional risk assessment").
f. The draft's handling of "genetic modification" lacks specificity regarding origin, function, or source material that made the historic recombinant DNA (rDNA) guidelines highly effective. This dilution of terms creates compliance ambiguity. NIH should restore the explicit, technically precise definitions of genetic modification found in the 2024 NIH Guidelines, providing clarity regarding synthetic nucleic acids, source organisms, and functional impacts.
g. The draft policy limits the guidelines' focus to human health, omitting comprehensive protections for animal health and environmental reservoirs (e.g., agricultural plants and soils). The explicit exclusion of Genetically Modified Organisms (GMO) plants via the phrase "other than plants" creates a regulatory gap. NIH should expand the scope of its guidelines to include environmental and animal health impact assessments. NIH should replace the exclusionary phrase "other than plants" with a precise, scientifically grounded definition of the specific plant-based research parameters subject to or exempt from this policy.
h. The draft exempts or modifies review criteria for research involving "well-characterized cell lines" but fails to define the term or outline its scope. It remains unclear whether this scope is limited to common mammalian systems, or extends to insects, fish, yeast, or other eukaryotic cell models. NIH should establish a precise, scientifically valid definition of what qualifies

a cell line as "well-characterized," detailing the taxonomic boundaries and specific safety data required to achieve this status.

i. The proposed policy lacks an explicit framework governing Dual Use Research of Concern (DURC), Gain-of-Function (GOF) research, or high-consequence biosecurity parameters. Omitting these critical oversight pillars represents a severe regression from established federal biosafety standard operating procedures. NIH should integrate a clear, risk-stratified biosecurity framework that explicitly harmonizes with existing United States Government (USG) policies on DURC and enhanced Potential Pandemic Pathogens (ePPP).

j. The policy fails to recognize or regulate artificial intelligence (AI) biological design tools. Crucially, the draft provides no framework for reviewing, registering, or containing constructs where the evolutionary or biological "parent organism" has been completely obscured by algorithmic, de novo design. NIH should formulate oversight criteria specifically addressing de novo designed sequences, mandating functional risk assessments for constructs where taxonomy-based classification is impossible due to AI design.

k. The draft creates a significant biosecurity loophole by disregarding regulatory standards for DNA design, gene synthesis screening, and mass-produced synthetic libraries of gRNA/DNA. NIH should codify mandatory synthesis screening alignment protocols for institutions acquiring or producing synthetic genetic materials and guide libraries.

l. The policy is written strictly through the lens of traditional cellular biology, failing to mention or regulate cell-free translation/transcription systems. Furthermore, it completely overlooks mirror-image biology, synthetic or non-natural amino acids, and xenobiological nucleic acids (XNA). NIH should expand the definitions to account for cell-free synthesis of hazardous toxins or agents and establish clear risk boundaries for synthetic life forms utilizing non-standard genetic codes or non-natural amino acids.

m. The draft policy states, "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." However, the draft policy does not include explicit rules about how this would work or what the impact would be on other NIH-funded research at the same institution if NIH determines that the other agency does not meet NIH requirements. NIH should more explicitly

set forth guidelines for research under the regulation or purview of other federal agencies.

2. *Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).*
    a. Delegation pathways under this policy are poorly bounded. Section IV-3 permits protocol review to be "delegated to an individual or a subgroup of IBC members," and notes functions can run through "[t]he IBC, or its delegate as applicable." The draft fails to specify what qualifies an individual to approve biological research, or who holds the authority to grant that delegation. NIH should explicitly prohibit the unilateral approval of biological protocols by a single individual. NIH should define competency and credential requirements for any subcommittee or individual delegate to perform preliminary reviews on behalf of the full IBC.
    b. While the Principal Investigator (PI), Biosafety Officer (BSO), and IBC are all individually tasked with conducting risk assessments, the draft policy contains no guidance on how to integrate these assessments or resolve technical conflicts among the PI and the institutional biosafety review bodies. Furthermore, the draft policy states that "low-risk transgenes" dictate whether review delegation is permitted, but leaves "low-risk" undefined. NIH should explicitly detail the hierarchical workflow for risk assessments, establishing that the local BSO/IBC holds final authority over risk classification. NIH should provide a clear, objective definition for "low-risk" transgenes based on functional traits (e.g., non-toxigenic, non-pathogenic, replication-incompetent).
    c. The mandate that, "No research subject to this Policy may be conducted until the institution…has provided a written Biosafety Assurance through the Authorized Organizational Representative (AOR) that has been approved by NIH" will cause operational delays across the research enterprise. NIH should restructure this provision to utilize a risk-stratified approach. NIH should reserve mandatory prior NIH approval strictly for high-consequence research, such as Gain-of-Function (GOF), Dual Use Research of Concern (DURC), and Institutional Review Entity Oversight of Functional Cloning (IROFC). Standard low-to-moderate risk research should proceed under local IBC approval with routine NIH registration.
    d. Requiring institutions to "petition" the NIH to determine containment for emerging, novel, or zoonotic agents – or to lower containment for Risk Group (RG) 3 or RG4 agents – bypasses the primary function of the BSO and IBC. Local biosafety programs are fully equipped and structurally designed to perform these exact agent risk assessments. NIH should authorize the local

BSO and IBC to determine containment levels via comprehensive, documented risk assessments that consult peer-reviewed literature, historical data, and established regulatory frameworks. The NIH should provide guidance and reference criteria rather than acting as a mandatory approval bottleneck.

e. Limiting the mandatory appointment of a BSO only to institutions operating at Biosafety Level (BSL)-3/4 or working with Gene Drive Modified Organisms (GDMOs) is short-sighted. A BSO is essential for managing the foundational safety architecture to include BSL-1 and BSL-2 facilities. Furthermore, the draft policy positions the BSO as a passive auditor who merely reviews if "IBC approval conditions…are being followed," eroding the modern collaborative unit of the IBC and biosafety program. NIH should amend the policy to require a designated BSO for any institution conducting research subject to this policy, regardless of the BSL classification. NIH also should revise the language to formalize a synergistic relationship where the BSO and the IBC act as co-equal partners in developing, executing, and monitoring institutional biological risk management controls.
f. The requirement for the NIH to determine containment for emerging, novel, or zoonotic agents absent from the *Biosafety in Microbiological and Biomedical Laboratories* (BMBL) manual is infeasible. The BMBL is not exhaustive. Furthermore, the repeated use of the phrase "timely manner" regarding NIH containment reviews introduces extreme administrative vulnerability. NIH should explicitly state that the BMBL is a foundational guide, but not an all-encompassing regulatory ceiling. NIH should empower local BSOs and IBCs to utilize peer-reviewed literature to determine containment via local work planning and controls. NIH should define precise timelines (e.g., "within 15 business days of receipt") for every segment where NIH review or response is mandated.
g. The tasks outlined in Section V, V-A, and V-D represent the daily operational realities of work planning and engineering controls. These are handled dynamically by the BSO and the biosafety program, not through the episodic meeting schedule of an IBC. NIH should reassign the active oversight and validation of work planning controls to the local BSO, with retrospective or periodic oversight provided by the IBC.
h. The text in Section V-E accurately notes that Risk Groups (RGs) and BSLs are related but not equivalent, allowing containment to be adjusted higher or lower based on specific manipulations. However, this fluid risk-assessment philosophy directly contradicts the rigid, centralized NIH approval mandates

established earlier in the draft. NIH should maintain the scientifically sound logic of Section V-E. NIH should harmonize the rest of the draft policy to align with this philosophy by trusting local BSOs and IBCs to fluidly adjust BSLs up or down based on their localized, comprehensive biological risk assessments.

3. *Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).*
    a. Battelle PNWD has no comment on this RFI.
4. *Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).*
    a. Battelle PNWD has no comment on this RFI.
5. *Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.*
    a. While the provision protecting voluntarily submitted "near-miss" data from enforcement or funding actions is excellent, recommending institutions to submit this data directly to an enforcement entity like the NIH will stifle participation. NIH should restructure this framework so that near-miss and procedural data are submitted to an independent, neutral third-party scientific repository rather than the NIH directly, ensuring absolute anonymity to foster a robust culture of safety reporting.
    b. The phrase, "Any incidents involving exposures at BSL-2/ABSL-2 that require agent-specific treatment beyond basic first aid" is highly ambiguous and open to interpretations across institutions. NIH should provide clear, concrete examples of what constitutes "agent-specific treatment" versus standard medical countermeasures to ensure uniform reporting compliance.
    c. The draft policy requires that IBC meeting minutes and incident reports must be publicly posted for a minimum of five years. The draft minutes template and the draft incident reporting template require institutions to provide detailed information, yet the instructions for each form only allow redactions for private or proprietary information, without taking into account the potentially serious adverse impact to an institution's operational security from posting the required level of detail. NIH should allow institutions to redact or withhold information based on the institution's assessment of security risk, including allowing redaction of Controlled Unclassified Information (CUI) and export-controlled information. Additionally, NIH should allow biosecurity incidents to be reported through existing security channels, rather than requiring that they be posted publicly.

6. *Feedback on the implementation resources and areas in which additional guidance would be beneficial*.
    a. The text relies heavily on vague qualifiers such as "certain," "as appropriate," "as applicable," "as needed," and "as warranted" throughout the entire document. This vague terminology shifts the burden of interpretation onto institutions without providing clear criteria governing those interpretations. For example, Section III-A states, "This responsibility may be delegated to the BSO or other staff, as appropriate." The draft policy permits delegation of research compliance reviews but provides no guidance on what qualifications make delegation "appropriate." Similarly, Section IV states, "Certain research associated with higher levels of risk or uncertainty must be reviewed and approved at the Federal level by NIH." The word "certain" provides no guidance regarding what type of research must be approved by NIH. NIH should strike all subjective terms and replace them with objective criteria stating exactly when, why, and under what precise metrics an action is required or permitted.
    b. While training is mandated in the abstract, the draft provides no minimum competency standards, core curricula, evaluation metrics, or mandatory training subjects. NIH should delineate the baseline, mandatory core competencies and subject areas required for PIs, laboratory staff, and IBC members to ensure uniform training efficacy.
    c. The requirement to publicly post institutional biosafety procedures explicitly detailing BSL-3/ABSL-3 or BSL-4/ABSL-4 capabilities, alongside research with GDMOs, draws unnecessary and potentially hazardous public attention to secure facilities. NIH should strike the mandatory public listing of high-containment asset locations to protect facility security and biosecurity integrity. NIH should replace all open-ended phrasing with a specific list of required disclosures.
    d. Requiring PIs to submit initial protocols and subsequent minor modifications to both the IBC and the NIH for approval is not consistent with operational reality. It will cripple project timelines and incentivize non-compliance. NIH should re-establish that protocol review and approval is the responsibility of the PI, BSO, and/or IBC. Submission of initial and modified protocols to NIH for approval should be eliminated.
    e. The draft policy states that PIs must ensure the "integrity, maintenance, and correct functioning of facilities [and] physical containment equipment." A PI does not possess the operational authority or expertise to maintain facility HVAC systems, HEPA filtration, or structural integrity; this is an institutional

function. NIH should amend this portion of the text to state that PIs are responsible for *reporting* facility and equipment defects immediately, while the *institution* is responsible for ensuring the ongoing integrity, maintenance, and certification of facilities and engineering controls.

f. Will approvals be required only upon receipt of notice of award or as part of the grant submission process? Should institutional approval precede NIH approval?

g. The draft policy proposes that institutions submit voluntary, confidential reports regarding near misses, secondary failures, or procedural issues to the National Biosafety Data and Safety Analysis Center (NBDSAC), and states that data maintained within the NBDSAC repository will be de-identified to protect individual and institutional privacy. NIH should provide additional information about the proposed NBDSAC, including who operates it, what level of information it will be authorized to receive (CUI, classified, etc.), and whether the data in the aggregate will be reviewed for information and operational security concerns.

Conclusion

In summary, Battelle PNWD's review of the draft policy identified several general themes:

- **Reduced clarity:** While the existing *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (2024)* provide explicit, detailed definitions and clear boundaries for institutional oversight, the draft policy shifts away from regulatory precision. Rather than enhancing biological safety, this draft introduces systemic ambiguity, structural loopholes, and phrasing that leaves compliance obligations open to interpretation by each research institution.
- **Risk of systemic delays:** Multiple provisions requiring direct NIH review and approval for standard oversight mechanisms (e.g., Biosafety Assurances, containment downgrades) will create severe administrative bottlenecks, delaying or even preventing research of national importance. These requirements fail to leverage the existing infrastructure of local Institutional Biosafety Committees (IBCs) and Biosafety Officers (BSOs).
- **Erosion of local authority:** The draft policy consistently shifts the responsibility of risk assessment and containment determination away from local Subject Matter Experts (SMEs)—specifically BSOs and IBCs—and centralizes it within the NIH. This undermines the established principle of institutional self-governance via local peer review.
- **Omission of frontier biotechnologies:** The draft policy fails to account for cutting-edge technologies, completely omitting regulatory frameworks for AI-generated biological design, synthetic DNA screening, cell-free systems, and non-natural/mirror-image biology.

NIH should revise the draft policy to provide more clarity, consistency, and forward thinking while preserving institutional self-governance and process efficiency to safely advance necessary, groundbreaking research.

Battelle PNWD appreciates the opportunity to provide these comments and recommendations.

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Bacteriology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Since the questions asked are different, our IBC has always used the RGs run the Guidelines as they pertain to recombinant work, but defer to the BMBL for assessment for non-recombinant work.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft states "Institutions must report to NIH incidents involving…. any incident at BSL/ABSL-3 or BSL/ABSL-4 (including
potential exposures)". "Any incident" seems too broad and ill-defined. What does this mean, beyond potential exposures or overt exposures?

The draft states "Delete NIH incident reports for incidents at BSL-1/ABSL-1, BSL-2/ABSL-2 that do not involve agent-specific medical treatment when first aid is administered". I'm not sure that it will be possible to determine what specific treatments the person received due to HIPAA restrictions.

6. Other feedback relevant to this resource: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1 Clarify which genetically modified materials require full IBC review. The proposed language for “genetically modified cells, viruses, or organisms” is too broad without definitions or examples, especially for “certain vectors, replicons, gene drive modified biological agents, GDMOs”. NIH should provide clear risk-based criteria, so routine low-risk molecular biology, standard non-replicating vectors, or established low-risk systems are not unnecessarily routed to full committee review.

2. Exempt low-risk, non-replicating synthetic nucleic acids, synthetic oligonucleotides, and certain transgenic animals from registration unless they encode hazardous products. The Policy should explicitly exempt low-risk, non-replicating synthetic nucleic acids and synthetic oligonucleotides, as well as transgenic animals maintained at BSL-1/ABSL-1, from IBC registration. Transgenic animals should qualify for the exemption only when genetic modification does not encode a hazardous product or otherwise meaningfully increase biosafety, occupational health, animal, environmental, or public health risk. Requiring registration for very low-risk nucleic acids and modified animal models creates unnecessary administrative work for investigators and compliance offices, including repeated alignment and amendment of IBC and IACUC protocols, without a corresponding biosafety benefit.

3. Define which toxins are within the scope of the Policy. The current NIH Guidelines define toxins within scope as those having an LD50 of less than 100 ng/kg. The draft NIH Biosafety Policy does not establish a potency threshold or otherwise define which toxins are covered, creating uncertainty about which proteins require IBC approval before use.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support the Policy’s risk-based approach, including the option for delegated review of low-risk research.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1. Balance transparency with biosecurity. NIH should require institutional accountability without mandating public disclosure of sensitive technical details. Institutions should retain complete IBC minutes and incident records for NIH or other authorized oversight bodies, while public summaries should provide non-sensitive information sufficient to demonstrate oversight.

2. Reduce the detail required in the NIH IBC meeting-minutes template. The template should support concise public summaries without requiring agent-specific methods, facility vulnerabilities, security-sensitive deliberations, detailed incident narratives, or construct details. Even when this information is not proprietary, publicly posting it could reveal researchers planned work to competitors worldwide before the research begins.

3. Incident reporting and public posting of minutes may have unintended consequences: PIs and other personnel may be less likely to report incidents if they know the information could be posted publicly on the institution's website. In some cases, identifying the PI and agent involved could allow readers to figure out who the person is in an exposure or infection report, creating potential privacy concerns. There is also concern from an IACUC perspective of releasing animal care-related details into public forum (relevant for both minutes and incident reports). A more appropriate approach would be to report incidents to NIH, which could aggregate and evaluate the information and publish de-identified reports for the public.

4. Define which inspection findings must be reported. NIH should provide clear, risk-based criteria and examples distinguishing reportable findings from routine deficiencies that institutions can correct through normal follow-up. Guidance should address common findings such as missed eyewash inspections, incomplete personal protective equipment use, training lapses, documentation deficiencies, equipment certification issues, and containment failures. Reporting should focus on findings that present a significant or unresolved risk to personnel, the environment, or public health rather than minor issues that are promptly corrected.

6. Other feedback relevant to this resource: 1. Provide examples and exemptions to support consistent implementation. Practical examples would help institutions distinguish among activities requiring full IBC review, delegated review, registration, or no registration. NIH should address common areas of uncertainty, including viral vectors, replicons, genetically modified cells, low-risk transgenic animals, and low-risk recombinant or synthetic nucleic acid research (for example, overexpression plasmids encoding nonhazardous human proteins). Requiring IBC review for every nonhazardous gene or construct would add work for investigators, biosafety offices, and IBCs without improving biosafety.

2. Clarify transition requirements for protocols approved for more than three years. NIH should explain how the new Policy applies to active protocols with approval periods that extend beyond the proposed three-year limit. Institutions need to know whether these protocols must undergo renewed review by the Policy's implementation date, be reviewed within three years after that date, or remain approved until their current expiration dates. NIH should also clarify how institutions should handle active

protocols involving agents that were previously exempt from IBC registration. Clear transition requirements and a reasonable implementation period are needed to ensure consistent compliance and avoid unnecessary disruption of ongoing research.

3. Provide practical tools and examples for conducting appropriate risk assessments. Institutions establishing new IBCs may have limited experience conducting in-depth risk assessments or may not have systems for collecting the necessary information from PIs. NIH should provide risk-assessment templates, examples, and training resources to help these institutions develop consistent processes and prepare new IBC members to conduct appropriate reviews.

4. Allow sufficient time for approval of Institutional Assurances before Policy implementation. Institutions that were not previously required to register an IBC may need to establish institutional policies and procedures, create a new committee structure, develop systems to collect the required information, prepare an Institutional Assurance, and obtain NIH approval. Completing these steps within the six months between Policy finalization and implementation would be extremely difficult. The same timeline may also be challenging for established institutions whose IBCs already review recombinant and wild-type agents. NIH should provide an implementation period that reflects the time required for institutions to establish or revise these systems and obtain approval (at least 1-2 years).

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Draft NIH Biosafety Policy for Research Involving Biohazards, NOT-OD-26-112, contains a nonscientific definition of "genetic modification". Specifically, the definition of "genetic modification" includes: "The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria: ..." One of the criteria listed is "Can be transcribed or translated." This is utter nonsense. For example, transient transfection into mammalian cells of a plasmid encoding the protein Green Fluorescent Protein (GFP) would be considered a genetic modification, even though both the plasmid and the resulting GFP protein will disappear from the cells or organism in a matter of days. There is no permanent change to the genome of the cells or organisms in this case. Even with selective pressure such as antibiotics, removal of the selective pressure will lead to loss of the plasmid over a short period of time, again days. The proper definition of "genetic modification" must include a permanent change to the genome of the cells, organisms, or viruses. The definition in NOT-OD-26-112 goes against decades of understanding of molecular biology.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Given the improper definition of "genetic modification" as described in answer 1, the utility of Risk Groups will be compromised.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definition of genetic modification is incorrect. The use of 'can be transcribed or translated' will incorrectly include therapeutic modalities that have nothing to do with genetic modification such as mRNA, saRNA, and episomal DNA.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

Date:	October 19, 2026
To:	Office of Science Policy National Institutes of Health 6705 Rockledge Drive, Suite 750, Bethesda, MD 20892
Submission Portal:	Submitted via NIH OSP Electronic Comment Portal
Subject / Notice:	Formal Public Comments and Recommendations on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice Number: NOT-OD-26-112)

ABSA International, the Association for Biosafety and Biosecurity, is a nonprofit professional association representing biosafety and biosecurity professionals in the United States and internationally. Our membership spans academic and research institutions, government laboratories, biotechnology companies, healthcare organizations, public health agencies, and consulting practices. Members bring scientific, technical, operational, and regulatory expertise across diverse biological research and laboratory settings.

ABSA's comments reflect the practical experience of professionals responsible for translating biosafety policy into daily practice. Our members conduct risk assessments, support Institutional Biosafety Committees (IBCs), develop training and containment practices, investigate incidents, and advise institutions on compliance. They understand how policy requirements affect laboratory safety, reporting culture, institutional resources, and the conduct of research.

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public

confidence in NIH-supported science. ABSA supports NIH's efforts to strengthen biosafety oversight. We offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

***Topic to Address**: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:

    a. the nature and stability of the genomic modification;

    b. whether the modification is heritable and the potential for transmission through breeding;

    c. effects on animal health, phenotype, host range, susceptibility, or disease;

    d. potential entry into breeding or food-production systems;

    e. potential environmental release or interaction with non-research animal populations;

    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and

    g. applicable federal, state, or other regulatory oversight.

2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

  Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

ABSA International believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, ABSA International requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, ABSA International welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. ABSA International does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. ABSA International recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, ABSA International recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with ABSA's earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. ABSA International recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, ABSA International kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. ABSA International encourages NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While ABSA supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: ABSA recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Reference basis: Draft NIH Biosafety Policy, Section V-E; NOT-OD-26-112 implementation-resource statement. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7, and Appendix G-II-C-5.

263. Upstate Biosafety, LLC

I am responding: On behalf of an organization

Name: David Pawlowski

Name of Organization: Upstate Biosafety, LLC

Type of Organization: Commercial Entity (Biotech/Device/Pharmaceutical Company/Small Business)

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biosafety Consulting

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of this policy is appropriate and will align most IBCs with what is already happening at many institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered oversight is appropriate and gives local IBCs freedom to set research oversight using their own risk assessments.

3. Continued utility of Risk Groups: The use of Risk Groups is preferred and allows for oversight based on risk assessment, Risk grouping, procedures, engineering controls, and staff proficiency.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I'm happy that a statement on voluntary compliance was included.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: See attached document for specific comments. Imperative to the reporting template, names should be removed as this will harm the open culture of safety that is being developed throughout so many institutions.

6. Other feedback relevant to this resource: see attached document

Upstate Biosafety, LLC Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Notice NOT-OD-26-112 ·

The Modernization of the NIH guidelines is well a supported effort. The draft NIH Biosafety policy is a well written document that places local risk assessment to the forefront of the policy, which is a very welcome aspect of the document. I very much appreciate all of the effort that has gone into creating this draft, especially the regional listening sessions and the ability to comment on the policy prior to its adoption. Please accept the comments below for thoughtful revision of this exciting draft policy.

High-priority comments

Draft policy

ID	Section / item	Comment	Suggested change
P-001	Section II - Scope	The draft includes "Research conducted with transgenic organisms at BSL-1/ABSL-1", which may be interpreted as any research with transgenic rodents for example including breeding.	Clarify the scope of research with established transgenic rodents and other animals
P-002	Section II - Scope	Novel agent or organism: An agent or organism not existing in nature, deliberately designed, and possibly derived from multiple, different natural or synthetic sources (e.g., chimeras, or organisms generated by synthetic biology in conjunction with artificial intelligence).	Clarify if this means reviewing the software or how the AI is used. Prepare tools and guidance on how to review AI. With AI, there are no organisms, physical infrastructure ext. Provide guidance on how institutions audit this area of research.
P-003	Section II - Scope	Creating a de novo biosafety registration every three years creates an administrative burden and diverts resources.	Recommend a triennial review, thus aligning with IACUC and IRB rules.
P-004	Section II - Scope	The scope of "self-aggregating proteins" needs to be clarified. Does this mean misfolded, self-aggregating proteins or all self-aggregating proteins that are normal biology?	Clarify for “hazardous” self-aggregating proteins versus “all” self-aggregating proteins
P-005	Section II - Scope	The definition of cells, viruses, or organisms that have been genetically modified does not clearly indicate if breeding of transgenic rodents, (previously exempt) is now covered by the new policy	Clearly define if breeding of previously exempt transgenic animals is still exempt
P-006	Section II - Scope	The existing scope of NIH Guidelines extends to clinical trials conducted with gene transfer products produced with NIH funding. For example, when an academic medical center develops a product with NIH funding, a clinical trial of that product may	The current scope of applicability for clinical trials as long as research collaboration or contractual agreements exist should be preserved for any new policy. Licensing of a product or technology to a business entity should not abrogate biosafety requirements.

ID	Section / item	Comment	Suggested change
		be conducted at the originating institution and also at community clinics. Under current rules such clinical trials require IBC oversight at all locations in the USA as long as research collaboration or contractual agreements apply. This means that staff, visitors, and the public near the community site have equal and equitable protection of IBC oversight compared to staff and visitors at the academic medical center.	
P-007	Section II - Scope	The Draft Policy proposes that research "also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained" This sentence could be construed to limit the scope of the Draft Policy to the point of irrelevancy. There are innumerable federal agencies and any research in the USA is also under the regulation or purview of multiple agencies such as OSHA, EPA, CDC, and / or EEOC.	Simply being under purview of multiple agencies should not exempt research from IBC oversight.
P-008	Section II Scope	As written, the definition of "research involving biohazards" provided under Scope does not make it clear that the "potential risk to human health" is from the biohazardous materials by saying "involving known or potential risk to human health AND any of the following....". Technically, the potential risk to human health could be from a chemical or radiological hazard using this definition.	One option to address this would be to replace "and any of the following" with "attributed to any of the following". However, the term "Biohazard" should be clearly defined under General Definitions.
P-009	Section II - Scope	The draft defines biohazards primarily in terms of risks to human health, which may exclude biological agents that pose significant risks to animal health, plant health, agriculture, or the environment. This may create gaps compared with the current NIH Guidelines.	Clarify whether animal, plant, agricultural, and environmental biohazards are within the scope of the Policy. If they are intentionally excluded, clearly state this and explain how the existing plant and environmental biosafety provisions of the NIH Guidelines will be addressed under the new framework.
P-010	Section II - Scope	The inclusion of "clinical settings" within laboratory research creates uncertainty as to whether routine collection of human biospecimens for research, such as venipuncture, requires IBC oversight even when no biohazard is manipulated or administered.	Clarify that routine clinical specimen collection alone does or does not require IBC review solely because specimens are collected for research. Subsequent handling or manipulation of the specimens should be evaluated separately based on the associated biosafety risk.
P-011	Section II - Scope	The definition of "biomedical research in laboratory settings" does not clearly address biosafety-relevant field research or non-research biological activities, such as	Clarify that field research involving meaningful biological exposure risks, such as wildlife handling or sampling with potential zoonotic hazards, should receive appropriate

ID	Section / item	Comment	Suggested change
		teaching laboratories in academic institutions. This may create both gaps in oversight and unnecessary expansion of IBC requirements.	risk-based biosafety oversight. Conversely, clarify if teaching laboratories and other non-research activities should be subject to the Policy.
P-012	Section II - Scope	The proposed six-month implementation period may be insufficient given the substantial changes in institutional responsibilities, oversight processes, training, procedures, and compliance systems required by the new Policy.	Provide at least 12 months between publication of the final Policy and its effective date to allow institutions sufficient time for effective and consistent implementation.
P-013	Section II - Scope	Clarify if "clinical settings" includes routine pathology lab work where the data collected from clinical specimens (e.g. bacterial cultures, etc.) will be analyzed for research. As written, virtually all clinical pathology laboratories which contribute to research would now require IBC oversight.	Specify that [certified, accredited, etc.] clinical laboratories which contribute to research through performing routine procedures are not subject to IBC oversight.
P-014	Section II - Scope	The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition.	Distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.
P-015	Section II - General definitions	On the proposed definition of Genetic Modification, with regard to passaging for example this would encompass almost all cell biology. Any passaged cell in cell culture will undergo some stable alteration, albeit non-deliberate and non-targeted.	The definition of Genetic Modification can be limited to deliberate modifications including passage under one or more selective pressures.
P-016	Section II - General definitions	The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. The draft also refers to gene drive modified organisms, gene drive modified biological agents, and GDMOs without reconciling the terms.	Biological agent definition in 18 USC 178 (1) should be consistent throughout all government documents
P-017	Section II - General definitions	The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk.	Distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis, and assign oversight based on the resulting or expected phenotype and risk.

ID	Section / item	Comment	Suggested change
P-018	Section III-A - Responsibilities of the Institution	The Policy does not clearly define what constitutes an adequate OHSP for research subject to the Policy or how institutions should determine and document that the OHSP appropriately addresses the relevant research risks.	Clarify that an existing institutional OHSP may satisfy the Policy if it appropriately covers the applicable research and associated hazards. NIH should also provide criteria or guidance for institutions to assess, review, and document the adequacy of occupational health support for research subject to the Policy.
P-019	Section III-A - Responsibilities of the Institution	Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for the researchers involved, where identification, even generally, could put their personal safety at risk.	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries focused on oversight outcomes, corrective actions, and lessons learned. Detailed records would remain available to NIH for oversight and through existing lawful disclosure processes.
P-020	Section III-A - Responsibilities of the Institution	Biosafety Assurance approval is required before covered research can continue, and NIH review may not be complete on the effective date.	Provide a transition mechanism for Biosafety Assurance approval, such as provisional or deemed assurance, so ongoing covered research is not halted because NIH review is incomplete on the effective date.
P-021	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The term "release" needs to be better defined involving facility and/or equipment failures. This term has caused confusion in the past, is this term being defined as a breach in primary containment, or otherwise?	Better define or change term "release" to change to true intent of meaning, whether that be a breach or primary containment or otherwise
P-022	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Criteria for determining a "potential laboratory-acquired infection" under the report requirements are not provided.	Provide specific criteria for what would be considered a "potential laboratory acquired infection" or revise to limit the reporting requirement to confirmed laboratory-acquired infections through diagnostic testing given the time sensitive reporting requirement for 24 hours.
P-023	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The reporting expectations for "compliance violations" at any BSL/ABSL is vague and open ended. This reporting expectation needs to be specific to avoid over reporting of minor compliance issues.	Revise the compliance violation reporting statement to be specific as follows: The following compliance violations associated with this policy at any BSL/ABSL/ACL: 1) Failure to obtain or maintain IBC approval; or 2) Failure to obtain NIH approval for lowering biocontainment for research, when required.
P-024	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The expectation to include or have access to an individual knowledgeable in “community attitudes” appears to overlap with the required unaffiliated IBC members, who are specifically appointed to represent	Clarify whether the required unaffiliated community members ordinarily satisfy the “community attitudes” expectation, or whether NIH intends this to represent a

ID	Section / item	Comment	Suggested change
		the interests of the surrounding community.	separate area of expertise requiring an additional member or ad hoc consultant.
P-025	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft primarily describes the BSO through operational and technical duties and does not fully reflect the BSO's broader role in institutional biosafety governance. It also does not clearly address the authority, leadership access, and resources necessary for the BSO to effectively fulfill these responsibilities.	Define the BSO as the institution's designated biosafety professional responsible for leading or administering the biosafety program and providing technical oversight. Require appropriate authority, access to institutional leadership, and resources, and clarify that operational functions may be delegated to qualified biosafety professionals under the BSO's direction or supervision.
P-026	Section III -B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft does not require a BSO unless a certain biosafety level of research is occurring. This can create an undue burden on already stretched faculty and/or a conflict of interest	Consider the following; all R1 Universities should have a full-time professional BSO.
P-027	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The policy expands BSO and IBC responsibilities without defining corresponding authority.	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support: access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary. Specify the authority, independence, and access expected for a BSO or alternate official performing BSO duties.
P-028	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft ties public posting of final incident reports to NIH's "final response," but does not define an endpoint for that response, so institutions could be held to a posting deadline that depends on an open-ended federal review. The draft also does not state what may be redacted.	Establish a defined endpoint for NIH's "final response." If public posting is retained, define allowable and required redactions, including PI names, grant identifiers, and other information needed to protect proprietary and security-sensitive information, and replace detailed public disclosures with de-identified summaries wherever possible.
P-029	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The incident reporting categories overlap and use undefined terms. It is unclear whether precautionary post-exposure prophylactic treatment is "agent-specific treatment," whether any event at BSL-3 or BSL-4 is reportable regardless of its relevance to biohazard containment, and how administrative noncompliance differs from events presenting an actual biosafety risk.	Define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." Clarify the points above, and do not require a 24-hour reporting timeframe for administrative noncompliance and other low-risk items.
P-030	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Requiring every internally reviewed minor event to be publicly posted with unredacted identifying information would undercut local management of lower-risk events and near misses.	Preserve local management of lower-risk events: institutions should retain authority to manage lower-risk events and near misses through local IBC review systems. Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events,

ID	Section / item	Comment	Suggested change
			minor spills, and compliance violations that do not present a meaningful safety risk.
P-031	Section III-D - Responsibilities of the National Institutes of Health (NIH)	The draft anticipates NIH publication of approved lower-containment determinations but does not state whether another institution may rely on them.	Create a searchable national determination and risk-classification database. Define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies, so that a prior NIH containment determination may be used by another institution without a new petition.
P-032	Section III-D - Responsibilities of the National Institutes of Health (NIH)	Public posting of incident report information may inadvertently allow identification of the individual(s) involved, potentially violating federal rules on disclosure of medical information. A national system is only useful if its boundaries are clear and if institutions and researchers trust that voluntary submissions will not be used for enforcement.	Develop a confidential, de-identified national reporting system that supports trend analysis and shared learning, preserves confidential near-miss reporting, and states that voluntary submissions will not be used for enforcement. Publish annual de-identified summaries, trends, contributing factors, and lessons learned, without attaching names or institutions to routine, well-managed incidents.
P-033	Section IV - Categories of Oversight for Research Based on Risk	The policy is unclear regarding review of synthetic/recombinant DNA. Research with plasmids or viral vectors appears to be covered under IV-3, but synthetic nucleic acids do not appear to be covered in the new policy.	Better define research with synthetic nucleic acids
P-034	Section IV-1 - Research That Requires NIH and IBC Approval Before Initiation	Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently handled routinely at both BL1 and BL2, for example organisms discovered during environmental screens.	Define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.
P-035	Section IV-2 - Research That Requires IBC Review and Approval Before Initiation	For clinical research, "capable of shedding" is very vague. Is shedding assumed unless there is evidence otherwise? Must the evidence be agent-specific (those data usually don't exist), or can it be categorical? What constitutes shedding - viable agent or identifiable fragments (many studies only use PCR to look for fragments)? The scope will vary dramatically based on those answers.	Clarify criteria for what constitutes shedding under the intent of the Policy.
P-036	Section V-A - Requirements and Considerations for Risk Assessment of the Characteristics of the Biohazard	The statement under Section V-A that "Biological agents that cause disease in humans are classified into four RGs based on pathogen characteristics and population impacts." is incorrect. The current definition of risk groups in the NIH	Revise the statement "Biological agents that cause disease in humans are classified into four RGs based on pathogen characteristics and population impacts." to reflect NIH's revised classification system for effectively characterizing societal risk vs. worker risk.

ID	Section / item	Comment	Suggested change
		Guidelines provides no reference to community risk or population impact. Although the WHO definition of risk groups does make an effort to include community risk, the relative community risk assigned to each risk-group does not adequately capture the large variations in community/population risk that exists at each human health-based RG category. For example, Appendix G of the NIH Guidelines defines BSL-3 enhanced requirements for specific RG3 influenza viruses based largely on their pandemic potential, which is not at all consistent with the WHO RG3 characterization of community risk as "low community hazard" and "does not ordinarily spread from one individual to another". Given this important discrepancy between risk group classifications and societal risks, NIH needs to consider creating a separate, distinct risk classification nomenclature specific to relative societal risk.	
P-037	Section V-D - Requirements and Considerations for Risk Assessment of Manipulations of Biohazards	The Policy identifies “large culture volumes” as a factor that may increase risk but does not define what constitutes a large volume or when additional large-scale risk assessment is expected.	Define a threshold or clear criteria for identifying large-volume culture research based on organism and procedural risk.
P-038	Section V-E - Risk Mitigation Strategies and Laboratory Containment	The requirement for conducting experiments with viruses containing genes from RG3 influenza viruses with pandemic potential at BSL-3 enhanced containment with the additional requirement for an occupational health plan does not specify the detailed expectations of the minimum BSL-3 enhanced requirements. The Background section of the policy does note that additional information about requirements for containment practices, occupational health plans, and training for research with RG3 influenza viruses (currently articulated in Section II-D-7 and Appendix G-II-C-5 of the NIH Guidelines) will be shared with the research community through implementation resources. However, there needs to be a clear minimum set of requirements when it comes to BSL-3 enhanced expectations for RG3 influenza viruses and other pathogens with potential for significant societal consequence. These expectations should be the default mitigation measures unless a specific element is determined to be	Ensure that the BSL-3 enhanced mitigation measures planned to be included in the implementation resources serve as the default requirements for BSL-3 enhanced for RG3 influenza viruses and other communicable pathogens with potential for significant societal consequence, unless otherwise determined to be unnecessary by the local IBC in consultation with NIH.

ID	Section / item	Comment	Suggested change
		unnecessary based on the IBC risk assessment of the agent and protocols involved.	
P-039	Section V-E - Risk Mitigation Strategies and Laboratory Containment	The draft requires BSL-3 enhanced containment and an occupational health plan for specified influenza research but does not define the minimum requirements for either, creating uncertainty in implementation and compliance.	Define the minimum requirements for BSL-3 enhanced containment and the influenza-specific occupational health plan or directly reference applicable implementation guidance. Also clarify how the required occupational health plan relates to the institution's broader occupational health and safety program.
P-040	Other Comments	The Policy relies heavily on headings and bullet points, making specific provisions difficult to cite and cross-reference consistently	Adopt a consistent hierarchical numbering system and assign each substantive requirement a stable, unique citation identifier (e.g., III.B.2.a.(1))
P-041	Other Comments	The policy does not define a location for responsibility. Are tenants of a location the responsibility of the IBC serving that location or are tenants responsible for obtaining IBC support elsewhere.	Define who is responsible for oversight in leased space situations.

Draft incident reporting template

ID	Section / item	Comment	Suggested change
I-001	Part 1. Institutional Information	All reports for incidents must be posted on a public-facing webpage of the institution.	**Suggestion 1:** A strong safety culture depends on researchers feeling comfortable with reporting incidents, near misses, and unsafe conditions without fear the report will be considered punitive. Public posting of incidents could lead to fear that the report could be used to blame labs and create a negative mind set, leading labs to be more reluctant to report incidents. **Suggestion 2:** Many incidents that would fall under this are minor, and posting everything would not serve the public interest and would dilute attention from potentially significant incidents. For example, incidents involving noninfected lab mice are categorically different than incidents involving pathogen cultures.
I-002	Other Comments	The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially violating federal rules on disclosure of medical information.	**Revise the template and posting requirements so that required fields cannot identify the individuals involved; use de-identified, aggregate public reporting (see P-102).**

Medium priority comments (41)

Draft policy (35)

ID	Section / item	Comment	Suggested change
P-042	Section II - Scope	Definition for Synthetic Nucleic Acids is missing	Add the definition of SNA used in the current NIH Guidelines: nucleic acid molecules that are chemically or by other means synthesized or amplified, including those that are chemically or otherwise modified but can base pair with naturally occurring nucleic acid molecules (mRNA, miRNA)
P-043	Section II - Scope	Work with genetically modified arthropods is not presented in the scope section	Add example to "Cells, viruses, or organisms (for example arthropods), other than plants, that have been genetically modified;
P-044	Section II Scope	It's not clear what is meant by the statement, "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained."	Revise statement to say, "once approvals or other applicable clearances have been obtained from that agency."
P-045	Section II - Scope	The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBCs responsibility for environmental risk and references animal and plant health requirements in other contexts.	Explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. Explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.
P-046	Section II - Scope	The draft does not say how the Policy applies to research with existing IBC approvals. For example, some organisms have no risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.	Define a process for managing research with existing IBC approvals, including organisms without a BMBL risk group or containment recommendation for which the IBC has already assigned containment.
P-047	Section II - General definitions	Arthropod Containment Levels are not captured in the scope of this policy.	Revised the definition of laboratory research to include arthropod containment
P-048	Section II - General definitions	“Biomedical research” appears to be tied to whether the activity occurs at an NIH-funded institution rather than to the nature and purpose of the activity. Clinical research involving biohazards is also forced into a laboratory setting described by BSL or ABSL terminology.	Consider defining “biomedical research” by the nature and purpose of the activity, and address applicability to non-NIH-funded research at recipient institutions separately. Define clinical research involving biohazards independently of BSL/ABSL laboratory terminology.
P-049	Section III-A - Responsibilities of the Institution	Occupational health requirements lack clear triggers, assigned authorities, and	Include clear triggers, assigned authorities, and responsibility for developing and

ID	Section / item	Comment	Suggested change
		responsibility for developing and communicating required procedures.	communicating required occupational health procedures.
P-050	Section III-A - Responsibilities of the Institution	Retention and public-availability requirements differ by record type and award, and the draft does not map them.	Include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. For each, identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.
P-051	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The categories of NIH reportable incidents listed may have the "potential" to pose a significant risk to human health, but it is misleading to say they pose a significant risk to human health and could suggest to the public that these reported incidents are riskier than they actually are.	Replace the wording "that pose a significant risk to human health: with have the potential for significant risk to human health" in both the policy and on the incident report form.
P-052	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The wording of the BSL-3/ABSL-3 and BSL-4/ABSL-4 reporting requirement for "potential exposures" should be modified to align with the definition of "occupational exposure" in the select agent regulations for consistency and to eliminate any uncertainty related to potential exposure vs. occupational exposure requiring reporting.	Revise the "exposure" reporting requirement for BSL-3/ABSL-3 and BSL-4/ABSL-4 to read as follows: Any occupational exposure defined as any reasonably anticipated skin, eye, mucous membrane, parenteral contact, or respiratory aerosol exposure to pathogens at BSL-3/ABSL-3/ACL-3 or BSL-4/ABSL-4 that may result from the performance of an employee's duties. Any exposure event that results in the activation of post-exposure medical treatment or surveillance protocols would be considered an occupational exposure. To simplify, the definition of "occupational exposure" could be added to the General Definitions section so that the statement here could be "Any occupational exposure."
P-053	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The wording of the BSL-3/ABSL-3 and BSL-4/ABSL-4 reporting requirement for releases should be modified to align with the definition of "release" in the select agent regulations for consistency and to eliminate any uncertainty related to "potential releases vs. releases that need to be reported.	Revise the BSL-3/ABSL-3 and BSL-4/ABSL-4 "release" reporting requirement to read as follows: Any release defined as any discharge of a BSL-3/ABSL-3/ACL-3 or BSL-4/ABSL-4 pathogen outside primary containment devices (e.g., biological safety cabinets, centrifuge safety cups, etc.) or secondary barriers (e.g., HEPA exhaust systems and other biocontainment facility boundaries). If the definition of "release" is moved to the General Definitions section, the policy can simply say "Any release" under the reporting section.
P-054	Section III-B - Responsibilities of the Institutional	The wording of BSL-2/ABSL-2 exposure reporting requirements should be aligned with the proposed definition of occupational exposure for BLS-3/ABSL-	Revise the BSL-2/ABSL-2 exposure reporting requirement to read as follows: Any incidents involving occupational exposures at BSL-2/ABSL-2/ACL-3 that require agent-specific

ID	Section / item	Comment	Suggested change
	Biosafety Committee (IBC)	3/ACL-3 and BSL-4/ABSL-4 exposure reporting.	post exposure medical treatment beyond basic first aid.
P-055	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The wording of the reporting exemption for minor spills of low-risk agents should be revised to clarify that the breach in containment is at the laboratory level and does not involve potential for community risk.	Revise the wording of the reporting exemption for minor spills of low-risk agents as follows: "Minor spills of low-risk agents, that do not involve a break of laboratory containment with potential for community risk, and that were properly cleaned and decontaminated, generally do not need to be reported."
P-056	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The wording of the incident report posting requirement should be revised to clarify that only NIH incident reports need to be posted on a public-facing webpage, not "all incident reports".	Revise the wording of the first sentence of the incident report posting requirement to read as follows: "Posting all NIH incident reports on a public-facing webpage on the website of the institution, using the incident reporting template."
P-057	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The 24 hour reporting requirement will be difficult to meet for any reportable incidents that occur on a Friday.	Replace the 24 hour reporting requirement with "(by the close of the next business day or as soon as the institution becomes aware of the incident)"
P-058	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The statement that minor spills of low-risk agents “generally do not need to be reported” does not specify whether this refers to reporting to NIH, the IBC, or both.	Clarify the applicable reporting level and distinguish between institutional/IBC reporting and external reporting to NIH.
P-059	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft allows recused members to count toward a quorum and does not specify the quorum or voting denominator, remote participation, or the use of ad hoc consultants. Some institutions will also have difficulty recruiting unaffiliated members.	A member recused because of a conflict should not count toward the quorum needed for action on that matter. Specify the quorum and voting denominator after recusal, expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.
P-060	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	Requirements for unaffiliated members and specialized expertise may be unworkable in small, rural, geographically isolated, or institution-dominated communities.	Expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Keep requirements for unaffiliated members and specialized expertise flexible while preserving meaningful independent input.
P-061	Section III-C - Responsibilities of the Principal Investigator (PI)	The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance.	Allocate responsibility for facilities and containment equipment among the institution, program leadership, facilities owner, BSO, PI, and equipment user.
P-062	Section III-D - Responsibilities of the National	How will the term "in a timely manner" be defined?	Define time range of the term "timely manner."

ID	Section / item	Comment	Suggested change
	Institutes of Health (NIH)		
P-063	Section IV-3 - Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members	Delegated review is a welcome modernization, but requiring every approval to be reported "in full" at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. The full committee's role after delegated approval is not defined.	Permit institutions to provide a concise approval log or aggregate report to the IBC, with records retained for audit. Define the full committee's role after delegated approval.
P-064	Section V-A - Requirements and Considerations for Risk Assessment of the Characteristics of the Biohazard	Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level.	Retain Risk Groups as a starting point and preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.
P-065	Section V-E - Risk Mitigation Strategies and Laboratory Containment	A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems.	Allow equivalent risk-based containment and provide technology-specific guidance.
P-066	Section V-E - Risk Mitigation Strategies and Laboratory Containment	The influenza language could apply to any construct containing any listed segment and does not specify what triggers BSL-3 enhanced containment.	Specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment.
P-067	Other Comments	Because of uncertainty in the final requirements, and given the expansion of institutional scope, review, documentation, public-posting, assurance, and reporting obligations, institutions cannot fully assess the burden or feasibility of the final policy.	Provide an opportunity for public review and comment on the next draft of the policy, and on the complete implementation materials, before the policy is finalized.

Draft incident reporting template (3)

ID	Section / item	Comment	Suggested change
I-003	Part 1. Institutional Information	"Incident reports should not include any personally identifiable identification of individuals involved in the incident (aside from the Principal Investigator's name)."	Remove reference to any names and other personal identifiable information
I-004	Other Comments	Is the National Biosafety Data and Safety Analysis Center (NBDSAC) subject to FOIA?	Clarify how confidentiality is going to be maintained in light of FOIA
I-005	Other Comments	Institutions have differing needs, and a single fixed template may not suit all of them.	Allow flexible templates to account for institutional needs.

Draft IBC meeting minutes template (3)

ID	Section / item	Comment	Suggested change
M-001	Other Comments	The meeting minutes template does not clearly distinguish among full IBC review, delegated review, and periodic/renewal review. If a notification/registration-only category is adopted, this should also be reflected in the template	Add separate or clearly identified categories for full IBC review, delegated review, and notification/registration-only activities, with documentation proportional to the level of oversight. Clarify that periodic/three-year reviews may use the same format as new registrations if they are conducted as de novo reviews.

Low priority comments (12)

Draft policy (8)

ID	Section / item	Comment	Suggested change
P-068	Section II - Scope	Extending the scope to include wild-type biological agents, as proposed, is a good idea.	—
P-069	Section II - General definitions	Inclusion of reassortment (especially with regard to influenza viruses) as form of genetic modification will be an improvement over current NIH Guidelines.	—
P-070	Section II General Definitions	The acronym GDMO is used throughout the body of the policy but never defined. Only Gene Drive is defined.	Add Gene Drive Modified Organism (GDMO) to the definitions sections and provide an appropriate definition to supplement the existing definitions provided for Gene Drive and Genetic modification.
P-071	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The responsibility described for the 6th bullet unnecessarily repeats part of the 5th bullet.	Revise the first sentence of the 6th bullet as follows: Petitioning NIH to lower the minimum containment for research involving RG3 and RG4 agents that have not previously been approved by NIH.
P-072	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The BSL-3/ABSL-3 and BSL-4/ABSL-4 reporting expectations for biological agents inventories should use terminology consistent with the select agent program for consistency to avoid uncertainty on what needs to be reported.	Replace the biological agent reporting wording as follows: Theft or loss of biological agents that may have public health consequences.
P-073	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The wording of the BSO's duties should be revised to clarify that the scope for conducting periodic inspections includes all BSL/ABSL/ACL research activities.	Revise the wording of the first bullet under BSO's duties as follows: "Conduct periodic inspections at all BSL/ABSL/ACL laboratories to ensure that laboratory biocontainment facilities and equipment are functioning properly, biosafety standards are rigorously followed, and IBC approval conditions for the conduct of research are being followed."
P-074	Section III-B - Responsibilities of the Institutional Biosafety Committee (IBC)	The draft's effort to identify specific categories for immediate notification and follow-up reporting is supported. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.	Retain the specific categories and examples for immediate notification and follow-up reporting.
P-075	Section IV - Categories of Oversight for Research Based on Risk	The subsection identification scheme for this section is inconsistent, using numbers instead of letters.	Use IV-A, IV-B, etc.

Draft incident reporting template (1)

ID	Section / item	Comment	Suggested change
I-006 Proposed priority†	Part 4. Root Cause Analysis and Corrective Actions	Separate Root Cause analysis and Corrective Actions	Part 4 and Part 5 (include plan to prevent re-occurrence)

Draft IBC meeting minutes template (3)

ID	Section / item	Comment	Suggested change
M-002 Proposed priority†	General Meeting Information	New Business, Incidents, Inspections, IBC Trainings - needs a break from the information noted above that is required for each new submission for review	Correct formatting
M-003 Proposed priority†	New IBC Registrations and Amendments for Review	Clarify "Readout of Any Projects Approved by Delegated Review Document all approvals granted by delegated review (may be attached to the minutes as a list).	—
M-004 Proposed priority†	Other Comments	The template doesn't have headers distinguishing the different sections, so the review blends into other business.	If the formatting must be followed exactly, include clearer section breaks.

264. Fred Hutch Cancer Center

I am responding: On behalf of an organization

Name: Susan Parazzoli

Name of Organization: Fred Hutch Cancer Center

Type of Organization: Non-Profit Research Organization

Role: Other

Role - Other: Biosafety Officer

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer and infectious disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Under Section II, Scope, list number 2. Cells, viruses, or organisms, other than plants, that have been genetically modified; does this include past modifications not made by the PI?
In other words, does "genetically modified" include cells, viruses, or organisms that were modified previously by another investigator, institution, manufacturer, or commercial supplier? If so, please clarify whether all subsequent research involving such materials remains subject to the Policy regardless of the age, provenance, or nature of the original modification. Please also clarify what information investigators are expected to obtain regarding historical modifications when complete provenance is unavailable.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Advocate for continued use of Risk Groups as the baseline for risk assessment, especially for those that are being genetically modified.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: See attached for multiple comments.

6. Other feedback relevant to this resource: See attached.

Uploaded File: Fred-Hutch-Comments-to-NIH-Biosafety-Policy-10.19.26.docx

Policy Scope

1. Under Section II, Scope, list number 2. *Cells, viruses, or organisms, other than plants, that have been genetically modified*; does this include past modifications not made by the PI?

In other words, does "genetically modified" include cells, viruses, or organisms that were modified previously by another investigator, institution, manufacturer, or commercial supplier? If so, please clarify whether all subsequent research involving such materials remains subject to the Policy regardless of the age, provenance, or nature of the original modification. Please also clarify what information investigators are expected to obtain regarding historical modifications when complete provenance is unavailable.

Review pathways and low-risk research

2. Will NIH retain an exemption/no-IBC-review pathway for **low-risk activities** such as certain plasmids, PCR products, transgenic rodents, and genetically modified cells?

3. Please **define** "low-risk transgene," "well-characterized cell line," "minor amendment," and "transgenic organism" and please provide examples for delegated versus full-committee review.

4. Are **naked DNA/RNA**, non-expressing PCR products, oligonucleotides, and extracted nucleic acids outside cells, organisms, or viruses subject to the Policy? If so, under what category?

Clinical Research:

5. Please **confirm that clinical activities** conducted solely for diagnosis, treatment, or routine patient care—including standard blood draws, specimen transport, diagnostic testing, and disposal—are outside the Policy because they are not biomedical research. For collections serving both clinical care and research, please specify when IBC jurisdiction begins: at collection, upon separation or designation of the research aliquot, or when research-specific processing begins.

6. **Routine human specimens**: Does NIH intend all biomedical research handling unfixed human blood, tissues, bone marrow, primary cells, or other native human specimens to receive IBC review because such materials may contain adventitious agents, or only work presenting a defined risk above ordinary Bloodborne Pathogens/Universal Precautions controls?

7. **Adventitious-agent threshold**: When is a primary cell considered contaminated by an adventitious agent? Is the phrase a universal assumption for all primary cells, or does it require a known, suspected agent?

8. **CAR T-cell replication**: In the phrase "products that are capable of shedding, replicating, or integrating," does "replicating" mean autonomous replication of a biological agent/vector, or does it include normal mitotic proliferation of cellular products such as CAR T cells?

Incidents and noncompliance reporting

9. Please define “compliance violation,” “significant problem,” “incident,” “potential exposure,” “loss of containment,” “release,” “facility failure,” “equipment failure,” and “potential laboratory-acquired infection.” NIH should establish objective thresholds that distinguish events requiring internal institutional correction, events requiring IBC review, and events requiring NIH notification

10. Would the following be NIH-reportable absent an exposure or release: failure to wear a lab coat or use of incorrect PPE; late annual training; an expired BSC certification; incomplete signage; work by a person omitted from a protocol roster; or a minor deviation from an approved SOP?

11. Are all lower-risk incidents reviewed by the IBC required to generate individual public incident reports, including animal bites, scratches, escapes, first-aid-only events, and low-risk exposures?

12. May institutions report low-risk, non-NIH-reportable events in aggregate on an annual or semiannual basis to preserve transparency while avoiding a disproportionate administrative burden?

13. **Suggestion: NIH should not require Principal Investigator’s name to appear on publicly posted incident reports. This is not necessary to communicate the nature of the incident, root causes, institutional response or corrective actions. Naming the PI would only discourage reporting and undermine the function of our biosafety program because we rely on these reports to investigate individual events, identify trends, recommend mitigation measures and develop training that prevents future injuries, exposures, and releases. It also places an undue personal responsibility on the PI when the incident may involve institutional systems, facilities or equipment. NIH could collect PI names confidentially when needed, and only require posting of lessons learned, corrective actions, and prevention of recurrence. We would also like to remind the NIH at their own engagement process- feedback was given that anonymous reporting encouraged reporting**.

Meeting minutes and public posting

14. Please confirm that minutes may be approved at the next **regularly scheduled** convened meeting and posted immediately afterward; no interim or specially convened meeting is required solely to approve minutes. If meeting dates are prolonged, then specify a timeframe for posting the minutes. Most IBCs meet monthly or bi-monthly. NIH should clarify that institutions are not required to convene a special meeting solely to approve minutes

15. Is the draft template mandatory in layout and field order, or may institutions **use their own format** if it captures NIH-defined minimum content? Current NIH guidance specifically states that use of the specific template is not required.

16. Can **routine low-risk protocols and delegated approvals be presented in tables, appendices, or batched summaries** rather than full narrative entries for every protocol in the IBC minutes? Can the NIH adopt some sort of risk-appropriate documentation standard so that lower-risk work would require a less complex description? Current NIH minutes allow for variability in complexity and risk with documentation proportional to those levels

Implementation Period

17. Please allow at least 12 months for full implementation after final guidance and templates are provided so that institutions can keep up with the current workload and have time to identify newly covered work.

18. Request that the NIH submit another draft policy for review before finalizing. The current NIH Guidelines have been in existence for 50 years and rushing into a new Policy will leave unintended gaps and possible oversights with potentially serious consequences.

    If NIH makes substantial changes to scope, review requirements, incident-reporting thresholds, public-disclosure requirements, or institutional assurance requirements in response to these comments, NIH should provide an additional opportunity for stakeholder review before those provisions become effective.

Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards

Response to NOT-OD-26-112

October 12, 2026

Submitted Electronically

The Campus Safety, Health, and Environmental Management Association (CSHEMA) is the premier association for environmental health and safety leadership in higher education. CSHEMA represents institutions that range from large research-intensive universities with mature biosafety programs to smaller colleges that may have limited or no dedicated biosafety staff. Our members include biosafety professionals, environmental health and safety practitioners, and institutional leaders responsible for implementing biosafety requirements across diverse research and teaching environments.

CSHEMA appreciates NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions. **Due to such uncertainty in the final requirements, CSHEMA encourages NIH to provide an opportunity for public review and comment on the next draft before it is finalized.**

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." The policy should clarify whether precautionary post exposure prophylactic treatment is considered "agent-specific treatment". It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

6. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

CSHEMA recommends that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

Conclusion

CSHEMA supports NIH's goal of modernizing biosafety oversight and appreciates the draft's movement toward broader risk awareness, clearer incident thresholds, delegated review, and national safety learning. For the policy to succeed, however, modernization must strengthen the institutional systems that perform biosafety work rather than simply expand their obligations.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified

local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

CSHEMA respectfully requests that NIH revise the draft consistent with these recommendations, release complete implementation materials for public review, pilot key templates and processes, and provide a minimum 24-month phased implementation period. CSHEMA welcomes continued engagement and would be pleased to assist NIH in testing implementation resources or gathering additional institutional perspectives.

Sincerely,

Robin Izzo
President
Campus Safety, Health, and Environmental Management Association

266. University of Wisconsin-Milwaukee

I am responding: On behalf of an organization

Name: Jill McClary-Gutierrez

Name of Organization: University of Wisconsin-Milwaukee

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Expansion of scope beyond recombinant techniques is logical and appropriate
The scope of the new policy ("all biomedical research, in laboratory settings, involving biohazards") is an appropriate change from the previous NIH Guidelines. The new scope limits oversight to NIH's funding priorities by excluding plants, while increasing oversight to include wild-type pathogens. These changes are logical and aligned with the purpose of the Policy.

Definition of "biohazards" requires significant clarification and examples
The Policy defines research involving biohazards as "research involving known or potential risk to human health and any of the following:
1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above."
NIH should provide examples to clarify the phrase "known or potential risk to human health." This phrasing as provided is far too broad and open to interpretation. What level of risk would be considered significant, or is any risk, no matter how small, subject to the Policy's oversight? For example, wild-type Risk Group 1 agents are excluded from the Policy, presumably because of a lack of risk to human health; but it is unclear if a genetically modified Risk Group 1 agent expressing only a reporter transgene would be considered a biohazard under the Policy and who is meant to make that determination. The existing NIH Guidelines contain specific Exemptions where the agents in use do not present a significant risk to health or the environment (e.g., E. coli K-12, S. cerevisiae, certain activities involving transgenic rodents, etc). It is unclear if these organisms would be Exempt when genetically modified under the new Policy. Similarly, it is unclear if all primary cells and cell lines (including, for example, murine or insect cells) are included within the Policy scope, or only those that harbor human infectious agents.

Definition of "toxin" requires refinement
The Policy defines Toxin as "A protein or peptide produced by living organisms that causes harm in

humans." This definition is far too vague. First, not all biological toxins are proteins or peptides (e.g., T-2 toxin); are such toxins excluded from the policy's oversight? Second, describing a toxin as any protein that "causes harm in humans" includes other protein classes that are not toxins (e.g., oncogenic proteins, allergens). NIH should refine this definition and should include reference to a practical LD50, as the scientific standard for classifying toxicity.

Definitions of "emerging agent or organism" and "zoonotic" require clarification
The definitions of "emerging agent or organism" and "zoonotic" require significant clarification and examples to ensure they are reasonably applied, especially given the Policy's requirement for NIH review and input for any research involving an emerging or zoonotic agent without a current RG or containment level classification. As written, the definitions for these agent categories are extremely broad and would be difficult to apply in practice. For example, would studies that involve screening environmental samples for previously unidentified organisms or strains require NIH review for each strain identified? At what point in such research would NIH review be required: at the initiation of the work because there is a chance of identifying a new agent, or only after the agent has been fully characterized and deemed both novel and potentially pathogenic? What constitutes a "newly identified" agent? Must it be a species that has not been published in literature? What about new strains of previously known species? What qualifies as "reasonable suspicion" of transmission from animals to humans? Such questions about practical application of the definitions limit their utility and may lead to overwhelming need for NIH input on relatively low risk (BSL-2) studies. We suggest that NIH limit the definitions to organisms with potential for serious or lethal human disease, as assessed by the PI in consultation with the IBC. We also request clarification regarding expected oversight for studies involving screening or culture of unknown organisms from clinical or environmental samples.

Clarify "biomedical research" definition and supply a definition of "research"
The Policy's definition of "biomedical research" under its scope is written as "research on a topic that is within the mission of the NIH, including applicability to: research supported by NIH, and non-NIH funded research that is conducted at an institution that receives any NIH funding." NIH should update the definition to address the following gaps.
First, NIH should clarify what is meant by "non-NIH funded research". As written, it is unclear if this refers to any research that is not funded by the NIH, or any funded research that is not funded by the NIH.
Second, NIH should take this new Policy implementation as an opportunity to clarify a definition of "research." Biohazards are used in many different non-research projects, such as teaching, clinical testing, or manufacturing. While safety is necessary for all biohazard handling, the oversight structures of this Policy are specific to research and should be clarified as such with a definition of research. As a model, human subjects research requiring Institutional Review Board (IRB) review has clear and established definitions of both "human subjects" and of "research".

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Creation of delegated review category is a positive change
The new Policy creates a pathway for "delegated" review by an individual or subgroup of IBC members which does not exist in the current NIH Guidelines. This review pathway is a positive change, allowing for faster turnaround for low-risk studies and creating processes that are akin to other compliance committees (e.g., IRB, IACUC).

Refining definitions is necessary to ensure oversight is calibrated to risk
As stated previously, NIH must refine and provide examples for terms including “biohazards”, “emerging agents”, and “zoonotic” to ensure it is clear what level of human health risk is truly relevant to the new Policy. This clarification should help to ensure that the tiered oversight structure in the new Policy is properly calibrated to risk. Additional terminology that is unclear or appears to require excessive review is listed below. NIH should provide examples of what falls within these terms and what does not for consistent application of the Policy:
- “Primary cells that may be contaminated with adventitious agents”: By definition, primary cells are less well-characterized than other cell lines. Primary cells collected from laboratory rodents that have not been treated with infectious agents should not require full IBC review.
- “Transgenic organisms”: Clarify the difference between “genetically modified” and “transgenic” for oversight purposes.
- “Reporter or low-risk transgenes”: Provide examples for consistent implementation.
- “Well-characterized cell lines”: What qualifies as “well-characterized”?

3. Continued utility of Risk Groups: Risk Group lists must be frequently updated and publicly shared by NIH
Reliance on Risk Groups as a baseline for risk assessment is acceptable, as this practice is already widespread and allows a base level of consistency between institutions. However, because the Policy continues to depend on Risk Groups and requires NIH input for Risk Group determination, the NIH must publicly share and frequently update Risk Group lists based on requests for input from institutions. This practice of sharing all Risk Group determinations publicly at the federal level will promote consistency across institutions, while reducing administrative burden at both institutional and federal levels for review of identical agents from multiple institutions.

Clarify the role of the BMBL as an advisory document
The existing NIH Guidelines contain requirements for various biosafety levels, which the new Policy removes in favor of aligning biosafety levels with those described in Biosafety in Microbiological and Biomedical Laboratories (BMBL). We support this change as it helps to reduce redundancy and/or conflict between biosafety level definitions applied by different agencies. However, we believe the new Policy should clarify its expectation in use of the BMBL as an advisory document. The BMBL was not written as a policy requirement. While it provides an excellent framework for best practice, institutions should be able to adapt and deviate from the BMBL when justified and appropriate for their specific circumstances.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public posting of individual incident reports will create privacy issues, increase administrative burden, and reduce reporting rates.
We have significant concern regarding the requirement for public posting of individual incident reports, especially given the level of detail included in the required Incident Reporting template and the minimal immediate value in public reporting on low-risk incidents. While we agree with the aim of transparency and the value of consistency in reported data across institutions, we do not see these values truly enhanced by public reporting of individual incidents on institutional websites for the following reasons:

- The Policy includes development of a National Biosafety Data and Safety Analysis Center where all NIH-reportable and voluntarily submitted incident reports would be aggregated, de-identified, and analyzed. This Center provides true value in advancing the metascience of biosafety by centralizing incident data. Institutionally posted incident reports do not add to that goal.
- Short summaries of incidents are already included for required public posting in IBC Meeting Minutes according to the required template. If the goal of posting individual incident reports is to ensure public awareness, posting of IBC Meeting Minutes already meets this need, making posting of individual Incident Reports redundant.
- Regardless of the ability to redact names from incident reports, we are concerned that posting of individual incident reports will violate privacy of those involved. At smaller institutions or in smaller research labs, listing an individual's job title effectively identifies that individual. We have significant concern about the implications of this for protecting individual health information.
- Instead of providing value, we strongly suspect that researchers may view incident report posting as punitive and that this requirement will significantly decrease the number of incident reports notified to biosafety programs, thus directly reducing biosafety programs' ability to promote the safety that the Policy aims to support.

We instead suggest an alternative approach to strike a balance between immediate transparency, institutional administrative burden, and advancement of biosafety:

- If the goal of incident report posting is to improve biosafety and increase public transparency, we believe the required reporting structure for NIH-reportable incidents and collection of data in the National Biosafety Data and Safety Analysis Center, without institutional posting of individual reports, meets this need for NIH-reportable incidents.
- Non-NIH-reportable incidents are lower risk, thus making immediate posting for public transparency of limited value and a potentially high administrative burden. We propose that institutions instead be required to post or provide to NIH an annual summary of these lower risk incidents at their institutions. This would be similar to annual reporting of OSHA recordable incidents. This process would remove the privacy concerns around posting individual reports, while maintaining a focus on transparency and accountability to the public and encouraging institutions to periodically evaluate their incident data for trends, thus promoting continuous improvement.

24-hour notification for compliance violations is not reasonable or valuable

The new Policy codifies immediate (i.e., within 24 hours) notification for certain types of incidents, which has been the expected practice under the existing NIH Guidelines for high-risk incidents. However, the new Policy stipulates required immediate notification for all NIH-reportable incidents, including "any compliance violations at any BSL/ABSL". Compliance violations that do not also involve a serious incident should require the standard 30-day reporting only. This reduces the administrative burden on reporting these cases when there is no immediate risk resulting from the violation, while maintaining a standard of reporting all compliance violations to the NIH.

Incident Reporting Template should not require funding information

The Incident Reporting Template includes fields for NIH grant number, NIH funding institute, and NIH program officer. We do not see the value in including this information in incident reports and suspect it will be perceived as punitive, leading to fewer incident reports and undermining the safety culture that the Policy aims to support.

IBC Meeting Minutes Template should be recommended, not required
Requiring a specific IBC Meeting Minutes template creates an administrative burden and compliance challenge that does not directly support safety or transparency. While we can see value in a shared format across institutions, this value does not outweigh the administrative burden of updating existing, functional systems to match a specific template. We suggest instead that the Meeting Minutes Template be provided as a recommended resource, as was done in 2025 when the requirement for public posting of meeting minutes went into effect. To support the recommended template, there should also be a clear list of the minimum required information to help institutions meet compliance requirements. No other similar compliance committee (e.g., IRB, IACUC) has a required meeting minutes template at the federal level.

6. Other feedback relevant to this resource: Implementation timeline is too short
The 6-month implementation timeline is far too short. The Policy significantly expands scope from the prior NIH Guidelines, and effective implementation will require institution-wide policy changes, development of new procedures and forms to match required templates, and re-education of campus stakeholders. As a public academic institution, many of our campus processes are influenced by fiscal or academic year calendars, making a timeline of less than one year impractical. We request at least one year, as has been typical for other new federal biosafety policies in recent years.

Supporting materials should be provided for Biosafety Assurance documentation
NIH should supply an example of the Biosafety Assurance documentation to aid institutions in meeting this new requirement. This resource would be akin to the Assurance Sample Document provided by OLAW for verifying compliance with the Policy on Humane Care and Use of Laboratory Animals.

RE: Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

October 15, 2026

The University of Wisconsin-Milwaukee thanks the NIH for providing an opportunity to comment on the draft NIH Biosafety Policy for Research Involving Biohazards. We are writing on behalf of the University to provide our feedback.

Overall, we agree with the risk-based and technology-agnostic approach to biosafety taken by the draft NIH Policy. This approach is a welcome change from the existing NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules.

However, we have significant concerns about implementation of the draft NIH Policy as written. These concerns focus primarily on unclear scope, vague definitions, and increased administrative burden for our Biosafety Program and PIs. Specific comments are provided below based on the NIH's requested feedback categories.

Comments regarding appropriateness of scope and definitions

Expansion of scope beyond recombinant techniques is logical and appropriate

The scope of the new policy ("all biomedical research, in laboratory settings, involving biohazards") is an appropriate change from the previous NIH Guidelines. The new scope limits oversight to NIH's funding priorities by excluding plants, while increasing oversight to include wild-type pathogens. These changes are logical and aligned with the purpose of the Policy.

Definition of "biohazards" requires significant clarification and examples

The Policy defines research involving biohazards as "research involving known or potential risk to human health and any of the following:

1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above."

NIH should provide examples to clarify the phrase "known or potential risk to human health." This phrasing as provided is far too broad and open to interpretation. What level of risk would be considered significant, or is any risk, no matter how small, subject to the Policy's oversight? For example, wild-type Risk Group 1 agents are excluded from the Policy, presumably because of a lack of risk to human health; but it is unclear if a genetically modified Risk Group 1 agent expressing only a reporter transgene would be considered a biohazard under the Policy and who is meant to make that determination. The existing NIH Guidelines contain specific Exemptions where the agents in use do not present a significant risk to health or the environment (e.g., *E. coli* K-12, *S. cerevisiae*, certain activities involving transgenic rodents, etc). It is unclear if these organisms would be Exempt when genetically modified under the new Policy. Similarly, it is unclear if all primary cells and cell lines (including, for example, murine or insect cells) are included within the Policy scope, or only those that harbor human infectious agents.

Definition of "toxin" requires refinement

The Policy defines Toxin as "A protein or peptide produced by living organisms that causes harm in humans." This definition is far too vague. First, not all biological toxins are proteins or peptides (e.g., T-2 toxin); are such toxins excluded from the policy's oversight? Second, describing a toxin as any protein that "causes harm in humans" includes other protein classes that are not toxins (e.g., oncogenic proteins, allergens). NIH should refine this definition and should include reference to a practical LD50, as the scientific standard for classifying toxicity.

Definitions of "emerging agent or organism" and "zoonotic" require clarification

The definitions of "emerging agent or organism" and "zoonotic" require significant clarification and examples to ensure they are reasonably applied, especially given the Policy's requirement for NIH review and input for any research involving an emerging or zoonotic agent without a current RG or containment level classification. As written, the definitions for these agent categories are extremely broad and would be difficult to apply in practice. For example, would studies that involve screening environmental samples for previously unidentified organisms or strains require NIH review for each strain identified? At what point in such research would NIH review be required: at the initiation of the work because there is a chance of identifying a new agent, or only after the agent has been fully characterized and deemed both novel and potentially pathogenic? What constitutes a "newly identified" agent? Must it be a species that has not been published in literature? What about new strains of previously known species? What qualifies as "reasonable suspicion" of transmission from animals to humans? Such questions about practical application of the definitions limit their utility and may lead to overwhelming need for NIH input on relatively low risk (BSL-2) studies. We suggest that NIH limit the definitions to organisms with potential for serious or lethal human disease, as assessed by the PI in consultation with the IBC. We also request clarification regarding expected oversight for studies involving screening or culture of unknown organisms from clinical or environmental samples.

Clarify "biomedical research" definition and supply a definition of "research"

The Policy's definition of "biomedical research" under its scope is written as "research on a topic that is within the mission of the NIH, including applicability to: research supported by NIH, and non-NIH funded research that is conducted at an institution that receives any NIH funding." NIH should update the definition to address the following gaps.

First, NIH should clarify what is meant by "non-NIH funded research". As written, it is unclear if this refers to any research that is not funded by the NIH, or any *funded* research that is not funded by the NIH. Second, NIH should take this new Policy implementation as an opportunity to clarify a definition of "research." Biohazards are used in many different non-research projects, such as teaching, clinical testing, or manufacturing. While safety is necessary for all biohazard handling, the oversight structures of this Policy are specific to research and should be clarified as such with a definition of research. As a model, human subjects research requiring Institutional Review Board (IRB) review has clear and established definitions of both "human subjects" and of "research".

Comments regarding appropriateness of tiered oversight and calibration to risk

Creation of delegated review category is a positive change

The new Policy creates a pathway for "delegated" review by an individual or subgroup of IBC members which does not exist in the current NIH Guidelines. This review pathway is a positive change, allowing for faster turnaround for low-risk studies and creating processes that are akin to other compliance committees (e.g., IRB, IACUC).

Refining definitions is necessary to ensure oversight is calibrated to risk

As stated previously, NIH must refine and provide examples for terms including "biohazards", "emerging agents", and "zoonotic" to ensure it is clear what level of human health risk is truly relevant to the new Policy. This clarification should help to ensure that the tiered oversight structure in the new Policy is properly calibrated to risk. Additional terminology that is unclear or appears to require excessive review is listed below. NIH should provide examples of what falls within these terms *and* what does not for consistent application of the Policy:

- "Primary cells that may be contaminated with adventitious agents": By definition, primary cells are less well-characterized than other cell lines. Primary cells collected from laboratory rodents that have not been treated with infectious agents should not require full IBC review.
- "Transgenic organisms": Clarify the difference between "genetically modified" and "transgenic" for oversight purposes.
- "Reporter or low-risk transgenes": Provide examples for consistent implementation.
- "Well-characterized cell lines": What qualifies as "well-characterized"?

Comments regarding continued utility of Risk Groups (RGs) as a baseline for risk assessment versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

Risk Group lists must be frequently updated and publicly shared by NIH

Reliance on Risk Groups as a baseline for risk assessment is acceptable, as this practice is already widespread and allows a base level of consistency between institutions. However, because the Policy continues to depend on Risk Groups and requires NIH input for Risk Group determination, the NIH must publicly share and frequently update Risk Group lists based on requests for input from institutions. This practice of sharing all Risk Group determinations publicly at the federal level will promote consistency across institutions, while reducing administrative burden at both institutional and federal levels for review of identical agents from multiple institutions.

Clarify the role of the BMBL as an advisory document

The existing NIH Guidelines contain requirements for various biosafety levels, which the new Policy removes in favor of aligning biosafety levels with those described in Biosafety in Microbiological and Biomedical Laboratories (BMBL). We support this change as it helps to reduce redundancy and/or conflict between biosafety level definitions applied by different agencies. However, we believe the new Policy should clarify its expectation in use of the BMBL as an advisory document. The BMBL was not written as a policy requirement. While it provides an excellent framework for best practice, institutions should be able to adapt and deviate from the BMBL when justified and appropriate for their specific circumstances.

Comments regarding mechanisms to encourage and accommodate voluntary compliance

No comments

Comments on incident reporting and meeting minutes, including templates

Public posting of individual incident reports will create privacy issues, increase administrative burden, and reduce reporting rates.

We have significant concern regarding the requirement for public posting of individual incident reports, especially given the level of detail included in the required Incident Reporting template and the minimal immediate value in public reporting on low-risk incidents. While we agree with the aim of transparency and the value of consistency in reported data across institutions, we do not see these values truly enhanced by public reporting of individual incidents on institutional websites for the following reasons:

- The Policy includes development of a National Biosafety Data and Safety Analysis Center where all NIH-reportable and voluntarily submitted incident reports would be aggregated, de-identified, and analyzed. This Center provides true value in advancing the metascience of biosafety by centralizing incident data. Institutionally posted incident reports do not add to that goal.
- Short summaries of incidents are already included for required public posting in IBC Meeting Minutes according to the required template. If the goal of posting individual incident reports is to ensure public awareness, posting of IBC Meeting Minutes already meets this need, making posting of individual Incident Reports redundant.
- Regardless of the ability to redact names from incident reports, we are concerned that posting of individual incident reports will violate privacy of those involved. At smaller institutions or in smaller research labs, listing an individual's job title effectively identifies that individual. We have significant concern about the implications of this for protecting individual health information.
- Instead of providing value, we strongly suspect that researchers may view incident report posting as punitive and that this requirement will significantly decrease the number of incident reports notified to biosafety programs, thus directly reducing biosafety programs' ability to promote the safety that the Policy aims to support.

We instead suggest an alternative approach to strike a balance between immediate transparency, institutional administrative burden, and advancement of biosafety:

- If the goal of incident report posting is to improve biosafety and increase public transparency, we believe the required reporting structure for NIH-reportable incidents and collection of data in the

National Biosafety Data and Safety Analysis Center, without institutional posting of individual reports, meets this need for NIH-reportable incidents.

- Non-NIH-reportable incidents are lower risk, thus making immediate posting for public transparency of limited value and a potentially high administrative burden. We propose that institutions instead be required to post or provide to NIH an annual summary of these lower risk incidents at their institutions. This would be similar to annual reporting of OSHA recordable incidents. This process would remove the privacy concerns around posting individual reports, while maintaining a focus on transparency and accountability to the public and encouraging institutions to periodically evaluate their incident data for trends, thus promoting continuous improvement.

24-hour notification for compliance violations is not reasonable or valuable

The new Policy codifies immediate (i.e., within 24 hours) notification for certain types of incidents, which has been the expected practice under the existing NIH Guidelines for high-risk incidents. However, the new Policy stipulates required immediate notification for *all* NIH-reportable incidents, including "any compliance violations at any BSL/ABSL". Compliance violations that do not also involve a serious incident should require the standard 30-day reporting only. This reduces the administrative burden on reporting these cases when there is no immediate risk resulting from the violation, while maintaining a standard of reporting all compliance violations to the NIH.

Incident Reporting Template should not require funding information

The Incident Reporting Template includes fields for NIH grant number, NIH funding institute, and NIH program officer. We do not see the value in including this information in incident reports and suspect it will be perceived as punitive, leading to fewer incident reports and undermining the safety culture that the Policy aims to support.

IBC Meeting Minutes Template should be recommended, not required

Requiring a specific IBC Meeting Minutes template creates an administrative burden and compliance challenge that does not directly support safety or transparency. While we can see value in a shared format across institutions, this value does not outweigh the administrative burden of updating existing, functional systems to match a specific template. We suggest instead that the Meeting Minutes Template be provided as a recommended resource, as was done in 2025 when the requirement for public posting of meeting minutes went into effect. To support the recommended template, there should also be a clear list of the minimum required information to help institutions meet compliance requirements. No other similar compliance committee (e.g., IRB, IACUC) has a required meeting minutes template at the federal level.

Comments on implementation, resources, and guidance

Implementation timeline is too short

The 6-month implementation timeline is far too short. The Policy significantly expands scope from the prior NIH Guidelines, and effective implementation will require institution-wide policy changes, development of new procedures and forms to match required templates, and re-education of campus stakeholders. As a public academic institution, many of our campus processes are influenced by fiscal or

academic year calendars, making a timeline of less than one year impractical. We request at least one year, as has been typical for other new federal biosafety policies in recent years.

Supporting materials should be provided for Biosafety Assurance documentation

NIH should supply an example of the Biosafety Assurance documentation to aid institutions in meeting this new requirement. This resource would be akin to the Assurance Sample Document provided by OLAW for verifying compliance with the Policy on Humane Care and Use of Laboratory Animals.

Other Comments

NIH should be held to a specific timeline for reviewing containment lowering requests and determining containment levels

The Policy indicates that NIH is responsible for "determining the appropriate containment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available" and "reviewing requests for lowering containment levels in a timely manner." These activities, which have direct impact on the ability of researchers to begin work, should be held to a reasonable and specific timeline. The policy assigns specific timeline requirements for IBCs related to incident reporting (24 hours or 30 days); NIH should hold themselves to a similar standard as a demonstration of shared responsibility and commitment to enabling safe and secure biomedical research. "A timely manner" is not specific enough.

UW-Milwaukee is committed to protecting the health and safety of our personnel and community. We ask NIH to make changes to and provide clarifications for the draft Policy as described above. We believe these changes and clarifications will allow for the Policy's effective implementation in a manner that promotes safety, allows flexibility, and reduces unnecessary administrative burden.

Sincerely,

IBC Chair

267. Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center

I am responding: On behalf of an organization

Name: Elizabeth Burrola

Name of Organization: Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center

Type of Organization: Non-Profit Research Organization

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: see attached document

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): see attached document

3. Continued utility of Risk Groups: see attached document

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): see attached document

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: see attached document

6. Other feedback relevant to this resource: see attached document

Uploaded File: Recommendations-to-OSP-RE-Draft-Policy-10-16-2026.docx

We support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate

director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety

program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and

near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request.

Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

268. COGR, AAU, & APLU

I am responding: On behalf of an organization

Name: Kristin West

Name of Organization: COGR, AAU, & APLU

Type of Organization: Other

Type of Organization - Other: Non-profit associations of academic research institutions

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Not applicable

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Please see attached comment letter.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Please see attached comment letter.

3. Continued utility of Risk Groups: Please see attached comment letter.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Please see attached comment letter.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Please see attached comment letter.

6. Other feedback relevant to this resource: Please see attached comment letter.

RE: Response to Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards

To Whom It May Concern:

The Association of American Universities (AAU), Association of Public and Land-grant Universities (APLU), and COGR write to offer comments in response to the Draft NIH Biosafety Policy for Research Involving Biohazards (Draft Policy) published in the Federal Register on September 14, 2026. [91 FR 58132].

Founded in 1900, AAU comprises 69 of America's leading research universities that transform lives through education, research, and innovation. Research universities, including AAU members, have a long-standing partnership with the federal government to advance science and technology in the national interest. This partnership, rooted in World War II, has been central to U.S. global leadership in science and technology.

APLU is a membership organization that advances the mission of land-grant and public research universities. Founded in 1887, APLU is the oldest higher education association in the United States. Its U.S. membership consists of more than 240 land-grant and public research universities, state university systems, and affiliated organizations spanning across all 50 states, the District of Columbia, and five U.S. territories. The association and its members

collectively focus on increasing student success and workforce readiness; promoting pathbreaking scientific research; and bolstering economic and community engagement. Annually, its U.S. member campuses enroll 4.6 million undergraduates and 1.4 million graduate students, award 1.3 million degrees, employ 1.3 million faculty and staff, and conduct $70 billion in university-based research.

COGR is the national authority on federal policies and regulations affecting U.S. research institutions. We provide a unified voice for over 230 research universities and affiliated academic medical centers and research institutes. Our work strengthens the research partnership between the federal government and research institutions and furthers the frontiers of science, technology, and knowledge. We advocate for effective and efficient research policies and regulations that maximize and safeguard research investments and minimize administrative and cost burdens.

The academic research institutions that AAU, APLU, and COGR represent understand and support NIH's desire to update its current Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules ("NIH Guidelines") beyond the changes that were incorporated into those Guidelines in April 2024. Our member institutions are leaders in the conduct of biomedical research and fully support risk-based policies that protect researchers and the public from biohazards, while facilitating conduct of the broad spectrum of life sciences research necessary to ensure America's ability to understand and address threats to individual and public health. They also support regulations that embue biosafety officers (BSOs) and institutional biosafety committees (IBCs) with the power and authority to provide oversight for research involving biohazards.

Unfortunately, the Draft Policy does not callibrate required controls to actual risk presented, particularly in the case of lower-risk research activities. During the stakeholder consultation process, we were encouraged by discussions regarding how the Draft Policy could take a more risk-based approach to regulation. However, the Draft Policy does not retain many of the risk-based features of the NIH Guidelines. Instead, it adopts an overly risk-averse approach that substantially increases institutions' review and oversight responsibilities for low-risk research that was previously exempt.

The Draft Policy also places significant responsibilities on biosafety officers (BSOs), Institutional Biosafety Committees (IBCs), and institutions, but it fails

to empower them to carry out these responsiblities with sufficient independence and authority, along the lines that institutional review boards (IRBs) and institutional animal care and use committees (IACUCs) do under their governing regulations. Instead, the Draft Policy's vast scope (which includes virtually ALL research involving biological agents conducted at any institution that receives NIH funding), coupled with its overly prescriptive and risk averse requirements for IBC review, oversight and reporting functions, will substantially increase administrative burden while diverting limited biosafety resources from higher-risk activities, potentially undermining, rather than increasing, laboratory and public safety. Further, despite requiring institutions to provide review and oversight for non-NIH/non-federally funded research, the Draft Policy provides neither statutory support for these requirements nor mechanisms to reimburse institutions for associated implementation costs. Accordingly, as an overarching comment, we urge NIH to reevaluate both the scope of the Draft Policy and its risk calibration.

Below, are additional general comments regarding the Draft Policy, followed by comments and recommendations on specific policy provisions. In addition, our organizations recommend NIH consider using a notice of proposed rulemaking that includes the statutory basis for the proposed changes and a regulatory-impact analysis to facilitate such an extensive policy change.

GENERAL COMMENTS

▪**Intersection between Draft Policy and United States Government Policy for Stopping High Risk Life Sciences Research ("USG Policy"):** Given the Draft Policy's coverage of "research involving biohazards" and the USG Policy's coverage of broadly defined "Potential Dangerous Gain of Function (DGOF) Research" and "Other Risky International Research," there is substantial potential for overlap between the two policies. Unfortunately, the USG Policy had not been issued at the time that NIH was collecting stakeholder input on the Draft Policy. Further, NIH has not yet issued its implementation guidance for the USG Policy. Thus, institutions do not have any information on how NIH anticipates the Draft Policy will intersect with the USG Policy. Accordingly, it seems premature to collect stakeholder input on the Draft Policy, until NIH is in a position to provide these details.
Recommendation: Our associations urge NIH to extend the final date of the comment period on the Draft Policy to a date that falls at least 60 days after NIH has released its implementation guidance for the USG Policy and provides information on how the two policies intersect.

▪**Scope of Draft Policy Exceeds Statutory Authority:** NIH cites no statutory authority to support extending the scope of the Draft Policy to "non-funded NIH research that is conducted . . . at an institution that receives any NIH funding" ("Funded Institution"). Indeed, the only reference to biological agents and toxins contained in the statute prescribing the NIH director's duties/authorities is a requirement for the director to consult with named federal agencies/offices, "as appropriate, ***regarding research needs*** to advance medical countermeasures to diagnose, mitigate, prevent, or treat harm from any biological agent or toxin, including emerging infectious diseases, chemical, radiological, or nuclear agents that may cause a public health emergency or other research needs related to emerging public health threats." [42 USC §282(b)(26) (***emphasis added***)].
Recommendation: NIH should provide the explicit statutory authority that authorizes it to include within the Draft Policy's scope non-federally funded research conducted at a Funded Institution, or, in the absence of such explicit authority, confine the Draft Policy's scope to NIH-funded research. Further, as noted, given the scope and magnitude of the Draft Policy, NIH should consider issuing the Draft Policy through the federal notice and comment rulemaking process, as opposed to issuing it as an agency policy.

▪**Draft Policy is Not Accurately Risk Calibrated and Places Substantial and Unjustified Administrative and Cost Burdens on Institutions:** Although the Draft Policy claims to support a risk-based approach to the review and oversight of biomedical research, its approach is not accurately risk calibrated. Specifically, the Draft Policy is overly risk-averse because it vastly increases the scope of research requiring IBC and/or NIH review by eliminating categories of low-risk research that were previously exempt from IBC review processes. Further, the Draft Policy's provisions concerning inspections, continuing reviews, and other oversight activities also lack risk calibration and/or are duplicative of oversight efforts in place via other regulatory and institutional mechanisms (e.g., IACUC semi-annual inspections, institutional lab safety inspections).

NIH's failure to "right-size" the draft Policy to the level of risk presented by specific activities results in unnecessary oversight for lower-risk activities, which in turn diverts resources that could be more effectively devoted to managing higher risk research. Further, NIH expects Funded Institutions to perform these responsibilites for ALL non-NIH funded research within the policy's scope. Yet, the policy contains no mechanism to ensure that institutions are fully reimbursed for costs associated with providing these

oversight functions. The Draft Policy also fails to adequately account for the security, privacy, and confidentiality risks created by the mandated public posting of information regarding biosafety procedures, IBC meeting minutes, the conduct of BSL/ABSL-3 or BSL/ABSL-4 research, and incident reports.

Recommendation:

(a) Develop and include within the Draft Policy categories of lower-risk research activities that do not require IBC and/or NIH review.

(b) As previously noted, remove non-NIH funded activities from the Draft Policy's scope. Alternatively, if NIH can demonstate appropriate statutory authority to support its regulation of these actitivies, it should specify within the Draft Policy how institutions will be compensated via NIH funding mechanisms for providing the oversight functions NIH is mandating.

(c) Modify the Draft Policy to permit IBCs to calibrate the type and frequency of oversight activities to actual risks presented by research activities and to coordinate with and prevent duplication of other inspection/review efforts carried out within the institution.

(d) Develop and include with the Draft Policy more detailed research security and privacy factors that institutions can rely upon to support the redaction of confidential and/or senstive private information from minutes and incident reports prior to posting, or alternatively, require only anonymized aggregated reporting.

▪**Draft Policy Uses BMBL in More than an Advisory Capacity:** The foreword to the CDC's Biosafety in Microbiological and Biomedical Laboratories (BMBL) explicitly states that it is an "advisory document," and it is not intended to be a "regulatory document." Rather, the BMBL was intended to be a periodically updated guidance document designed to support expert risk assessment and preserve institutional discretion. Despite this caution, the Draft Policy uses the containment levels set forth in the BMBL in a regulatory manner and constricts the IBC's ability to lower containment levels without NIH approval. The fact that the current issue of the BMBL was last revised prior to the COVID pandemic reveals a major flaw in using the BMBL in such a regulatory manner, i.e., the information in the BMBL is not continuously updated to reflect the latest scientific developments.

Recommendation: NIH should clearly state in the Draft Policy that the BMBL remains an advisory document, and as such, the establishment of containment levels by IBCs and NIH will be governed by current scientific evidence and may be higher *or lower* than BMBL-suggested levels when scientifically justified. Our organizations also urge NIH to ensure that there are adequate funding and operational mechanisms in place to continuously

update the BMBL to make certain that the information it contains accurately reflects the current state of scientific knowledge.

▪**Implementation Timeline is Too Short:** The Draft Policy specifies that it will take effect six months from the date of publication of the final policy with respect to new and existing NIH-funded research and non-NIH funded research conducted at an institution that receives NIH funding. The substantial increase in the portfolio of research that must be reviewed under the Draft Policy will place tremendous strain on institutions' existing IBC and biosafety operations and more than six months will be needed to take stock of new categories of research that require review; update institutional policies, processes, procedures, workflows, and associated tools; and train researchers and staff on the new policies/procedures.
Recommendation: Our organizations urge NIH to extend the effective date to 24 months from the date on which the final policy is published to afford institutions adequate implementation time. At a minimum, NIH should extend the effective date by at least 12 months from the final policy's publication date.

▪**Draft Policy is Unclear as to How Genetically Modified Plants will be Addressed:** Unlike the current policy, the Draft Policy does not include genetically modified plants within its framework, elminating a long-standing source of containment guidance for institutions, as well as best practices for greenhouse research, growth chamber research, pollen containment, reproductive isolation, and prevention of environmental release.
Recommendation: NIH should clarify how the government plans to handle guidance regarding genetically modified plants, including whether, NIH or another federal agency, plans on issuing guidance on this topic.

▪**Policy Format is Difficult to Follow:** The Draft Policy's lack of sequentially numbered sections and subsections make it difficult to use and cite.
Recommendation: To improve user friendliness, NIH should sequentially number each section and subsection of the Draft Policy.

SPECIFIC COMMENTS

Section I, Purpose: No comments.

Section II, Scope: See comments below.

▪**Draft Policy's Scope Is Overly Broad and Not Risk-Based:** The Draft Policy applies to "reseach involving known or potential risk to human health" and any of the items listed in provisions 1-4 of the Scope Section, including "[c]ells or organisms, other than plants," containing any of the items listed in items 1-3 of the Scope Section. However, virtually all organisms/cells contain some level of microorganismal contaminination. Further, there is no universal screening process for human pathogens, and some bacteria/microorganisms pose risk to only limited segments of the population (e.g., immunocrompomised individuals). Thus, as written, the Draft Policy **essentially treats every biological agent as a biohazard**, and by doing so it applies **to virtually any organism, with the exception of plants, without regard to actual risks presented. This approach serves to divert institutional/IBC time and resources to the assessment and review of lower-risk biomedical research and unnecessarily impedes the conduct of such research.**
Recommendation: To truly make the Draft Policy risk-based, we urge NIH to limit its scope to cells or organisms, other than plants, that contain one of the items in provisions 1-3, and that are known, or likely to cause, disease in humans. For example, certain toxins and self-aggregating proteins may not pose risk to human health in the absence of LD50 thresholds and/or clear evidence of causation of disease/harm. We also urge NIH to establish categories of lower-risk research such as research conducted at BSL-1/ABSL-1 that are excluded from the scope of the policy and/or are exempt from IBC or NIH review.

▪**Items within the Scope Section that Require Clarification:** The following provisions within the scope section are confusing and would benefit from additional clarification:

- **Laboratory Settings:** The term "laboratory settings" should be defined and distinguished from the defined term "laboratory research." Specifically, the Scope section states that the Draft Policy covers "all biomedical research, in ***laboratory settings,*** involving biohazards," [***emphasis added***] but the terms "laboratory settings" and "biohazards" are not defined. Instead, the Draft Policy defines the term :"Laboratory Research" as research conducted in BSL/ABSL 1-4 containment facilities. Accordingly, the scope of the policy is unclear. For example, are arthropod containment facilities, insectaries, or greenhouses considered to be "laboratory settings"? Does the Draft Policy apply to field research?
- **Clinical Research:** It is also unclear how the Draft Policy applies to clinical research, which is traditionally subject to other oversight mechanisms (e.g., OSHA bloodborne pathogen standard, hospital

infection control committee requirements). As previously noted, the policy defines Laboratory Research in terms of research conducted at BSL/ABSL levels in containment facilities but goes on to note that clinical research does not utilize traditional biosafety levels. Indeed, the only guidance the Draft Policy provides regarding risk assessment/mitigation in clinical settings is that "precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection."

Recommendation: NIH should clarify when and how the Draft Policy applies to research conducted in clinical settings. Additionally, our organizations recommend that risk assessment/mitigation in clinical setting utilize universal precautions as a baseline, coupled with additional controls (e.g., transmission precautions) based on hazard characteristics and routes of transmission associated with the items being studied. Along these same lines, NIH should clarify IBC review requirements for clinical research under Section IV.2, and detail how they intersect with other requirements in clinical settings (e.g., OSHA bloodborne pathogen requirements, hospital infectious control requirements, etc.).

- ***In Silico* Research:** The Draft Policy is unclear as to whether *in silico* research on items listed under provisions 1-4 of the Scope Section falls under the policy's auspices.

Recommendation: NIH should clarify whether *in silico* research on items listed under provisions 1-4 of the Scope Section does/does not fall within the scope of the Draft Policy, because such research does not necessarily involve a known or potential risk to human health.

- **Applicabilty to Lower-Risk Research Activities:** The draft policy is limited to "research involving known or potential risk to human health." This limitation suggests that the Draft Policy should not apply to certain lower-risk reseach (e.g., RG1 recombinant materials, gene drive modified organisms (GDMOs), and transgeneic animals at BSL-1/ABSL-1). However, several sections of the Draft Policy appear to require institutional registration and review of these lower-risk research activities without sufficient explanation and support for such risk calibration.

Recommendation: Given that NIH intends for the Draft Policy to be risk-based, NIH should specify those categories of lower-risk research activities that are excluded from the policy's scope. If all biomedical research involving the use of biological agents is included within the

Draft Policy's scope, then institutions will be required to devote a huge amount of time and resources to reviewing and providing oversight for low-risk research activities, in exchange for limited benefit in terms of improved safety.

°Examples of Activites Included/Excluded from the DRAFT POLICY: The Draft Policy does not include examples of research that do/do not fall within the policy's scope.
Recommendation: It would be very helpful to institutions if NIH provided concrete examples of research that is (a) within the Draft Policy's scope; and (b) excluded from the Draft Policy's scope. It would also be helpful to institutions if NIH clarified whether/how the Draft Policy applies to animal pathogens and other zoonotic risks, agricultural pathogens, plant pathogens, phages, environmental organisms, prions, and other self-aggregating proteins.

°Research Regulated by Other Federal Agencies: The Draft Policy states: "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained."
Recommendation: It would be very helpful to institutions if NIH could provide details on how this approval/clearance process will work, including:

- Specifying which federal agencies will have authority over various types of pathogens (e.g., Will USDA have jurisdiction over plant pathogens and genetically modified plants?) and what process institutions will need to follow to determine who has jurisdiction.
- Specifying which agency will have ultimate oversight of biomedical research in areas where multiple agencies (e.g., CDC, OSHA, USDA) have overlapping oversight responsibilities, and how that determination will be made.
- Clarifying the meaning of the phrase "approvals or other applicable clearances" and from which agency (i.e., NIH or another federal agency) institutions are expected to obtain these approvals/clearances.

Section II, Compliance and Enforcement: No comments.

Section II, Voluntary Compliance: No comments.

Section II, General Definitions Section

▪**Overarching Comments:** Several key definitions are overly broad, thus creating uncertainty regarding the Draft Policy's scope and undercutting NIH's stated goal of a risk-based biosafety policy. Additionally, the Draft Policy redefines terms that have well-established scientific meaning, reducing the clarity and consistency needed for effective policy implementation.
Recommendation: NIH should ensure that terms are defined in line with their common usage, and revise overly broad definitions to directly align oversight requirements with actual risks presented. Comments regarding specific definitions follow.

▪**Comments on Specific Definitions:**
°**Biological Agent:** As previously noted, the Draft Policy appears to assume that every biological agent constitutes a biohazard, and definitions clarifying the boundaries between these two terms should be provided. Additionally, the term "parasite," as used in this definition, would benefit from further clarification. For example, parasites could encompass mosquitos, ticks, lice, various helminths, etc., so if the definition is referring to intracellular parasites, it should state so. Similarly, the definition should address whether it encompasses ectoparasites that serve as vectors of disease transmission, as opposed to causing disease. Finally, the definition should also be clear as to how "opportunistic pathogens" that only affect very specific segments of the population should be addressed.
Recommendation: Revise this definition to address the points outlined above.

°**Biomedical Research:** In addition to being extremely broad, this definition has the potential to introduce instability and inconsistency, as it refers to "research on a topic that is within the mission of the NIH," and thus could change dramatically over short periods of time, depending on how Congress and the Executive Branch expand or curtail NIH's mission.
Recommendation: NIH should employ a static definition of biomedical research (e.g., "Research that is conducted to increase fundamental knowledge and understanding of the physical, chemical, and functional mechanisms of human life processes and diseases"[1]) that is not tied to, and does not change with, the scope of NIH's mission.

°**Emerging Agent:** NIH's definition of this term is at odds with the definition

[1] Definition of "biomedical research," NIH, Collection Development Guidelines of the National Library of Medicine (2019; updated Sept. 25, 2025).

used by scientists, biosafety, and public health professionals, who consider an "emerging agent" to be a known agent that is emerging as a cause of disease. Further, the NIH definition inappropriately equates a newly identified organism with a pathogen.

Recommendation: NIH should replace this definition with the more commonly accepted definition outlined above. If NIH retains the current definition, it should explicitly define what "newly identified in nature" means. For example, is "newly identified" limited to a new species or genus? Additional points that should be clarified in the definition include the following:

- How would chimeras and plasmids/viral vectors/replicon systems containing genetic material from different sources be viewed?
- How are prions and self-aggregating proteins viewed?
- Does the definition encompass synucleins and preformed fibrils, or other organisms/materials on which there is not yet consensus on whether they cause human disease or are just associated with such disease?

°Genetic Modification: The proposed definition of genetic modification significantly broadens the scope of items covered by the Draft Policy. Specifically, expanding the definition of "genetic modification" to include nucleic acids that can be translated, as well as the alteration of the genome using chemical or radiological means, is inconsistent with the NIH Guidelines' historical approach to oversight of research that introduces stable genetic modifications. Genetically modified organisms **do not** inherently present greater uncertainty. In fact, many genetically modified organisms are well characterized and **present less uncertainty** than their wild-type counterparts. Indeed, the level of uncertainty associated with an organism depends on multiple factors, including the nature of the modification, the amount and quality of available data, the resulting phenotype, and prior experience with the organism. Additionally, the Draft Policy's overly prescriptive approach to genetic modifications will result in inconsistent and duplicative oversight (e.g., overlap with FDA and existing laboratory oversight requirements) and adds little to no value in terms of improved biosafety. Rather, this approach has the potential to increase risk by causing the IBC and biosafety team to "spread themselves thin" by expending time and resources on lower-risk activities, instead of focusing on research presenting higher risks.

Recommendation: NIH's new approach to viewing all genetic modifications as suspect is inconsistent with NIH's intent to develop a risk-based policy. NIH should instead incorporate into the definition of genetic modifications a provision that limits IBC review and oversight to only those genetic

modifications that present specific risk characteristics and/or consequences based on available evidence.

°**Laboratory Research:** The Draft Policy includes the terms "laboratory settings" and "laboratory research," but only provides a definition for "laboratory research," which it defines in terms of containment levels.
Recommendation: As previously noted, NIH should include a definition of "laboratory settings," a term used in the Scope Section. Our organizations also recommend that NIH clarify whether the scope of the policy is based on "laboratory settings" or 'laboratory research." Finally, given that not all "laboratory research" requires containment levels, NIH should consider renaming this term as "laboratory research requiring containment" to avoid causing confusion among scientists and biosafety personnel who commonly understand this term as any research taking place in a lab setting.

°**Research Involving Biohazards:** This term is defined in the scope section, but it does not appear in the general definitions section.
Recommendation: For consistency, NIH should include "research involving biohazards" as a defined term within the general definitions section and specify how the term relates to the setting in which such research is performed, i.e., laboratory settings.

°**Toxins:** The Draft Policy defines a "toxin" as: "[a] protein or peptide produced by living organisms that causes harm in humans." Many biological molecules may cause harm under certain exposure conditions or at sufficiently high concentrations, but absent such conditions, they may be harmless. Although the risk assessment section of the Draft Policy appropriately accounts for factors such as potency, amount used, and intracellular accessibility, these concepts are absent from the definition. Additionally, the definition does not address the potential of exceptions for naturally occurring toxins (e.g., those produced by algae, use of cephalopods, etc.).
Recommendation: NIH should incorporate objective criteria (e.g., potency, exposure potential, quantity, biological activity) into the definition of "toxin," and consider using LD50 levels as a criterion for inclusion under the Draft Policy.

Section III, Roles and Responsibilities: See comments below.

Section III-A, Responsibilities of the Institution

▪**Applicability:** As previously noted, extending the Draft Policy to non-federally funded research conducted at institutions that receive any NIH funding appears to exceed the scope of NIH's regulatory authority.
Recommendation: NIH should identify the specific statutory authority supporting the extension of the Draft Policy to non-federally funded research conducted at institutions receiving NIH funding, and absent such specific authority, limit the scope of the Draft Policy to NIH-funded research. NIH should also provide greater clarity in this section and/or in the scope section regarding exactly what entities the policy applies to (e.g., affiliated hospitals, separately incorporated research institutes, subcontractors, international sites).

▪**Biosafety Assurance:** It is imperative that Authorized Organizational Representatives (AORs) specifically understand the criteria to which they are certifying through their execution of the Biosafety Assurance. It is also important that NIH conduct the assurance process in an efficient and streamlined manner that permits institutions to begin/continue covered research without undue delay.
Recommendation: NIH should clarify the following issues in the Draft Policy:

- Is the AOR certifying that the institution has established an adequate biosafety oversight program, or certifying compliance for every individual research activity and researcher covered by the policy?
- Describe the criteria NIH will use to approve, restrict, suspend, or withdraw an Assurance.
- Provide an anticipated turn-around time for NIH' approval of an assurance.

NIH should consider patterning the Biosafety Assurance process after the assurance processes in place at the HHS Office of Human Research Protections or at the Office of Research Integrity. Additionally, it would be helpful to institutions if NIH were to provide a draft template assurance document on which institutions can submit comments.

▪**IBC Training Responsibilities:** The Draft Policy states that an institution is responsible for ensuring appropriate training regarding laboratory safety and implementation for the IBC Chair and members, biological safety officer and other containment experts, principal investigators, and laboratory staff.
Recommendation: NIH should develop and provide role-based training resources that IBCs may use to satisfy these training responsibilities.

▪**Record-keeping requirements:** The Draft Policy vastly expands the scope of research requiring IBC review/oversight, resulting in a tremendous increase in IBC-associated records (both paper and electronic) that must be developed and retained, at substantial storage and archival costs.
Recommendation: NIH should consider implementing a more limited period of record retention. Given that the Draft Policy calls for the IBC to provide *de novo* review of each research protocol every three years, our organizations suggest that NIH cap the record retention period at two review cycles (six years), thus affording transparency, while reducing administrative burden.

▪**Public Posting of IBC Related Documentation:** The Draft Policy calls for the institution to publicly post "to the maximum extent possible" the following documents/information:

- Weblinks to publicly posted institutional biosafety procedures (including but not limited to documentation detailing the IBC roles, responsibilities, authorities, and processes for how biosafety risks are managed);
- A continuously updated IBC roster;
- IBC meeting minutes;
- Incident reports;
- Synopses of relevant staff trainings provided;
- Contact information for the IBC Contact, IBC Chair, and BSO (if applicable); and
- Information regarding whether the institution conducts research in a BSL3/ABSL-3 or BSL4/ABSL-4 laboratory, research with GDMOs, has a BSO, receives NIH funding, and/or has an externally administered IBC.

This approach fails to strike an appropriate balance between the need for public transparency and the need to protect the security of laboratory facilities, the security and privacy of biosafety personnel, and proprietary and confidential information associated with non-federally funded research that now falls within the scope of the Draft Policy.
Recommendation: Our member institutions understand the need for required documentation retention for agency inspection as appropriate under the Draft Policy. Nonetheless, the need for public transparency must be balanced against the goals and requirements of privacy laws (e.g., HIPAA, state privacy laws, collective bargaining agreements) and other policy concerns (e.g., protection of trade secrets, promoting a just and fair culture of incident reporting). With respect to incident reports, which often contain sensitive personal information, NIH should permit anonymized, aggregated reporting with identifiable information disclosed to appropriate governmental officials

only when there is a legitimate need to know (e.g., public health investigation). If NIH declines to adopt anonymized/aggregated reporting, it should not require the posting of any personally identifiable information except for the names and institutional information for the IBC Contact, IBC Chair and BSO.

NIH should also specify within the Draft Policy a de-identification standard (e.g., HIPAA standard) and specify what information can be redacted from records prior to public posting to protect the security and privacy of biosafety personnel and facilities and to safeguard proprietary and confidential information associated with non-federally funded research. Further, NIH should also exempt from posting any information related to processes and procedures developed to ensure the security of covered research and the facilities in which that research is conducted. Finally, the Draft Policy should be exempt from posting any information designated as confidential or proprietary by non-federal research sponsors.

Section III-B, Responsibilities of the Institutional Biosafety Committee

▪**Overarching Concerns:** Although NIH has expressed its intent to elevate and strengthen the role of the IBC and the BSO, the Draft Policy does not clearly delegate to those parties the specific authorities necessary to carry out those responsibilities.
Recommendation: NIH should clearly delineate within the Draft Policy specific authorities of the IBC and BSO (e.g., ability to take timely action to address significant biosafety concerns, suspend research protocols, etc.). NIH should also include provisions within the Draft Policy that ensure the IBC's independent decision-making authority akin to the independent authority of IRBs and IACUCs (e.g., institution cannot reverse IBC's non-approval or suspension of a protocol).

▪**IBC Membership**: No comments.

▪**IBC Functions:** See comments below.

▪**First Sentence of Section ("The IBC, or its delegate as applicable, is responsible for"):** The first sentence's reference to "[t]he IBC, or its delegate as applicable" is confusing.
Recommendation: NIH should clarify whether the term "or its delegate" refers to an individual or subgroup of IBC members assigned to conduct "delegated reviews" under Section IV-3.

- **First Bullet Point:**
  - **Clause (3)("in cases of research involving. . . "):** The concerns noted in clause (3) relating to research involving "human subject research participants" are also applicable to animal research.
    Recommendation: Delete the text that reads "in cases of research involving human research participants."

  - **Third Sentence ("IBC oversight may conclude . . . "):** Shedding may continue after the last dose of a product is administered to human research participants, so it is unclear as to why IBC oversight should end at that point.
    Recommendation: Delete the third sentence ("IBC oversight may conclude after the last participant is administered the final dose of product") and modify the fourth sentence to read as follows: "IBCs should establish appropriate endpoints for oversight based on their biosafety assessment of the proposed research."

  - **First Sub-Bullet Point ("No member of the IBC . . . "):**: It is unclear as to who has the responsibility for determining whether an IBC member has a conflict of interest.
    Recommendation: NIH should include a statement that the IBC is empowered to establish its own processes and procedures for soliciting information from members regarding possible conflicts of interest and determining when such conflicts exist and require member recusal.

- **Second Bullet Point ("Taking IBC meeting minutes. . . "):** Requiring approval of IBC minutes "no later than [the IBC's] next convened meeting," places excess administrative burden on IBCs that meet frequently and review large numbers of protocols. Indeed, one COGR member institution has estimated based on current meeting-minute preparation time and the template content that it will be required to hire a full-time employee just to fulfill the Draft Policy's IBC meeting minutes requirements.
  Recommendation: NIH should extend the period for approval of IBC meeting minutes to "no later than ninety (90) days after the meeting at which the minutes were taken."

- **Third Bullet Point ("Notifying the PI when . . . "):** The Draft Policy calls for "de novo registration submission and review" at least every three years, however, NIH does not provide any rationale for requiring de novo review for all protocols or for selecting a three-year period, as opposed to four or five-year

period. If the Draft Policy is intended to be risk-based, then the period for review and re-registration should be based on risk posed by the research in question, as determined by the IBC.
Recommendation: NIH should modify the Draft Policy to permit the IBC to establish the re-registration period based on the risk posed by a specific research protocol. NIH should also empower the IBC to provide a re-review/re-registration grace period of up to 90 days to accommodate circumstances in which the IBC cannot complete its review within the specified period.

Alternatively, if NIH maintains the strict three-year re-registration/re-review period, it should specify within the policy what the status of a protocol is that (a) has not been reviewed/approved within the three-year period; or (b) has been reviewed but not approved within the three-year period because protocol changes are required. Additionally, NIH should clarify whether the three-year review requirement will apply prospectively (i.e., to protocols first approved by the IBC after the Draft Policy is implemented), or retrospectively (i.e., to protocols first approved by the IBC prior the Draft Policy's implementation), and if the latter, the date by which existing IBC-approved protocols must receive de novo approval.

▪**Fifth Bullet Point ("Petitioning NIH for determination of the minimum . . ."):** The circumstances in which the petition process is to be used, and the operational details of the process are unclear.
Recommendation: NIH should clarify this provision in the following respects: (a) specify whether the petitioning mechanism is limited to human pathogens; (b) allow for the possibility that no biocontainment level will be required in the case of low-risk agents; (c) establish a timeline by which NIH will address the petitions that it receives; and (d) address how IBCs should handle cases in which the organisms in question cannot be identified past the genus level.

▪**Seventh Bullet Point ("Periodically reviewing approved . . ."):** It is unclear whether the "periodic review" specified in this provision is to be carried out in addition to the de novo review.
Recommendation: NIH should clarify if the periodic review is required in addition to the three-year de novo review, and if so, provide additional details on expectations for periodic review, including specification of the protocol sections/elements that require review. Along these lines, is periodic review necessary with a three-year de novo review requirement? If the 3-year de novo review requirement is maintained, NIH should consider the USDA's review

approach, which requires 3-year de novo review, but removed a previous requirement for annual continuing review. [9 CFR §2.31].

▪**Eighth Bullet Point ("Adopting plans which include . . . "):** The Draft Policy is unclear as to whether the IBC must formally adopt any institutional emergency response plans, many of which address areas outside of the IBC's scope.
Recommendation: NIH should clarify whether the IBC must formally adopt all institutional emergency response plans (i.e., in a manner similar to that in which protocols are approved), or whether IBC or BSO review of/consultation regarding the portions of institutional emergency response plans impacting IBC-regulated areas is sufficient.

▪**Tenth Bullet Point ("Reporting certain incidents . . ."):** The first sentence of this section states that reporting is required for incidents that pose a significant risk to human health. However, this modifying phrase is absent in the description of individual incidents that must be reported, thus creating confusion. For example, why would the lack of registration of a human cell line require 24-hour reporting, particularly if a lab were functioning at BSL2? Further, under the fourth sub-bullet point ("Any incidents involving exposures at BSL-2/ABSL-2) . . ."), it is unclear whether minor exposure to an agent not known to cause disease or a non-treatable BSL2 exposure requires reporting. Overall, the lack of clear reporting criteria and thresholds in this section will result in inconsistent reporting practices. For example, a non-biological occupational injury (e.g., back strain) that occurs inside a BSL-3 laboratory could technically be considered a "incident at a BSL-3 facility," but have no biosafety implications. Finally, the term "adventitious agent" (as used in the last sentence of this section) is undefined.
Recommendation: NIH should empower the IBC to determine in its policies and procedures which types of reported incidents require committee-level review, and which can be handled via reporting to and review by the BSO. Further, our organizations urge NIH to explicitly state that incidents are reportable to NIH only when the IBC determines that they are biologic in nature and pose a significant risk to human health, by making the following modifications to this section:

- **First Sentence:** Modify this sentence to read as follows: "Reporting certain incidents to NIH that the IBC has determined are biologic in nature and pose a significant risk to human health using the required reporting template.

- **Third Sentence:** Modify this sentence to read as follows: "This includes the incidents involving the factors listed below when the IBC has determined such incident is biologic in nature and poses a significant risk to human health:"
- **Fourth Sub-Bullet Point:** Clarify whether exposure to an agent not known to cause disease or untreatable exposures at BSL-2/ABSL-2 that the IBC has determined do not pose a significant risk to human health are reportable.

NIH should provide examples that clearly distinguish reportable and non-reportable events to promote consistent interpretation and reporting. Finally, NIH should include a definition for "adventitious agents" in the General Definitions section.

▪**Eleventh Bullet Point ("Reviewing certain lower-risk incidents . . . "):** If NIH intends for this policy to be a risk-based policy and to empower the IBC and BSO to provide appropriate oversight, it is unclear (1) why any incidents at BSL-1/ABSL-1 require mandatory reporting to/review by the IBC, as opposed to being handled via interaction with the BSO, with reporting to the IBC as the BSO determines is appropriate in accordance with institutional/IBC policies and procedures.

Recommendation: NIH should modify this bullet point and its two sub-bullet points to remove any references to BSL-1/ABSL-1 and to instead include the following statement:

> Incidents at BSL-1/ABSL-1 that (a) do not involve recombinant technology; and/or (b) that involve minor spills of low-risk agents that do not breach containment and that are properly cleaned and decontaminated in accordance with institutional policies and procedures, shall be handled by the researcher in conjunction with the BSO. The BSO shall report to the IBC any such incidents that require reporting under applicable institutional and/or IBC policies and procedures.

▪**Twelfth Bullet Point ("Posting all incident reports .. . . "):** This provision is unclear as to whether public posting is required for incidents that are not required to be reported to NIH.

Recommendation: NIH should modify the first sentence of this provision to read as follows: "Posting of all incident reports for those incidents that are required to be reported to NIH on a public-facing webpage on the website of the institution, using the required incident reporting template."

Biological Safety Officer: As written, the Draft Policy increases the BSO's responsibilities without a corresponding increase in authority or recognition of the subject matter expertise necessary to carry out the BSO's duties.
Recommendation: NIH should define the BSO's authority (e.g., authority to stop work conducted under an IBC approved protocol that poses a significant risk to human health), in addition to detailing responsibilities. Alternatively, the Draft Policy should make clear that the institution is empowered to delegate such authorities to the BSO as are necessary to carry out the responsibilities listed in the Draft Policy. Additionally, NIH should detail any minimum qualifications/competencies that it expects the BSO and/or "other official" assigned to take on these responsibilities to possess. Finally, it was noted that NIH eliminated large scale work (i.e., >10 L) as an independent trigger requiring a BSO, and questions were raised by our members as to whether this was an intentional omission.

Section, III-C, Responsibilities of the Principal Investigator: This section should make clear that the PI's responsibilities must be carried out within the framework of IBC and institutional policies and processes.
Recommendation: NIH should modify the first sentence of this section to read as follows: "The responsibilities of the PI include following all institutional and IBC policies and procedures including those governing the following duties:"

Section III-D, Responsibilities of the National Institutes of Health (NIH): The Draft Policy lists NIH responsibilities, but it lacks processes that NIH will follow in carrying out these responsibilities, including applicable timelines. Additionally, this section fails to include clear mechanisms for how NIH will directly communicate with assured institutions and registered IBCs.
Recommendation: NIH should provide details on the processes that it will follow in carrying out its responsibilities under this section, including associated timelines, particularly with respect to when NIH will provide decisions regarding containment levels, Biosafety Assurances, and incident reports. NIH should also include within its listed responsibilities an obligation to directly communicate with all assured institutions and registered IBCs regarding proposed policy changes and interpretations and provide ample time for comments. Additionally, NIH should establish a central webpage where all containment and other IBC-related determinations are posted.

Section IV, Categories of Oversight for Research Based on Risk: See comments below.

Section IV-1, Research that Requires NIH and IBC Approval Before Initiation: This section of the Draft Policy specifies the research and requests that must receive NIH approval, but it fails to provide details regarding the operational process for making these requests or how NIH will conduct its scientific review. Further, this section lacks any information concerning the timeline for decision-making by NIH, as well as any circumstances that warrant expedited decision-making.

Recommendation: NIH should provide templates outlining the information to be provided to the agency in connection with (a) review of research involving emerging/novel/zoonotic agents for which the risk group (RG) classification or minimum containment level is not available in the BMBL; (b) initial requests to lower containment for research involving wild type or genetically modified RG3 or RG4 biological agents; and (c) initial requests to lower containment below BSL-2 for research involving gene drive modified organisms (GDMOs). Additionally, NIH should consider initially spelling out the acronym "GDMO" and providing a definition for this term.

To assist institutions and IBCs in better understanding and preparing for the determination process, NIH should also detail how it will conduct its scientific review process, including a description of who will be involved in the process and their subject matter expertise, along with the objective assessment criteria that will be employed. Additionally, NIH should set forth expected review periods, including circumstances that justify expedited review requests, along with a process for IBCs/institutions to obtain status updates, and an escalation mechanism for when a determination is delayed beyond the stated period. Finally, NIH should also clarify whether an institution may proceed with research under interim containment requirements established by the IBC, pending receipt of the NIH determination.

Section IV-2, Research that Requires IBC Review and Approval Before Initiation: The research category listed under the fourth bullet point – "Research with primary cells that may be contaminated by adventitious agents" – is overly broad and includes research posing low-level risks that do not warrant mandatory review by the full IBC. For example, this category encompasses human primary cells, human tissues, human blood-derived materials, non-human primate tissues, and other primary materials that are routinely handled using universal precautions and/or following institutional exposure control plans/occupational health programs and OHSA requirements related to bloodborne pathogens.

Recommendation: As previously noted, NIH should include a definition for the

term "adventitious agents." Additionally, NIH should limit the scope of this category to primary cells with known or reasonably suspected contamination by adventitious agents that require specialized containment or response measures beyond universal precautions/OSHA bloodborne pathogen requirements. If NIH rejects these recommended limitations, it should, at the very least, allow for delegated review of activities falling within this category that are routinely conducted in accordance with established institutional controls.

Section IV-3, Research that Requires Review and Approval Before Initiation and May be Delegated to an Individual or Subgroup of IBC Members: The Draft Policy (a) omits the category of Exempt Experiments included in Section III-F of the current NIH Guidelines; (b) omits the category of low-risk experiments requiring only notice to the IBC under Section III-E of the NIH Guidelines; and (c) omits any exemption for transgenic rodents housed at ABSL-1. Instead, the Draft Policy requires delegated review for these low-risk activities resulting in a vastly increased IBC workload and unnecessarily hampering research activities without a corresponding increase in safety benefits. Rather than focusing on allocating IBC efforts and resources to higher-risk activities, the Draft Policy directs limited IBC, institutional, and agency resources to the review of research activities that pose so little risk that they would not even fall within the ambit of a truly risk-based policy.
Recommendation: As NIH has stated, a major goal of the Draft Policy is to establish a risk-based regulatory approach. Accordingly, NIH should retain the categories of exempt experiments and experiments requiring only notice to the IBC simultaneously with initiation as described in Sections III-E and III-F of the current NIH Guidelines.

Section V, Risk Assessment and Mitigation for Research Involving Biohazards: As previously noted the Draft Policy appears to inappropriately equate the terms "biohazard" and "biological agent," by requiring a risk assessment for "research involving ***biohazards***," but only providing a definition of the term "***biological agent.***" Additionally, the Draft Policy significantly expands the categories of research that fall within its scope, but it provides limited operational guidance that IBCs and institutions can use to ensure that mandated risk assessments are performed in an objective and consistent manner. The Draft Policy includes factors to consider in risk assessments, but it lacks any decision-making frameworks that IBCs can use when evaluating these risks and developing risk mitigation strategies. Finally, the use of the word "manipulation" in the phrase "Manipulations of the biohazard," is

confusing because manipulation can be used to refer to either changing the characteristics of the agent (which is addressed elsewhere in the policy) or the physical handling of the agent, which is the topic of this section.
Recommendation: As previously noted, NIH should provide a definition of the term "biohazard" that distinguishes it from "biological agent." NIH should also develop and provide additional tools that IBCs can use to promote objective and consistent risk assessments such as frameworks discussing how risks and benefits should be weighed and evaluated, sample containment determination examples, sample risk mitigation plans, case studies, and FAQs. Finally, NIH should replace the word "manipulations" with "handling."

Section V-A, Requirements and Consideration for Risk Assessment of the Characteristics of the Biohazard: No comments.

Section V-B Requirements and Consideration for Risk Assessment for Genetically Modified Biological Agents, Cells, or Organisms: No comments.

Section V-C, Requirements and Considerations for Risk Assessment for Synthetic Biological Agents or Emerging Technologies: No comments.

Section V-D, Requirements and Considerations for Risk Assessment of Manipulations of Biohazards: As previously noted, to avoid confusion, NIH should replace the word "manipulations" in this section with "handling."

Section V-E, Risk Mitigation Strategies and Laboratory Containment: As previously noted, in some cases GDMOs may be more stable than wild-type organisms, and thus it is unclear why the Draft Policy requires a minimum of BSL-2 for all research involving GDMOs.
Recommendation: NIH should delete the minimum BSL-2 containment requirement for GDMOs and empower IBCs to set an appropriate containment level based on the characteristics of the GDMO.

IBC Meeting Minutes Draft Template: The meeting minutes templates is overly detailed and prescriptive and serves only to impede minutes preparation by requiring reiteration in the minutes of details that are already included in other documentation (e.g., standard operating procedures, research protocols). Further, given that the Draft Policy encompasses non-NIH funded research conducted at institutions that receive NIH funding, the Draft Policy inadequately addresses the types of redactions that are appropriate in cases in which an institution's conduct of non-NIH funded research is subject

to confidentiality and non-disclosure obligations. Finally, the required level of detail in the minutes makes it extremely difficult, if not impossible, for institutions to meet the Draft Policy's deadline for having minutes prepared by the next convened IBC meeting, particularly at institutions that have multiple IBCs meeting frequently.

Recommendation: Our organizations urge NIH to withdraw the required template approach, and instead follow the approach to meeting minutes adopted by the Common Rule, and require only that the institution or IBC "prepare and maintain adequate documentation of all [IBC] activities" including "Minutes of [IBC] meetings, which shall be in sufficient detail to show attendance at the meetings; actions taken by the [IBC]; the vote on these actions including the number of members voting for, against, and abstaining; the basis for requiring changes in or disapproving research; and a written summary of the discussion of controverted issues and their resolution." [*See*, 45 CFR §46.115]. If NIH maintains the template approach, the agency should consider making the following changes to the template and process for keeping minutes:

- **Timing:** Allow for 90 days to prepare meeting minutes.
- **Redaction Principles:** The NIH's redaction standards do not take into account the fact that the Draft Policy encompasses research that NIH does not fund and that is frequently being conducted pursuant to a contract with a private entity that impose confidentiality and non-disclosure obligations on the institutions carrying out the research. These confidentiality and non-disclosure requirements often include proprietary or pre-patent information that is critical for IBC review, but the public disclosure of which has significant financial and legal implications for the sponsor. Our organizations remain concerned that NIH's inclusion of non-NIH funded research within the scope of the Draft Policy is inappropriate and without statutory authority. Should NIH continue with this approach, our organizations urge the agency to recognize within the template that institutions may cite contractual standards governing non-NIH funded research as the basis for redactions made in meeting minutes. To do otherwise would constitute undue interference with an institution's ability to contract with private entities to carry out research, merely because the institution accepts NIH funding on unrelated projects.
- **Incident Review**: It should be sufficient to include within meeting minutes the same level of detail regarding incidents that is required in public posting of those incidents.

Draft Incident Reporting Template: As with the minutes template, the incident reporting template is overly detailed and prescriptive, and requires the disclosure of information that may compromise the privacy of an individual involved in an incident and the security of research activities. Further, the requirement to publicly post such detailed information, including "root cause analysis," serves to discourage incident reporting and goes against efforts to replace a "blame culture" of incident reporting with a "fair and just culture" approach that facilitates and supports self-reporting.

Recommendation: Our organizations recommend that NIH abandon the mandated template (which is not in effect for either IRBs or IACUCs) and permit anonymized aggregated incident reporting. Alternatively, NIH should require institutions to only report on incidents that pose a significant risk to human health by supplying sufficient detail to provide notice of the event and follow-up corrective actions taken. If NIH retains the proposed incident reporting template, the agency should consider making the following changes:

- **Required Reports:** NIH should reference the provisions of Section III-B of the Draft Policy with respect to the incidents that must be reported instead of repeating this information in the template. The repeated information adds confusion, not clarity (e.g., "administrative failure" description is too broad to be helpful). Further, as previously noted, NIH should limit the incidents required to be reported to those that the IBC determines are biologic in nature and pose a significant risk to human health. This point should be made clear in the form instructions and in the section on incident information. NIH should also clarify if the reporting template is only used for reports to NIH, or if it must be used for internal institutional reporting as well.
- **PI's Name and Grant Information:** Remove the requirement for providing the PI's name, particularly if public posting is required. In labs that have only one or two workers, the posting of the PI's name could lead to identification of the person involved in the incident. For the same reason, grant information that can be used to identify the PI also should be removed prior to publication.

Conclusion: Our organizations appreciate the opportunity to provide comments on the Draft Policy. Our member institutions support robust biosafety review and oversight but have expressed concerns that the Draft Policy tilts too far in the direction of requiring numerous and complicated controls for low-risk research. Such an approach does not serve the cause of increased biosafety because it misallocates ever-more limited resources away

from the oversight of higher-risk activities, while unnecessarily burdening the conduct of low-risk activities. Accordingly, NIH should consider recalibrating its approach by modifying the Draft Policy to better enable IBCs and BSOs to provide independent, risk-based review and oversight. The recommendations expressed above will help to foster such an approach.

Finally, our organizations request that prior to the publication of a final policy, NIH will post for comment a revised draft of the policy that includes a summary of the comments it received and its basis for accepting/rejecting those comments.

269. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Not Applicable

Role: Other

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Definition of "biohazards" requires significant clarification and examples
The Policy defines research involving biohazards as "research involving known or potential risk to human health and any of the following:
1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above."
NIH should provide examples to clarify the phrase "known or potential risk to human health." This phrasing as provided is far too broad and open to interpretation. What level of risk would be considered significant, or is any risk, no matter how small, subject to the Policy's oversight? For example, wild-type Risk Group 1 agents are excluded from the Policy, presumably because of a lack of risk to human health; but it is unclear if a genetically modified Risk Group 1 agent expressing only a reporter transgene would be considered a biohazard under the Policy and who is meant to make that determination. The existing NIH Guidelines contain specific Exemptions where the agents in use do not present a significant risk to health or the environment (e.g., E. coli K-12, S. cerevisiae, certain activities involving transgenic rodents, etc). It is unclear if these organisms would be Exempt when genetically modified under the new Policy. Similarly, it is unclear if all primary cells and cell lines (including, for example, murine or insect cells) are included within the Policy scope, or only those that harbor human infectious agents.

Definition of "toxin" requires refinement
The Policy defines Toxin as "A protein or peptide produced by living organisms that causes harm in humans." This definition is far too vague. First, not all biological toxins are proteins or peptides (e.g., T-2 toxin); are such toxins excluded from the policy's oversight? Second, describing a toxin as any protein that "causes harm in humans" includes other protein classes that are not toxins (e.g., oncogenic proteins, allergens). NIH should refine this definition and should include reference to a practical LD50, as the scientific standard for classifying toxicity.

Definitions of “emerging agent or organism” and “zoonotic” require clarification
The definitions of “emerging agent or organism” and “zoonotic” require significant clarification and examples to ensure they are reasonably applied, especially given the Policy’s requirement for NIH review and input for any research involving an emerging or zoonotic agent without a current RG or containment level classification. As written, the definitions for these agent categories are extremely broad and would be difficult to apply in practice. For example, would studies that involve screening environmental samples for previously unidentified organisms or strains require NIH review for each strain identified? At what point in such research would NIH review be required: at the initiation of the work because there is a chance of identifying a new agent, or only after the agent has been fully characterized and deemed both novel and potentially pathogenic? What constitutes a “newly identified” agent? Must it be a species that has not been published in literature? What about new strains of previously known species? What qualifies as “reasonable suspicion” of transmission from animals to humans? Such questions about practical application of the definitions limit their utility and may lead to overwhelming need for NIH input on relatively low risk (BSL-2) studies. We suggest that NIH limit the definitions to organisms with potential for serious or lethal human disease, as assessed by the PI in consultation with the IBC. We also request clarification regarding expected oversight for studies involving screening or culture of unknown organisms from clinical or environmental samples.

Clarify “biomedical research” definition and supply a definition of “research”
The Policy’s definition of “biomedical research” under its scope is written as “research on a topic that is within the mission of the NIH, including applicability to: research supported by NIH, and non-NIH funded research that is conducted at an institution that receives any NIH funding.” NIH should update the definition to address the following gaps.
First, NIH should clarify what is meant by “non-NIH funded research”. As written, it is unclear if this refers to any research that is not funded by the NIH, or any funded research that is not funded by the NIH.
Second, NIH should take this new Policy implementation as an opportunity to clarify a definition of “research.” Biohazards are used in many different non-research projects, such as teaching, clinical testing, or manufacturing. While safety is necessary for all biohazard handling, the oversight structures of this Policy are specific to research and should be clarified as such with a definition of research. As a model, human subjects research requiring Institutional Review Board (IRB) review has clear and established definitions of both “human subjects” and of “research”.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Refining definitions is necessary to ensure oversight is calibrated to risk
As stated previously, NIH must refine and provide examples for terms including “biohazards”, “emerging agents”, and “zoonotic” to ensure it is clear what level of human health risk is truly relevant to the new Policy. This clarification should help to ensure that the tiered oversight structure in the new Policy is properly calibrated to risk. Additional terminology that is unclear or appears to require excessive review is listed below. NIH should provide examples of what falls within these terms and what does not for consistent application of the Policy:
- “Primary cells that may be contaminated with adventitious agents”: By definition, primary cells are less well-characterized than other cell lines. Primary cells collected from laboratory rodents that have not been treated with infectious agents should not require full IBC review.
- “Transgenic organisms”: Clarify the difference between “genetically modified” and “transgenic” for oversight purposes.

- “Reporter or low-risk transgenes”: Provide examples for consistent implementation.
- “Well-characterized cell lines”: What qualifies as “well-characterized”?

3. Continued utility of Risk Groups: Risk Group lists must be frequently updated and publicly shared by NIH

Reliance on Risk Groups as a baseline for risk assessment is acceptable, as this practice is already widespread and allows a base level of consistency between institutions. However, because the Policy continues to depend on Risk Groups and requires NIH input for Risk Group determination, the NIH must publicly share and frequently update Risk Group lists based on requests for input from institutions. This practice of sharing all Risk Group determinations publicly at the federal level will promote consistency across institutions, while reducing administrative burden at both institutional and federal levels for review of identical agents from multiple institutions.

Clarify the role of the BMBL as an advisory document

The existing NIH Guidelines contain requirements for various biosafety levels, which the new Policy removes in favor of aligning biosafety levels with those described in Biosafety in Microbiological and Biomedical Laboratories (BMBL). We support this change as it helps to reduce redundancy and/or conflict between biosafety level definitions applied by different agencies. However, we believe the new Policy should clarify its expectation in use of the BMBL as an advisory document. The BMBL was not written as a policy requirement. While it provides an excellent framework for best practice, institutions should be able to adapt and deviate from the BMBL when justified and appropriate for their specific circumstances.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public posting of individual incident reports will create privacy issues, increase administrative burden, and reduce reporting rates.

We have significant concern regarding the requirement for public posting of individual incident reports, especially given the level of detail included in the required Incident Reporting template and the minimal immediate value in public reporting on low-risk incidents. While we agree with the aim of transparency and the value of consistency in reported data across institutions, we do not see these values truly enhanced by public reporting of individual incidents on institutional websites for the following reasons:

- The Policy includes development of a National Biosafety Data and Safety Analysis Center where all NIH-reportable and voluntarily submitted incident reports would be aggregated, de-identified, and analyzed. This Center provides true value in advancing the metascience of biosafety by centralizing incident data. Institutionally posted incident reports do not add to that goal.
- Short summaries of incidents are already included for required public posting in IBC Meeting Minutes according to the required template. If the goal of posting individual incident reports is to ensure public awareness, posting of IBC Meeting Minutes already meets this need, making posting of individual Incident Reports redundant.
- Regardless of the ability to redact names from incident reports, we are concerned that posting of individual incident reports will violate privacy of those involved. At smaller institutions or in smaller research labs, listing an individual’s job title effectively identifies that individual. We have significant concern about the implications of this for protecting individual health information.

- Instead of providing value, we strongly suspect that researchers may view incident report posting as punitive and that this requirement will significantly decrease the number of incident reports notified to biosafety programs, thus directly reducing biosafety programs' ability to promote the safety that the Policy aims to support.

We instead suggest an alternative approach to strike a balance between immediate transparency, institutional administrative burden, and advancement of biosafety:

- If the goal of incident report posting is to improve biosafety and increase public transparency, we believe the required reporting structure for NIH-reportable incidents and collection of data in the National Biosafety Data and Safety Analysis Center, without institutional posting of individual reports, meets this need for NIH-reportable incidents.
- Non-NIH-reportable incidents are lower risk, thus making immediate posting for public transparency of limited value and a potentially high administrative burden. We propose that institutions instead be required to post or provide to NIH an annual summary of these lower risk incidents at their institutions. This would be similar to annual reporting of OSHA recordable incidents. This process would remove the privacy concerns around posting individual reports, while maintaining a focus on transparency and accountability to the public and encouraging institutions to periodically evaluate their incident data for trends, thus promoting continuous improvement.

24-hour notification for compliance violations is not reasonable or valuable

The new Policy codifies immediate (i.e., within 24 hours) notification for certain types of incidents, which has been the expected practice under the existing NIH Guidelines for high-risk incidents. However, the new Policy stipulates required immediate notification for all NIH-reportable incidents, including "any compliance violations at any BSL/ABSL". Compliance violations that do not also involve a serious incident should require the standard 30-day reporting only. This reduces the administrative burden on reporting these cases when there is no immediate risk resulting from the violation, while maintaining a standard of reporting all compliance violations to the NIH.

Incident Reporting Template should not require funding information

The Incident Reporting Template includes fields for NIH grant number, NIH funding institute, and NIH program officer. We do not see the value in including this information in incident reports and suspect it will be perceived as punitive, leading to fewer incident reports and undermining the safety culture that the Policy aims to support.

IBC Meeting Minutes Template should be recommended, not required

Requiring a specific IBC Meeting Minutes template creates an administrative burden and compliance challenge that does not directly support safety or transparency. While we can see value in a shared format across institutions, this value does not outweigh the administrative burden of updating existing, functional systems to match a specific template. We suggest instead that the Meeting Minutes Template be provided as a recommended resource, as was done in 2025 when the requirement for public posting of meeting minutes went into effect. To support the recommended template, there should also be a clear list of the minimum required information to help institutions meet compliance requirements. No other similar compliance committee (e.g., IRB, IACUC) has a required meeting minutes template at the federal level.

6. Other feedback relevant to this resource: Implementation timeline is too short

The 6-month implementation timeline is far too short. The Policy significantly expands scope from the

prior NIH Guidelines, and effective implementation will require institution-wide policy changes, development of new procedures and forms to match required templates, and re-education of campus stakeholders. As a public academic institution, many of our campus processes are influenced by fiscal or academic year calendars, making a timeline of less than one year impractical. We request at least one year, as has been typical for other new federal biosafety policies in recent years.

Supporting materials should be provided for Biosafety Assurance documentation
NIH should supply an example of the Biosafety Assurance documentation to aid institutions in meeting this new requirement. This resource would be akin to the Assurance Sample Document provided by OLAW for verifying compliance with the Policy on Humane Care and Use of Laboratory Animals.

270. Benaroya Research Institute

I am responding: On behalf of an organization

Name:

Name of Organization: Benaroya Research Institute

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Immune Disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Concern with expectations for minutes approval no later than the next convened meeting
This expectation removes flexibility that IBCs and administrators need to accommodate researchers. Two scenarios illustrate the burden.
1. When the IBC convenes an ad hoc meeting to approve time-sensitive research ahead of its regular schedule, administrators have less time to finalize the previous meeting's minutes.
2. When a regularly scheduled meeting has a full agenda with multiple registrations or complex amendments, IBCs often defer minutes approval so that all research items can be reviewed in the allotted time.
We respectfully request NIH to consider the following:
1. A fixed deadline for minutes approval adds administrative burden without advancing the safe, responsible, and secure conduct of research.

Draft Incident Reporting Template
There are numerous areas needing further details or clarification including:
1. Who is responsible for completing the form: the PI, the IBC, or other institutional staff.
2. What information is required for immediate reporting.
3. What type of incidents fall into this “significant risk to human health” category.
4. Reportable incidents include "administrative failures" but does not define the term, provide examples or explain when such failures must be reported. Rather than referring broadly to a section of the Policy, the template should use the Policy's own language so it’s clear what is immediately reportable.

5. The draft does not make clear whether NIH-reportable incidents or all incidents including lower-risk incidents require reporting to NIH or posting on the institution's website.
6. A template asks whether the incident occurred during NIH-funded research and requests the grant or contract number. Because laboratory personnel may perform tasks that support multiple funded projects, or none, attributing an incident to a single award may not always be straightforward. We request that NIH clarify how institutions should respond in these cases.
We respectfully request NIH to consider the following:
1. IBCs post only those incidents that pose significant risk to human health.
2. There is clear responsibility surrounding incident reporting.
3. To provide a definition and examples of what constitutes “significant risk to human health”.
4. No incident reporting is required if administrative failures do not pose significant risk.

Draft Meeting Minutes Template
NIH states that minutes should serve as the institution's record of IBC proceedings and document for NIH and the public that the IBC is fulfilling its biosafety review and oversight responsibilities. The level of detail the template requires goes well beyond that purpose, and it is not realistic for institutions whose administrative staff serve in multiple roles and are not biosafety subject-matter experts. For example:
1. Several sections duplicate information already captured in the IBC application, (e.g., project overview, risk assessment, discussion, training).
2. Staff must copy content into the minutes which adds effort without oversight value.
3. Duplicate information is entered when projects are approved through delegated review and would be reported both in the review of prior business section and in the project-specific overviews.
We respectfully recommend NIH to consider the following:
1. Minutes are meant to summarize what the IBC reviewed and the actions it took, demonstrating that it fulfilled its duties. They are not meant to recreate the meeting or serve as a transcript.
2. Allow IBCs to continue with their own minutes template summarizing the project, discussion, action and oversight responsibilities without requiring administrators to reproduce protocol applications in the minutes.

6. Other feedback relevant to this resource: N/A

Subject: Response to the Draft NIH Biosafety Policy for Research Involving Biohazards

Please consider our response to the Draft NIH Biosafety Policy for Research Involving Biohazards. We've broken the comments down into 3 sections for easier review.

Minutes approval no later than the next convened meeting

This expectation removes flexibility that IBCs and administrators need to accommodate researchers. Two scenarios illustrate the burden.

1. When the IBC convenes an ad hoc meeting to approve time-sensitive research ahead of its regular schedule, administrators have less time to finalize the previous meeting's minutes.
2. When a regularly scheduled meeting has a full agenda with multiple registrations or complex amendments, IBCs often defer minutes approval so that all research items can be reviewed in the allotted time.

We respectfully request NIH to consider the following:

1. A fixed deadline for minutes approval adds administrative burden without advancing the safe, responsible, and secure conduct of research. If a timeframe is needed, we request 30 days after approval by the IBC to be better managed.

Draft Incident Reporting Template

There are numerous areas needing further details or clarification including:

1. Who is responsible for completing the form: the PI, the IBC, or other institutional staff.
2. What information is required for immediate reporting.
3. What type of incidents fall into this "significant risk to human health" category.
4. Reportable incidents include "administrative failures" but does not define the term, provide examples or explain when such failures must be reported. Rather than referring broadly to a section of the Policy, the template should use the Policy's own language so it's clear what is immediately reportable.

5. The draft does not make clear whether NIH-reportable incidents or all incidents including lower-risk incidents require reporting to NIH or posting on the institution's website.
6. A template asks whether the incident occurred during NIH-funded research and requests the grant or contract number. Because laboratory personnel may perform tasks that support multiple funded projects, or none, attributing an incident to a single award may not always be straightforward. We request that NIH clarify how institutions should respond in these cases.

We respectfully request NIH to consider the following:

1. IBCs post only those incidents that pose significant risk to human health.
2. There is clear responsibility surrounding incident reporting.
3. To provide a definition and examples of what constitutes "significant risk to human health".
4. No incident reporting is required if administrative failures do not pose significant risk.

Draft Meeting Minutes Template

NIH states that minutes should serve as the institution's record of IBC proceedings and document for NIH and the public that the IBC is fulfilling its biosafety review and oversight responsibilities. The level of detail the template requires goes well beyond that purpose, and it is not realistic for institutions whose administrative staff serve in multiple roles and are not biosafety subject-matter experts. For example:

1. Several sections duplicate information already captured in the IBC application, (e.g., project overview, risk assessment, discussion, training).
2. Staff must copy content into the minutes which adds effort without oversight value.
3. Duplicate information is entered when projects are approved through delegated review and would be reported both in the review of prior business section and in the project-specific overviews.

We respectfully recommend NIH to consider the following:

1. Minutes are meant to summarize what the IBC reviewed and the actions it took, demonstrating that it fulfilled its duties. They are not meant to recreate the meeting or serve as a transcript.
2. Allow IBCs to continue with their own minutes template summarizing the project, discussion, action and oversight responsibilities without requiring administrators to reproduce protocol applications in the minutes.

RE: UC Comments in Response to NOT-OD-26-112, "Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards"

Dear Sir or Madam:

We write on behalf of the University of California (UC) with regard to the Request for Comment on the Draft National Institutes of Health Biosafety Policy for Research Involving Biohazards issued on August 19, 2026 (Draft NIH Biosafety Policy). The UC is comprised of ten campuses, six academic health centers, an Agriculture and Natural Resources division, 21 health professional schools, and three affiliated U.S. Department of Energy national laboratories.

UC stands at the forefront of cutting-edge research and technology development. As a system, UC receives approximately $7.5 billion annually of extramural awards to support research conducted throughout all UC locations. UC is awarded more NIH and National Science Foundation (NSF) funding than any other institution in the country.

While UC welcomes several aspects of the Draft NIH Biosafety Policy, including a simplified review structure and terminology, greater transparency through a public incident database, and the addition of delegated review, there are several concerns that need to be addressed before full implementation. As the Policy is refined, we encourage NIH to promote consistent interpretation across institutions and ensure that communication and review requirements do not unnecessarily delay research. Given the longstanding role of the NIH Guidelines for Recombinant and Synthetic Nucleic Acids in institutional biosafety programs, clear and practical requirements will be essential for successful implementation of the new Policy.

UC recognizes that the Policy is intended to be less prescriptive, however, it is too ambiguous and lacks detail for consistent application across institutions. NIH should provide examples as well as optional implementation tools and supplemental guidance documents that institutions may choose

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

to use. In addition to the specific comments provided below, UC supports and endorses the comment letter submitted by Campus Safety, Health, and Environmental Management Association (CSHEMA) on October 12, 2026 in response to this request for comment.

1. Define and narrow policy scope to apply oversight proportionate to the risk.

Scope Ambiguity: The Policy requires significant clarification regarding its scope and applicability before it can be implemented consistently and effectively across institutions. As currently written, shown below, the scope is ambiguous about which activities fall under the Policy:

The NIH Biosafety Policy covers all biomedical research, in laboratory settings, involving biohazards.

For the purpose of the scope of this Policy, research involving biohazards is defined as research involving known or potential risk to human health and any of the following:

1. *Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;*
2. *Cells, viruses, or organisms, other than plants, that have been genetically modified;*
3. *Toxins, prions, and other self-aggregating proteins; or*
4. *Cells or organisms, other than plants, containing 1, 2, or 3 above.*

It is unclear whether the Policy is intended to focus solely on research involving biological agents that pose a direct risk to human health, or whether it broadly applies to all biological materials and research activities, with the sole exclusion of plants. NIH should provide examples illustrating how the scope applies to common categories of research, including synthetic biology, computational or *in silico* design, plants, arthropods, animal pathogens, toxins, and non-infectious or non-replicating materials.

Risk-Proportionate Thresholds: If the intent is to include all biomedical research involving biological agents, the Policy would represent a substantial expansion of oversight into many research activities that are historically considered low risk. Expanding oversight would significantly increase administrative burden without a demonstrated improvement in biosafety outcomes. A limiting threshold should be added such that covered work must present a credible, scientifically plausible risk of causing disease in healthy adult humans under reasonably foreseeable laboratory exposure routes and quantities. Consideration should be given to reduce the scope of the Policy by removing oversight of toxins, self-aggregating proteins, genetically modified Risk Group 1 organisms, and other low risk activities that were exempt under the previous version of the NIH Guidelines for Recombinant or Synthetic Nucleic Acid Molecules.

Non-Human Health Risks: If NIH intends the Policy to address risks beyond human health, it should establish a separate and clearly defined threshold for credible environmental,

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

agricultural, ecological, or animal-health consequences. Those risks should not be incorporated into the Policy through undefined or open-ended references to "biohazards".

Applicability to Non-NIH Funded Research: Because this Policy functions as an institution-wide regulation, it may impose significant compliance obligations on non-NIH funded research. The Policy should either limit applicability to NIH-supported research, or define clear boundary conditions for affiliates, tenants, leased space, and core facilities.

2. Clarify and standardize definitions and terminology throughout the Policy.

The Policy contains numerous terms that are either undefined, inconsistently defined, or insufficiently detailed for reliable implementation across institutions. Given the Policy's flexible structure, NIH should provide resources explaining key terms that are likely to produce inconsistent institutional interpretations. These resources should include examples and, where appropriate, criteria for determining when an activity falls within or outside a defined category.

Undefined Terms: The Draft Policy contains numerous undefined terms, which is problematic because the lack of a definition is cause for inconsistent interpretation across institutions. Accordingly, the following terms must be defined in the final Policy: "authorized organizational representative," "biohazard, "biohazardous," "biological toxin protein," "biosafety officer," "GDMO," "primary cells that may be contaminated by adventitious agents," and "well-characterized cell lines." For clinical research, additional terms requiring definitions include "shedding," "replicating," "integrating," "higher risk manipulations," and "product."

Inconsistent Use: The term "biological agent" is used inconsistently throughout the Policy. For example, the definition describing biological agents as "bacterial, viruses, fungi, or parasites that cause human disease" does not encompass all biological agents addressed by the Policy, including "gene drive modified biological agent" and "RG1 wild-type biological agents." Because not all biological agents cause human disease, "human pathogenic agent" may be a more accurate term where the Policy specifically intends to refer to agents capable of causing human disease.

Definitions that Require Clarity: The definition of "toxin" is overbroad and, as written, does not accurately describe a toxin. Unlike other biological agents, toxins do not replicate and may be more appropriately considered analogous to chemical hazards. The definition should clarify the characteristics of toxins, such as toxicity (LD_{50} or LC_{50}) and if small molecule toxins are intended to be included. The definition of "laboratory research" should also be revised to encompass research activities and settings that may require biosafety oversight but do not neatly fit within a BSL/ABSL 1-4 designation. Examples include arthropod containment, clinical research activities, and research with plants expressing toxins that affect humans.

3. Broaden the reference framework for risk assessment and containment standards.

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

Limitations of Reliance on the Biosafety in Microbiological and Biomedical Laboratories (BMBL): The Draft Policy relies heavily on the BMBL for agent-specific containment requirements. However, the BMBL does not provide Risk Group classification for agents and lags behind emerging or rapidly evolving research. Institutions have historically relied on the NIH Guidelines for Recombinant and Synthetic Nucleic Acids, World Health Organization, the Public Health Agency of Canada, or other recognized national and international authorities to assist in determining the agent Risk Group. The Policy should provide the risk-based rationale for prescribed minimum biosafety levels and clarify how its requirements apply outside conventional benchtop laboratories, including clinical, animal, large-scale, and other research settings where appropriate containment may depend on site-specific engineering, administrative, and procedural controls.

National Risk Group Classification and Institutional Authority: NIH should maintain an authoritative, regularly updated Risk Group classification resource, similar to the agent classification framework included in earlier versions of the NIH Guidelines for Recombinant and Synthetic Nucleic Acids. NIH should establish a defined process and frequency for reviewing and updating agent classifications and containment recommendations. NIH should establish nationally consistent Risk Group classifications, while institutions retain authority to determine appropriate biosafety level, containment requirements, and oversight based on local IBC risk assessments, available controls, and the specific research being conducted.

NIH should also clarify the relationship between Risk Group classification and Containment Levels. Risk Group classification generally describes the hazard associated with an agent or activity, while Containment Level describes the controls and containment measures appropriate for a particular operation. The final Policy or accompanying guidance should not treat these concepts as interchangeable. NIH may establish national minimum expectations or reference points, but the institutional IBC should retain the authority to assign or approve the appropriate containment level for a specific activity based on the institution’s risk assessment, available engineering and administrative controls, institutional risk acceptance, and applicable internal standards. Institutions should also be permitted to impose more stringent containment or oversight requirements when warranted by site-specific conditions.

NIH Review Process and Timelines: The Policy should clarify what constitutes an "initial request," when NIH approval is required, and whether determinations apply to individual experiments or more broadly to an agent or category of research. NIH determinations and their rationale should be publicly available and applicable across institutions when appropriate, reducing duplicative submissions and unnecessary delays. NIH should define what constitutes a "timely" review by establishing target turnaround times, completeness criteria, a process for additional information requests, and an expedited pathway for urgent public health research. NIH should provide decision trees, a searchable repository of prior determinations, and pre-authorized categories for well-characterized agents, attenuated strains, and replication-defective vectors to further reduce unnecessary case-by-case review.

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

UC supports the proposed streamlined process under which an NIH-approved containment reduction is publicly posted and may subsequently be relied upon by other IBCs without separate NIH approval. NIH should clarify whether each determination applies to a particular agent, strain, construct, or activity; the information institutions must retain; the circumstances requiring renewed review; and the extent to which IBCs may impose more stringent controls based on site-specific conditions.

4. **Preserve Institutional Biosafety Committee (IBC) authority and institutional-based risk assessment.**

IBC as Primary Oversight Body: The proposed Policy should preserve the longstanding role of Institutional Biosafety Committees as the primary bodies responsible for conducting research-specific risk assessments and determining appropriate containment. Multiple provisions appear to shift decision-making authority from the institutions to NIH while simultaneously emphasizing risk-based oversight. Consistent with the Policy's focus on human health, IBC expertise requirements should be strengthened to include expertise in biosafety, public health, and infectious diseases. Animal research expertise should be included, as applicable, without specifying the animal model type, to allow institutions to evaluate the relevant expertise needed. The Policy should retain the requirement for a BSO for large-scale biological research.

Full Review versus Delegated Review Requirements: The Policy should clearly distinguish activities that require full IBC review from those eligible for delegated review. Requiring review of all genetically modified cells, viruses, or organisms could create substantial burden for routine low-risk research. This is particularly relevant for genetically modified arthropods and animals. The apparent inconsistency between delegated review for transgenic organisms at BSL-1/ABSL-1 and the BSL-2 minimum containment requirement for GDMOs should be resolved. NIH should provide a tiered decision framework, with examples of activities that may be handled through full IBC review, delegated review, or exemption. The framework should identify escalation triggers, while preserving institutional authority to impose additional review based on site-specific circumstances.

Expand Delegated Review Criteria: The defined delegated review criteria may be too narrow given the expanded scope, producing net added burden for low-risk work. These criteria should be expanded for routine low-risk research such as replication-incompetent or non-integrating vectors, reporter-only constructs, cell lines, primary materials, transgenic animals, low-risk genetically modified organisms, with clear criteria for when elevation to full IBC review is required. A full committee review of these research materials would be overly burdensome and would fall more in line with the delegated IBC review tasks based on risk.

Exemptions from the Policy: NIH should clearly explain how exemptions are intended to operate under the new Policy, including whether existing institutional practices may continue, whether exempt determinations require IBC review or documentation, and what circumstances

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

require escalation to delegated or full IBC review. NIH should address transition expectations for exempt research activities that may not have been historically reviewed by the IBC.

NIH should distinguish between activities that are outside the scope of the Policy, activities that are exempt from formal IBC review but remain subject to institutional documentation or oversight, and activities eligible for delegated review. This distinction should be reflected in the Policy's definitions, decision tools, and implementation guidance.

Occupational Health and Safety Plan Clarification: Additional clarification is needed regarding the Occupational Health and Safety Plan (OHSP), including when such plan is required, the elements NIH expects institutions to maintain, and the scope of NIH oversight or authority in this area.

5. **Revise public disclosure requirements for Institutional Assurances, meeting minutes and incident reports that balance transparency with privacy, biosecurity and reporting integrity.**

Redaction and Security Standards: Public posting of IBC meeting minutes, incident reports, and Institutional Assurances without uniform standards for disclosure and redaction may create security, privacy, proprietary, and reputational risks and could discourage timely and complete reporting. The Policy states that "appropriate and allowable redactions" can be made. To promote consistency across institutions, NIH should establish and publish a standardized redaction framework that clearly identifies information that should be withheld, including sensitive facility or inventory information, security vulnerabilities, proprietary methods, titles, and personal identifiers. Public disclosure requirements should account for incidents involving ongoing investigations, litigation, privacy restrictions, or oversight by another federal or state agency. For BSL-3, BSL-4, GDMO, "other pertinent information," or other potentially security-sensitive research, NIH should not require public disclosure of information that could compromise broader federal biosecurity objectives, reveal protected intellectual property or proprietary information, or create material financial, competitive, privacy, or security harms. The Policy should clearly define the minimum information that must be publicly available and establish consistent standards for withholding or redacting protected information.

Incident Reporting Thresholds and Timeline: NIH should replace institution-by-institution public posting of all incident reports with a two-tier reporting framework. NIH-reportable and high-consequence incidents should be reported to NIH and summarized publicly using standardized redactions. Lower-risk incidents, near misses, and anomalies should be maintained through institutional systems and aggregated in a centralized, de-identified database. Further, NIH should establish clear reporting thresholds that distinguish events involving a credible exposure or release pathway from contained anomalies in which redundant controls remained effective. The Policy should clarify the relationship among incident reports, IBC meeting minutes, and Institutional Assurances, including how confidentiality, retention, and disclosure requirements apply when an incident involves multiple protocols or grant funding periods.

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

Additional time beyond the 24-hour requirement or alternative disclosure procedures should be available for security-sensitive incidents or those subject to active investigation.

Centralized Incident Database: Given NIH's proposal to establish a centralized capability to aggregate, de-identify, and analyze biosafety incidents, near misses, and anomalies, NIH should consider using this mechanism to provide a centralized, anonymized public database rather than requiring institutions to publish individual reports on their website. This approach could provide meaningful transparency and opportunities for shared learning while preserving the culture of trust necessary for robust internal incident and near-miss reporting.

Continuity Mechanism: The Policy should include a continuity mechanism, such as an extension while an Institutional Assurance renewal is under NIH review, to ensure that administrative processing delays do not unnecessarily interrupt otherwise compliant research.

6. **Clarify containment and oversight standards for gene drive modified organisms and address environmental, agricultural, animal and arthropod risks more comprehensively.**

Oversight of Genetically Modified Plants: NIH should clarify whether another federal agency will have oversight authority for genetically modified plants and provide justification for their exclusion from this Policy. Genetically modified plants may express toxins, have the potential to contaminate native plant varieties through pollen or seed flow, and may impact associated arthropod communities or soil microbiota.

Arthropod Oversight and Containment Levels: While gene drives in animals, including arthropods, require increased containment levels under this Policy, similar requirements for plants have been removed from IBC oversight. The Policy should clarify if gene drive modified organisms that do not impact human health are within the scope of this policy. The requirement for research with gene drive modified organisms to be conducted at a minimum of BSL-2 containment is a poor fit for genetically modified insects such as mosquitoes, flies, or other arthropods, as the biosafety level terminology primarily focuses on infectious-agent risk. For many gene-drive or genetically modified arthropods, the principal hazard is environmental escape and establishment, not infection of laboratory personnel. As such, the appropriate terminology would be arthropod containment levels (ACL). The Policy should distinguish between human health biocontainment and environmental containment of genetically modified organisms.

Environmental, Agricultural, and Animal Health Risk: More broadly, environmental risk and consideration is captured in multiple sections of the Policy, but only human health is noted in the scope of this Policy. The Policy should clarify if environmental, agricultural, and animal health risk should be considered under the scope of this Policy. Any environmental, agricultural, ecological, or animal-health risks included within the Policy should be governed by the separate threshold described in Section 1 and should not expand the Policy’s scope through open-ended interpretation of “biohazard”.

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

7. Reduce administrative burden and eliminate regulatory redundancy.

Extend Implementation Timeline: The implementation timeline should be extended from "6 months from publication of final Policy" to a minimum of 12 months to allow institutions sufficient time to develop and validate systems necessary to comply with the new Policy. NIH should clarify how the proposed institutional biosafety assurance is intended to complement existing compliance certifications associated with NIH funding to ensure the process avoids duplicative administrative requirements. Each assurance requirement should be revised to express each statement as a complete, clearly defined institutional responsibility or submission element. Model templates and electronic resources should be made available ahead of the Policy effective date, including risk assessment tools, delegated review templates, incident reporting template, redaction guidelines, and public meeting minute formats.

Records Retention: Records-retention requirements should be specific to IBC oversight rather than directly tied to award financial-record retention periods. IBC oversight is based on active institutional research and does not necessarily align with grant submission or financial-reporting cycles. Accordingly, the Policy should define the categories of records subject to the retention requirement and distinguish institutional IBC records from grant records. IBC protocols are often living documents that evolve with active research and institutional controls and may not correspond directly to the scope of an individual grant proposal.

IBC Submission Timeline: Requiring a *de novo* IBC registration submission every 3 years can present a significant administrative burden on both the Principal Investigator and the IBC. NIH should allow institutions to establish periodic review intervals based on the nature and the risk level of the research.

Meeting Minutes Documentation and Public Posting: Public-posting requirements should be limited to information necessary to promote meaningful transparency and accountability. The requirement to post approved minutes immediately following approval, or by the next convened meeting, should be modified to provide institutions reasonable flexibility based on meeting frequency and administrative capacity.

Meeting Minutes and Incident Report Templates: Mandatory NIH templates for meeting minutes and incident reports may be overly prescriptive for institutions with established electronic systems and may increase administrative burden without improving safety outcomes. NIH should consider permitting substantially equivalent formats, including exports from institutional electronic systems, provided all required data elements are captured. NIH should publish a machine-readable list of required fields to standardize content while minimizing duplicative work. Additionally, NIH should consider removing training information from the meeting minutes template. Personnel training records are dynamic in nature and may contain personnel-identifying information that institutions would otherwise need to redact prior to making records available to the public. Training documentation is more appropriately maintained through separate institutional tracking mechanisms.

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

Standardized IBC Training: NIH should create and publish standardized IBC member training to outline the roles and responsibilities of IBC membership and include information about the review process. This would ensure that local IBCs are analyzing and assessing research activities with consistency instead of relying on third party or institution-created training for their IBC members.

Coordination with Existing Federal Oversight: Additional clarification is needed regarding the relationship between this Policy and other existing federal oversight. Several areas appear to overlap with established requirements administered by Occupational Safety and Health Administration (OSHA), Federal Select Agent Program (FSAP), Food and Drug Administration (FDA), Animal and Plant Health Inspection Service (APHIS), and the recently issued July 2016 United States Government Policy for Stopping High-Risk Life Sciences Research. The Policy should clearly identify which agency has primary oversight responsibility when multiple regulatory requirements apply and explain how overlapping requirements will be coordinated to avoid duplication or conflicting determinations. NIH should define which specific requirements outlined in the Policy are applicable when research may fall under the purview of multiple agencies or federal policies.

8. **Establish a clear biosafety oversight framework for clinical research.**

IBC Role in Clinical Research: The Policy does not adequately define the IBC's role in overseeing clinical research. IBC oversight of clinical research should complement, rather than duplicate, other federally required review and applicable human-subject protections. Where FDA and other regulatory processes already address product safety, shedding, or related risks, the Policy should clearly define the specific biosafety issues that remain within IBC oversight and establish clear endpoints for that oversight, such as last administration of an investigational product and a defined, evidence-based shedding monitoring window. This gap can create duplicative oversight, administrative confusion, and unnecessary delays for clinical research programs. The clinical research provisions should be reconciled with the 21st Century Cures Act, the Common Rule under 45 CFR 46, and existing FDA oversight frameworks.

Clinical Definitions and Terminology: As noted in our definitional comments, the absence of definitions for "shedding," "replicating," "integrating," "higher risk manipulations," and "product" creates significant challenges for institutions to apply effective clinical biosafety oversight.

Hierarchy of Controls and Tiered Risk Management: The Policy's risk assessment considerations for clinical research should take a layered approach to safety and focus on the hierarchy of controls. While the Policy acknowledges that clinical laboratories do not use traditional biosafety levels, the only risk mitigation guidance provided for clinical personnel is the use of universal precautions. This significantly understates the appropriate approach to clinical biosafety. Standard precautions should serve as the established baseline, with transmission-based precautions implemented based on the hazard characteristics and routes of

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

transmission specific to the investigational product or procedure. The Policy should reflect a tiered model of risk management.

9. Provide guidance for synthetic biology and artificial-intelligence assisted research.

Emerging Technology Oversight Gap: The rapid advancement of synthetic biology and artificial intelligence-assisted research design represents a growing category of biosafety concern that the Policy does not address. Both technologies have the capacity to substantially accelerate research workflows, lower barriers to the design and synthesis of novel biological agents and produce outcomes that existing oversight frameworks were not designed to evaluate. NIH should provide implementation guidance and institutional review tools for these areas, either in the final Policy or in accompanying guidance.

Synthetic Biology: With respect to synthetic biology, the Policy should provide guidance on the oversight of research involving the *de novo* synthesis of genetic sequences, the creation of novel biological constructs without natural counterparts, and the application of standardized biological parts in ways that may confer new or enhanced properties on organisms or agents. NIH should provide criteria and examples identifying which categories of synthetic biology work require IBC review, delegated review, or no additional biosafety review.

Artificial Intelligence and Large Language Model-Assisted Biological Design: With respect to artificial intelligence (AI) and large language model-assisted biological design, the Policy should establish review triggers and minimum institutional safeguards applicable when AI tools are used to propose, optimize, or select biological designs tied to high-consequence properties, including enhanced transmissibility, expanded host range, immune evasion, antimicrobial resistance, environmental stability, or increased toxicity. These safeguards should be narrowly and precisely defined so as not to impede general computational research, bioinformatics, or routine AI-assisted data analysis, while ensuring that AI-facilitated pathways toward potentially dangerous agent characteristics are subject to appropriate institutional and federal oversight.

10. Required Guidance Documents and Implementation Resources

To support consistent implementation while preserving institutional flexibility, NIH should make the following guidance documents, templates, decision tools, and reference resources available before the effective date of the final Policy.

- Examples of research activities and determinations to assess if the work falls within the scope of the Policy
- Guidance confirming institutional IBC authority to assign or approve containment and oversight based on research-specific risk assessment, institutional risk acceptance, available controls, and internal standards
- Risk group classifications
- Template to request NIH determination for risk group assessment and biosafety level reduction

Docusign Envelope ID: 26C7346B-39E8-8EF7-81EA-02129A91D6B2

- Guidance on reliance upon posted NIH containment-reduction determinations, including the scope and applicability of each determination, criteria for when a new NIH request is required, and documentation and recordkeeping requirements for IBCs relying on a prior determination
- Searchable repository of prior NIH determinations on Risk Group classification and Biosafety Level or containment reduction
- Incident report template
- Incident reporting decision tree on what is required to be submitted to NIH and publicly posted
- Guidance on incident-reporting timelines, redactions, active investigations, and alternative disclosure procedures
- Machine-readable list of required fields for public meeting minutes
- Risk assessment template with references beyond the BMBL
- Guidance on environmental, agricultural, ecological, animal-health, and arthropod risks
- Decision tree distinguishing activities outside the scope of the Policy, activities exempt from formal IBC review but subject to institutional documentation or oversight, activities eligible for delegated review, and activities requiring full IBC review.
- Delegated review template
- Standardized redaction reference
- Standardized IBC member training
- Occupational health and safety plan template
- AI and LLM research examples with determinations if they are within the scope of Policy
- Synthetic biology risk assessment template

Thank you for the opportunity to comment. We look forward to continued engagement on this important Policy.

Sincerely,

272. Battelle Memorial Institute

I am responding: On behalf of an organization

Name:

Name of Organization: Battelle Memorial Institute

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: PURPOSE
Because the NIH is extending their policy to vast swathes of non-NIH funded biological science research, development, testing and evaluation funded by the U.S. Government, the NIH should also commensurately reflect the broader U.S. Government biological science drivers in their purpose statement. Hence, we recommend that the NIH include the following sentence in their purpose statement. The first paragraph under the Purpose heading is recommended to be modified as follows: "As the world's largest public funder of biomedical research, NIH is committed to ensuring that gold-standard science is conducted under gold-standard biosafety conditions…"

Insert: The NIH is also committed to preserving and advancing the United States' research and development advantage on the global stage by strengthening both basic and applied biological science process and practice guidance, while maintaining a robust biosecurity and biological defense posture.

"…The purpose of the NIH Biosafety Policy for Research Involving Biohazards (the Policy) is to achieve this goal by setting forth requirements for federal and local institutional oversight of biomedical research involving biohazards, and to help ensure the safe, responsible, effective, and secure conduct of such research." We recommend that the NIH also leverage the National Biosafety Data and Safety Analysis Center (NBDSAC) function to reduce the new policy-imposed vulnerabilities that the draft NIH Biosafety Policy generates, if implemented as written.

The NIH is also inadvertently opening a large security gap with this draft language. The draft policy generates a new personally identifying information (PII) vulnerability by linking discoverable personal names with biological science, and more seriously biological defense, scope. It is strongly recommended that the NIH consult with senior U.S. Federal law enforcement stake holders to more fully assess the policy-imposed vulnerabilities that would be generated if this guidance document is implemented as written.

NON-NIH FUNDED RESEARCH

The draft would apply to covered non-NIH-funded research conducted at an institution receiving NIH funding. This would extend NIH requirements to research sponsored by other federal agencies and private entities, including work that may be subject to sponsor confidentiality, proprietary-information, security, or contractual restrictions.
• Many CRO client studies involve proprietary projects of short duration protected by confidentiality agreements.
• Requiring public disclosure of this work can violate client contracts and jeopardize intellectual property (IP).

Mandatory public disclosure imposes unnecessary burdens and discourages sponsors from using US-based CROs, weakening the US biological science enterprise.

The NIH wisely added wording at the end of Section II. Scope stating that "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." We recommend adding clarity to Section III-B. IBC Functions so that the second sub-bullet under the first main bullet reads: "When possible and consistent with protection of privacy, proprietary interests, and national security concerns…
INSERT: and within the constraints of other federal agency oversight referenced in Section II. Scope,"

• NIH should limit mandatory applicability to NIH-supported research and encourage voluntary adoption for other research from other funding sources.
• If NIH retains institution-wide applicability, NIH should create a defined process for work subject to other federal oversight or sponsor-imposed disclosure restrictions and clarify how such work can comply without public release of restricted information. This process should explicitly safeguard client identities, proprietary methods, Controlled Unclassified Information (CUI), and IP so that CROs can maintain a diverse client base without jeopardizing business relationships or breaching contractual obligations.

OTHER FEDERAL OVERSIGHT AND REQUIRED CLEARANCES
The provision allowing research to proceed under another federal agency's oversight is not sufficiently specific. The draft does not identify which agencies or programs qualify, what approvals or clearances are required, or which NIH requirements continue to apply.
• NIH should identify qualifying agencies and programs, including the Federal Select Agent Program where applicable, and define the approvals or clearances required.
• NIH should clarify which agency has priority for compliance determinations and how duplicative or conflicting requirements will be resolved, particularly where Federal Select Agent Program (FSAP) security and inventory rules already govern the work and public disclosure would conflict with those rules. We recommend that the FSAP rules have priority over NIH Biosafety Policy.
• NIH should clarify priority when multiple qualifying agencies are applicable.
• NIH should clarify what approvals or clearances are required to follow other agency oversight and how those are obtained.

REFER TO ATTACHMENT
In addition to these comments, please refer to the submitted attachment for a more detailed discussion

of the concerns and recommended actions for NIH consideration. For clarity, these associated concerns are as follows:

ITEM 1: PUBLIC DISCLOSURE of program details through the BIOSAFETY ASSURANCE
DRAFT REFERENCE: Section III-A (Assurance submissions: weblinks "to the maximum extent possible" to procedures, a continuously updated IBC roster, minutes, processes for how biosafety risks are managed, incident reports, training synopses; whether the institution conducts BSL-3/4 research).

CONCERN: The Assurance would direct the public to a consolidated profile of each institution, including where high-containment work is conducted. This information supports transparency, but it is equally useful to those who wish to target personnel, disrupt operations, or gain inside knowledge of how a program functions.

Procedures and incident reports are written for a technical audience and do include the context needed to understand them. However, the general public is unlikely to have the specialized biosafety knowledge to interpret that context accurately, so these documents are likely to be misread or misinterpreted. Continuous updating and long retention increase both risks. The draft policy contains no express authority to withhold security-sensitive material from the public weblinks.

REQUESTED ACTION
• Remove the expectation that the Assurance submissions link to public postings of procedures, processes for how biosafety risks are managed, rosters, minutes, training synopses and incident reports.
• Allow institutions to provide this information to NIH confidentially, with public disclosure limited to a high-level institutional attestation of compliance.
• Do not require public identification of BSL-3/4 or GDMO capability at the institution level.
• State expressly that institutions may withhold security-sensitive information, and require that NIH protect submitted Assurances from public release to the extent permitted by law.
• Allow institutions to submit the same information already submitted to other federal regulatory programs (e.g., the Federal Select Agent Program) rather than creating duplicate or conflicting information.

ITEM 3: “INCIDENT” AND “SIGNIFICANT RISK TO HUMAN HEALTH” ARE UNDEFINED, AND “ANY INCIDENT” AT BSL-3/ABSL-3 AND BSL-4/ABSL-4 IS OPEN-ENDED
DRAFT REFERENCE: Section III-B, IBC Functions (reportable incidents "pose a significant risk to human health"; "any incident" at BSL-3/ABSL-3 or BSL-4/ABSL-4; 24-hour notification to NIH)

CONCERN: Section III-B states that reportable incidents are those that "pose a significant risk to human health." The draft policy defines neither "incident" nor "significant risk to human health," and it gives no objective test for either. The list then covers "any incident" at BSL-3/ABSL-3 and BSL-4/ABSL-4. The list is introduced with "including," but "any" combined with an undefined term can reasonably be read to capture every event at those levels, regardless of risk. The word "any" also contradicts the stated "significant risk" threshold. The likely results are subjective and inconsistent determinations across institutions, over-reporting, and a 24-hour clock applied to events that do not pose a significant risk to human health.

REQUESTED ACTION
• Define "incident" in the draft policy with objective criteria.
• Define "significant risk to human health" and use it as the single threshold for every reportable category.
• Replace "any incident" at BSL-3/ABSL-3 and BSL-4/ABSL-4 with a closed, enumerated list of reportable event types. Examples are confirmed or potential laboratory-acquired infection, overt exposure (as defined by NIH), and loss of containment with potential for exposure.
• Provide decision criteria and examples for events below the threshold. State that these are documented and handled internally under IBC oversight rather than reported to NIH or publicly posted.

ITEM 4: “BIOLOGICAL AGENT INVENTORY...”
DRAFT REFERENCE: Section III-B, IBC Functions (BSL-3/ABSL-3 and BSL-4/ABSL-4 incident list)

CONCERN: The phrase "may have public health consequences" is speculative and has no objective test, because almost any inventory or security event could arguably meet it. Inventory and security events involving select agents and toxins are already governed by the Federal Select Agent Program (42 CFR Part 73; 7 CFR Part 331; 9 CFR Part 121). A parallel 24-hour NIH report, followed by public posting, duplicates that oversight. It also publicizes security information that is normally protected and could be exploited by malicious actors.

REQUESTED ACTION:
• Exclude agents regulated under the Federal Select Agent Program from this category, and defer to that program and other applicable security regimes.
• If any version is retained, replace "may have public health consequences" with an objective standard.
• State explicitly that inventory, security and access-control information is excluded from any public posting.

ITEM 7: APPLICATION OF THE DRAFT POLICY TO NON-NIH FUNDED RESEARCH AT ANY INSTITUTION RECEIVING ANY FUNDING
DRAFT REFERENCE: Section II, Scope ("This Policy is also applicable to non-NIH funded research that is conducted on or after [effective date] at an institution that receives any NIH funding"; the Scope also applies "regardless of NIH funding level or funding mechanism"); Compliance and Enforcement (institutions "shall ensure that any research conducted at or sponsored by the institution, irrespective of the source of funding, shall comply with this Policy"); General Definitions, "Biomedical research" (includes "non-NIH funded research that is conducted at an institution that receives any NIH funding"); Section III-A (no research subject to the draft policy may be conducted until NIH approves the institution's Biosafety Assurance)

CONCERN:
• Overreach. The draft policy already defines "NIH-supported research" as all research funded in whole or in part by NIH. It then extends the draft policy to every other research program at the institution. A single NIH award of any size, through any mechanism, would pull in the institution's entire portfolio,

including work funded by other federal agencies and private clients. Institutions that draw funding from many sources are affected most and are disproportionately impacted. The connection between receipt of NIH funding for one project and regulation of unrelated research activities elsewhere within the institution is not clearly articulated.

• Contractors, collaborators and shared facilities. The draft policy also, as written, does not address how obligations apply to contractors, subcontractors, collaborators, partnerships, or shared facilities. There may be conflicting oversight obligations when only some participating organizations receive NIH funding.

• Existing oversight. Much of this work is already overseen by its own sponsors and regulators, especially at the federal level. These sponsors often require comparable biosafety documentation, reviews and incident reporting. Applying NIH requirements on top creates duplicate review and reporting, and it can produce conflicting findings and timelines. The deference language in Section II refers only to "another federal agency," does not define the "approvals or other applicable clearances" required, and does not address private sponsors.

• Financial burden. Institutions would have to submit and maintain an Assurance, put additional protocols through IBC review, complete incident reports, and publicly post information for programs that NIH does not fund. The notice materials do not include a cost estimate for this expansion, and the costs would fall on institutions and, through them, on non-NIH sponsors. Low-risk non-NIH-funded projects may become subject to the same administrative burdens as activities that present substantially greater biosafety risk.

• Delay. The draft policy bars all covered research until NIH approves the Assurance, and it sets no review deadline for NIH. Because the draft policy reaches non-NIH work, an NIH delay could stall sponsor programs that have fixed contract schedules and deliverables, even though NIH is not funding or directing the work.

• Sponsor restrictions. Public posting and disclosure requirements can conflict with confidentiality, proprietary-information, controlled unclassified information, export-control and security terms in sponsor agreements. An institution cannot unilaterally breach those terms, and the draft policy provides no mechanism to reconcile them.

• Classified work. The draft policy does not address government-classified research. Classified programs cannot be disclosed in an Assurance, in IBC minutes or incident reports, or on a public website. The existence of such work may itself be restricted. The draft policy's redaction language covers information that would "directly compromise institutional or national security," but only for the public posting of reports. It does not address the Assurance, IBC review, NIH reporting, or the personnel and clearances needed to review such material. Without accommodation, institutions with classified programs cannot show compliance without violating their security obligations.

• Enforcement exposure on non-NIH work under undefined standards. The draft policy states that failure to comply "may provide a basis for enforcement actions, including, but not limited to, additional special terms and conditions, or termination," and that enforcement "may affect future funding decisions for the recipient institution." Because the draft policy extends to non-NIH-funded work, an institution's NIH funding could be put at risk over research that NIH does not fund. The standards against which compliance would be judged are not yet defined. Examples include what "pose[s] a significant risk to human health"; what counts as an "incident" or as "any compliance violations"; what "a timely manner" means (the same draft policy that leaves NIH's response time undefined); what "other pertinent information" must be provided; and what redactions are "appropriate and allowable." Institutions cannot reliably demonstrate compliance with terms they must interpret on their own, and two

institutions could reach different, equally reasonable readings. The phrase "including, but not limited to" also leaves the range of possible enforcement actions open. Enforcement consequences this significant should rest on requirements that are clear, objective and known in advance.
• Competitive impact. The draft policy could create an uneven competitive landscape. Institutions that receive NIH funding would incur additional oversight, reporting, Assurance, and public disclosure obligations across their research portfolio, while institutions conducting comparable non-NIH-funded work without NIH funding would not. This may discourage participation in NIH-funded research and create incentives to separate research activities among affiliated entities.
• Commercial sponsor impact. Commercial sponsors may be unwilling to place proprietary research at institutions subject to mandatory public posting or NIH oversight on non-NIH-funded work. This could reduce research opportunities and increase costs for institutions and sponsors.

REQUESTED ACTION:
• Limit the draft policy to NIH-supported research as the draft policy already defines it. Delete the non-NIH-funded sentence in Section II, the "irrespective of the source of funding" language in Compliance and Enforcement, and the non-NIH clause in the "Biomedical research" definition.
• Continue to encourage voluntary adoption for other research, as the Voluntary Compliance section already provides.
• If NIH retains institution-wide application, require that it apply at the project or facility level, not through one institution-wide gate. Exempt research already overseen by another federal agency or by sponsor-required biosafety oversight from NIH review, incident reporting and public posting, and accept the other oversight body's documentation as meeting NIH's requirement.
• If NIH retains institution-wide application, exempt non-NIH-funded projects already underway before the effective date.
• Add an express provision for classified research. It should state that classified work is overseen under applicable national security requirements. It should also say that nothing in the draft policy requires disclosure of classified information, including the existence of the work, in an Assurance, in IBC records, or in any report to NIH or the public. Provide a compliance pathway that does not depend on disclosure.
• Provide an exemption or a defined process for sponsor-restricted work (proprietary, controlled unclassified, export-controlled or contractually confidential), with no public posting.
• Clarify whether the draft policy applies to contractors, subcontractors, and shared facilities.
• Do not gate research that NIH does not fund on NIH approval of the Assurance. If any non-NIH work stays in scope, set fixed NIH review deadlines and allow work to continue under existing sponsor and IBC oversight while review is pending.
• Publish a cost and burden analysis specifically for the expansion to non-NIH-funded research.
• Define the terms listed above in the draft policy before any enforcement authority applies, and tie each enforcement action to a specific, enumerated requirement.
• Limit enforcement actions affecting NIH funding to NIH-supported research. Do not link NIH funding decisions to compliance on non-NIH-funded work.
• Establish a graduated, documented enforcement process: written notice of the specific requirement allegedly not met, a reasonable opportunity to respond and correct, and an appeal path before any special terms, termination or funding consequence.
• Provide a good-faith compliance provision. Institutions that make a reasonable, documented interpretation of an undefined term would not face enforcement while NIH is still issuing

implementation guidance.
• Replace "including, but not limited to" with a defined list of possible enforcement actions.

ITEM 8: REPORTING OF “POTENTIAL RELEASES” FROM FACILITY OR EQUIPMENT FAILURES “EVEN WHEN REDUNDANT SYSTEMS WERE FUNCTIONING PROPERLY”
DRAFT REFERENCE: Section III-B, IBC Functions (reportable incidents at BSL-3/ABSL-3 or BSL-4/ABSL-4: "potential releases involving facility and/or equipment failures, even when redundant systems were functioning properly, to address the possibility of risk to personnel and the community and prevent future occurrences"); Section III-C (voluntary, confidential near-miss reporting to the National Biosafety Data and Safety Analysis Center)

CONCERN:
• Circular trigger. Redundant systems exist to prevent releases. When they function properly, no release occurs. The clause nevertheless requires a report of a "potential release," so the trigger depends on something that did not happen. The draft policy does not define "potential release," so institutions cannot tell what counts. Requiring a report when backup systems perform exactly as designed treats successful risk mitigation as evidence of a reportable incident rather than a demonstration that the
• containment system functioned properly. In addition, public reporting of events in which containment was never lost may create the appearance of a biosafety failure where none occurred.
• Inconsistent with the "significant risk" threshold. Section III-B limits reportable incidents to those that "pose a significant risk to human health." A failure that a redundant system contained does not meet that threshold, and the draft policy does not reconcile the two.
• Undefined scope. "Facility and/or equipment failures" has no limits. Without a definition, a wide range of routine faults and maintenance events could become reportable. That would drive over-reporting, inconsistent determinations across institutions, and a heavy burden of review, reporting and public posting. A high volume of low-risk reports could divert attention from events involving actual exposures, releases, or containment failures.
• Disincentive to good design and candid reporting. Treating a successful backup as a reportable event discourages institutions from recording and discussing equipment faults openly. That works against NIH's stated aim of learning from near-misses.
• Inconsistent with the voluntary near-miss framework. The draft encourages voluntary, confidential reporting of near-misses and secondary failures to the National Biosafety Data and Safety Analysis Center, and it says NIH will not use that data for enforcement unless there was an environmental release or lab acquired infection. This clause requires essentially the same kind of event to be reported to NIH, and posted publicly, under the mandatory process.
• Overlap with existing oversight. Facility and equipment performance is already governed by existing biosafety, facility-maintenance and, where applicable, Federal Select Agent Program requirements. The draft does not say how this reporting relates to them.

REQUESTED ACTION:
• Delete "even when redundant systems were functioning properly." Events in which secondary or redundant controls performed as designed should not be reportable to NIH.
• Limit this category to equipment or facility failures that result in a loss of containment, an actual

release, or an exposure, or that create a documented potential for exposure that safeguards did not prevent. Define "potential release" with objective criteria.
• Handle failures in which redundant systems held as internal events, reviewed by the IBC and documented locally, as the draft already does for lower-risk incidents that "must be reported to and addressed by the IBC" but not NIH.
• Direct near-miss and secondary-failure information to the voluntary, confidential framework in Section III-C, with the protections stated there. Do not make it a mandatory, publicly posted report.
Define "facility and/or equipment failure" using objective, risk-based criteria such as loss of primary containment, loss of negative pressure beyond established limits, failure of decontamination systems, or failure resulting in actual exposure or release. Align any retained reporting with existing federal requirements, so one event does not trigger parallel reports.

ITEM 9: RECORDS RETENTION AND DURATION OF PUBLIC AVAILABILITY
DRAFT REFERENCE: Section III-A (records retention "in accordance with Section 8.4.2 of the NIH GPS … 2 CFR 200.334," and "IBC meeting minutes and incident reports must be publicly posted for a minimum of five years"; incident reports and minutes containing award-related records "must be made available to the public during this time if requested")

CONCERN:
• The draft policy ties records retention to the federal baseline of three years under 2 CFR 200.334 and NIH GPS 8.4.2, then sets a separate five-year public posting requirement. The two are different obligations, and the draft policy gives no safety rationale for the longer public period.
• 2 CFR 200.334 provides that Federal agencies "may not impose any other record retention requirements" except for specified circumstances. The draft policy does not identify which exception supports a five-year requirement.
• The draft policy does not say when the five years begin (posting date, meeting or incident date, or award closeout). Incident reports can span multiple protocols at different stages of the grant cycle, so institutions cannot determine when posting may end.
• The draft policy uses both "publicly posted" and "made available to the public … if requested." It does not say which applies to which records, or what happens when a record is only partly award-related.
• A longer public window increases the aggregation and security risks as well as hosting, review and redaction costs. It also prolongs the risk of misinterpretation by non-expert audiences. NIH already has access to retained records for as long as they are kept, so extended public posting is not needed for NIH oversight.
• For research that NIH does not fund, no federal award exists, so the retention baseline does not apply, yet the five-year public requirement would.
• The draft policy does not address whether corrected reports, amended findings, or updated corrective actions replace prior versions, nor does it explain which versions remain publicly available. Retaining outdated information for extended periods could create inaccurate public record, especially as biosafety practices and facility capabilities change over time.

REQUESTED ACTION:
• Align any public availability period with the existing three-year baseline, or remove the fixed minimum, and keep records for NIH access under existing retention rules.

• If NIH retains a longer public period, state the safety rationale and the legal basis, including which provision of 2 CFR 200.334 permits it.
• Define when the period starts and ends, and how it applies to records spanning multiple protocols or awards.
• Clarify which records must be continuously posted and which need only be provided on request, and permit removal after the period ends.
• Clarify when and how records are updated throughout the reporting process.
• Exempt non-NIH-funded research from the public availability requirement.

ITEM 10: DEFINITION OF “BIOMEDICAL RESEARCH” AS RESEARCH “WITHIN THE MISSION OF THE NIH
DRAFT REFERENCE: General Definitions, "Biomedical research" ("Research on a topic that is within the mission of the NIH," including non-NIH-funded research conducted at an institution that receives NIH funding); Section II, Scope. The draft policy repeatedly conditions applicability on "research," but does not provide a general definition of "research" itself, and the separate definition of "laboratory research" addresses only where the work occurs.

CONCERN: For institutions that conduct multidisciplinary research, these provisions create uncertainty regarding independently sponsored defense, commercial, veterinary, environmental, product-development, validation, quality-control, surveillance, and similar activities. Applicability also turns on "known or potential risk to human health," which the draft policy does not define, so it is unclear how these activities are treated where human health is not the focus of the work.

Because coverage determines whether an Assurance, IBC review, incident reporting and public posting apply, and because enforcement can affect NIH funding, institutions need to know in advance which activities are covered. The same definition is also the basis for extending the draft policy to non-NIH-funded research.

REQUESTED ACTION
• Provide objective criteria and representative examples for determining when independently sponsored work is sufficiently within the NIH mission to constitute covered biomedical research.
• Define "research" for policy applicability and distinguish it from operational testing, validation, quality control, manufacturing support, diagnostics, training, and other related biological activities.
• Establish a formal process for institutions to request written applicability or scope determinations for ambiguous projects and activities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): ADMINISTRATIVE AND RESOURCE BURDEN
The expanded scope and review responsibilities would require additional biosafety personnel, compliance support, and information-technology infrastructure. The draft does not provide sufficient detail for institutions to estimate or plan for these responsibilities. CROs face higher relative impact because they manage large numbers of short-duration client studies rather than long academic grants (each new or amended protocol still triggers a review process and client-driven changes frequently occur).
• NIH should provide clear implementation expectations, supporting tools, and a phased transition that accounts for institutional staffing and system needs.

• NIH should establish proportionate review and documentation pathways so that research eligible for delegated review is not subject to the same risk-assessment narratives, meeting-minute detail, renewal requirements, and administrative documentation as research requiring full IBC review. An abbreviated record should document the research category, principal hazards, containment, material safeguards, reviewer determination, and approval conditions, while detailed risk-assessment and deliberative records should be reserved for higher-risk or uncertain research requiring convened IBC review.
• NIH, similarly, should provide a pathway for repetitive research and expedited approvals as described in the bullet above.

INFORMATION REQUIRED FOR NIH DETERMINATIONS
The draft uses open-ended language such as 'other pertinent information' in connection with institutional Assurances and petitions to NIH. This prevents institutions and committees from knowing in advance what information NIH will require.
• NIH should publish complete submission elements and objective review criteria for Biosafety Assurances and containment-determination requests.
• NIH should clearly define the limited circumstances in which additional information may be requested.

In addition to these comments, please refer to the submitted attachment for a more detailed discussion of the concerns and recommended actions for NIH consideration. For clarity, these associated concerns are as follows:

ITEM 11: RELIANCE ON OTHER FEDERAL OVERSIGHT, INCLUDING THE FEDERAL SELECT AGENT PROGRAM
DRAFT REFERENCE: Section II, Scope states, "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." Section V-A separately recognizes that the Federal Select Agent Program oversees the possession, use, and transfer of Select Agents and Toxins and states, "All entities must follow the requirements laid out in the Select Agent Regulations."

CONCERN: Although Section V-A names the Federal Select Agent Program, the draft policy does not say whether it is a qualifying program under Section II, what approvals or clearances are required, whether other federal oversight replaces or supplements NIH requirements, or which NIH requirements continue to apply.

REQUESTED ACTION:
• Identify qualifying agencies and programs, including the Federal Select Agent Program, and define the approvals or clearances required.
• Establish a formal reliance or equivalency framework that identifies which NIH requirements are satisfied by another federal oversight program and how duplicative or conflicting requirements will be resolved.
• State whether work under another federal agency's oversight remains subject to NIH incident reporting, public posting and IBC review.

ITEM 12: THREE-YEAR DE NOVO APPROVAL REQUIREMENT
DRAFT REFERENCE: Section III-B (IBC Functions) requires the IBC to periodically review approved research and states that approval may not exceed three years, at which time a de novo registration submission and review is required. Changes that may affect the original biosafety assessment must be reviewed before implementation.

CONCERN: The draft policy does not define the frequency, scope, or documentation for periodic review. Requiring a complete de novo submission every three years for unchanged, compliant, lower-risk research may divert resources from higher-risk oversight without a corresponding improvement in risk control.

REQUESTED ACTION:
• Define periodic-review expectations based on risk, compliance history, complexity, and whether material changes have occurred.
• Permit streamlined renewal or administrative continuation for unchanged, compliant research and reserve full de novo review for material changes, elevated-risk work, significant incidents, or compliance concerns.

ITEM 24: CLARIFY THAT BSO RESPONSIBILITIES MAY BE FULFILLED THROUGH OVERSIGHT OF QUALIFIED INSTITUTIONAL PROGRAMS AND PERSONNEL
DRAFT REFERENCE: Section III-B, Biosafety Officer (BSO) Requirements and Duties

CONCERN: Section III-B is written as a single BSO personally responsible for conducting inspections, investigating incidents, and performing other operational functions. The draft policy does not recognize that these activities are often carried out by a multidisciplinary team or institutional program operating under the direct oversight of the BSO.
Requested action:
• Clarify that the BSO is responsible for the oversight, coordination, and effectiveness of these functions and that inspections, investigations, assessments, and related activities may be conducted by appropriately qualified personnel operating under the BSO's authority.
• Include the following language: "The BSO's duties may be carried out directly by the BSO or through the oversight, coordination, and review of appropriately qualified institutional personnel operating under the authority of the BSO."

3. Continued utility of Risk Groups: The draft relies on Risk Groups but omits the agent classification lists contained in the current NIH framework. Institutions need an accessible and stable classification resource to support consistent risk assessment and review.
• NIH should continue to provide the Risk Group classification system as part of the policy or a clearly controlled implementation resource.
• NIH should explain how updates to Risk Group classifications will be communicated and controlled so institutions can apply them consistently.

In addition to these comments, please refer to the submitted attachment for a more detailed discussion of the concerns and recommended actions for NIH consideration. For clarity, these associated concerns

are as follows:

ITEM 25: CLARIFY AUTHORITY AND RESPONSIBILITIES FOR BIOCONTAINMENT DETERMINATIONS
DRAFT REFERENCE: Section III-B, IBC Functions (independent risk assessment of required biocontainment levels and notification of the required biocontainment level); Section III-C, Responsibilities of the PI (initial risk assessment and selection of biocontainment levels).

CONCERN: The draft policy assigns containment-related risk assessment responsibilities to both the PI and the IBC but does not clearly identify who is responsible for proposing, evaluating, and approving the final biocontainment level. The requirement for both an initial PI risk assessment and an independent IBC risk assessment could be interpreted as requiring multiple independent evaluations of the same hazards without clarifying how disagreements should be resolved.

REQUESTED ACTION:
• Clarify that the PI is responsible for conducting the initial risk assessment and proposing the appropriate containment level and risk mitigation strategy.
• Clarify that the BSO may provide technical review and recommendations regarding containment, containment practices, and risk mitigation measures.
• Clarify that the IBC is responsible for reviewing the proposed containment level, considering the recommendations of the BSO and other subject matter experts as appropriate, and approving the final institutional biocontainment level.
• Specify how differing assessments among the PI, BSO, and IBC should be resolved and identify the institutional authority responsible for the final determination.

ITEM 30: PRESERVE INFLUENZA-SPECIFIC SAFEGUARDS AGAINST UNINTENDED GENOMIC REASSORTMENT
DRAFT REFERENCE: Section IV, experiments involving influenza viruses; current NIH Guidelines, Section III-D-7, Experiments Involving Influenza Viruses.

CONCERN: The draft policy assigns containment for influenza research according to the Risk Group of the virus contributing the majority of genomic segments and establishes enhanced containment for certain 1918 H1N1, human H2N2, and HPAI H5N1 experiments. However, it does not expressly require institutions to evaluate and control the risk of unintended genomic reassortment when different influenza strains are studied concurrently or sequentially in shared rooms, equipment, animal spaces, or supporting systems.

Influenza viruses possess segmented genomes, and concurrent exposure to different strains can create conditions for reassortment. Available federal guidance, such as the BMBL, does not comprehensively address temporal and spatial separation for concurrent or sequential recombinant or synthetic influenza research. USDA APHIS guidance addresses concurrent HPAIV and 1918 influenza studies, but NIH should establish a broader framework for identifying and mitigating unintended reassortment risks involving other consequential strain combinations. This gap illustrates why Risk Group classification alone cannot replace a protocol-specific assessment of the resulting agent, concurrent research activities, shared

spaces and equipment, and credible pathways for unintended reassortment.

REQUESTED ACTION:
• Retain explicit influenza-specific safeguards requiring IBC assessment of unintended genomic reassortment during recombinant, synthetic, reverse-genetics, and reassortant influenza research. The assessment should address concurrent and sequential work, temporal or spatial separation, shared rooms, equipment and animal spaces, validated decontamination between activities, and documented clearance before another influenza strain is introduced.
• Publish influenza-specific implementation guidance identifying the existing safeguards that will be retained, modified, relocated, or discontinued and establishing minimum controls for strain combinations capable of producing a more pathogenic, transmissible, or otherwise consequential reassortant.

ITEM 31: RETAIN A STABLE AND TRANSPARENT RISK GROUP CLASSIFICATION RESOURCE
DRAFT REFERENCE: Section IV, Categories of Oversight for Research Based on Risk; Section V, Risk Assessment and Mitigation for Research Involving Biohazards; NOT-OD-26-112 and the Draft Policy Table of Changes regarding Risk Group classifications as implementation resources.

CONCERN: The draft policy relies on Risk Groups to determine oversight pathways and inform risk assessment but does not retain the agent classification lists contained in the current NIH Guidelines. Moving these classifications to a separate implementation resource creates uncertainty regarding where the authoritative classifications will reside, how changes will be reviewed and communicated, and whether classifications could change without stakeholder notice.

Risk Groups provide an important starting point for biological risk assessment, but they do not independently determine the appropriate containment level for a specific protocol. Final BSL or ABSL determinations must also consider the characteristics of the resulting agent, genetic modifications, experimental procedures, routes of exposure, scale, aerosol potential, animal work, and available safeguards.

REQUESTED ACTION:
• Retain the Risk Group classification lists in the draft policy or in a formally controlled, publicly accessible implementation resource that identifies the authoritative classification, revision date, supporting rationale, and effective date of each material change.
• Establish a transparent process for modifying Risk Group classifications that includes scientific review, advance notice to affected institutions, publication of the basis for the change, and a reasonable implementation period.
• Clarify that Risk Group classification is a starting point for protocol-specific risk assessment and does not automatically determine the final BSL or ABSL, which should be approved by the IBC based on the agent, modifications, procedures, and other relevant risk factors.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The following are suggestions of mechanisms which may encourage voluntary compliance while simultaneously providing benefits to those institutions required

to enroll.

NIH could establish a public-facing voluntary-adoption registry identifying institutions that attest to implementation of specified policy elements. Registrants could reference this verifiable designation in proposals and institutional materials, provided the designation does not imply NIH certification of individual studies or overall institutional performance.

Allow voluntary registrants to have the same access to NIH resources and tech support. As part of NIH implementation, the NIH should provide free policy implementation toolkits (e.g., webinars, templates, checklists) and tech support to any registrant, voluntary or mandatory.

Allow institutions to demonstrate voluntary compliance through existing federal oversight programs that meet equivalent or more stringent requirements. NIH should recognize overlapping controls implemented by FSAP-registered entities and other federally overseen institutions rather than require a separate voluntary enrollment.

Encourage other federal agencies to recognize an NIH voluntary-adoption designation where it is relevant to the agency's own biosafety or research-assurance requirements.

Provide a low burden approach to registration. Allow registrants to adopt the policy in phases specific to their current capacity, and undergo a scheduled external surveillance onsite or remote audit. NIH could accept equivalent inspections, audits, permits, or accreditation findings from applicable oversight programs rather than require a duplicative NIH review. NIH should recognize equivalent requirements and findings from applicable federal programs, including FSAP, the CDC Import Permit Program, and USDA APHIS permit or regulatory oversight. Findings from USDA Animal Care inspections and AAALAC International accreditation may serve as supporting evidence for relevant animal care and use program elements but should not be treated as automatic substitutes for biosafety review.

Following the model of the OSHA Alliance Program, NIH should collaborate with qualified biosafety professional organizations, such as ABSA International, to develop implementation tools, training, technical assistance, and de-identified lessons learned from voluntary early adopters, while retaining responsibility for policy interpretation and oversight.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The following template comments apply independently of Battelle's recommendation to eliminate or substantially limit public posting. If NIH retains the templates for institutional records or confidential NIH oversight, their scope, content, reporting thresholds, and redaction provisions should be revised as described below.

PUBLIC POSTING OF INCIDENT REPORTS AND DETAILED IBC INFORMATION
Public posting of detailed incident reports and meeting minutes could disclose Principal Investigator identities, research agents, locations, exposure pathways, animal husbandry practices, internal processes, and corrective actions. These disclosures could affect operational security, employee privacy, proprietary research, sponsor confidentiality, and institutional reputation, particularly when lower-risk events are presented without context. For CROs, public identification of scientists and staff creates a doxxing risk, while disclosure of agents, methods, or client-related details can destroy confidentiality and

IP protections that sponsors require.
• NIH should use de-identified national summaries and trend reporting as the primary public-transparency mechanism rather than requiring public posting of individual institutional incident reports.
• If institution-level posting is retained, NIH should permit withholding or redaction of personnel, client, proprietary, security-sensitive, facility, location, inventory, and internal-process information.
• NIH should provide a mechanism for non-NIH funded clients to apply for exemption of public identification

REPORTING THRESHOLDS FOR INCIDENTS AND COMPLIANCE VIOLATIONS
Terms such as 'any incident' at BSL-3/ABSL-3 or BSL-4/ABSL-4 and 'any compliance violation' at any BSL/ABSL are too broad to apply consistently. The language could capture administrative deficiencies or equipment events in which redundant systems functioned and containment was maintained.
• NIH should define reportable incident categories using objective criteria tied to actual or credible potential exposure, loss of containment, laboratory-acquired infection, or material public-health consequence.
• NIH should distinguish safety-significant violations from administrative deficiencies and specify which violations require immediate reporting.

DUPLICATION WITH EXISTING REGULATORY REPORTING
The proposed reporting structure overlaps with reporting to the Federal Select Agent Program (FSAP) and other regulatory bodies. Parallel reporting can create inconsistent records and additional administrative burden without a corresponding biosafety benefit.

NIH should coordinate with existing regulatory agencies, such as FSAP, and accept equivalent reporting through established regulatory channels. NIH should not require public posting of security, inventory, or access-control information reported under another federal oversight program.

REDACTION STANDARDS AND POSTING BURDEN
The draft does not provide sufficiently clear redaction standards. Preparing incident reports and minutes for public release would require recurring biosafety, legal, security, communications, and information-technology review.
• NIH should issue presumptive redaction and withholding categories and allow institutions to apply broader redactions when needed to protect personnel, clients, proprietary information, and security.
• NIH should not require duplicative incident reporting when another federal agency is involved in the oversight of the research, specifically the Federal Select Agent Program.
• NIH should account for the administrative burden created by public posting and avoid duplicating information already maintained by regulatory agencies.
• If NIH retains any public-reporting requirement, NIH should maintain a centralized platform limited to de-identified summaries of incidents meeting defined federal reporting thresholds. The platform should not require institutions to publicly post individual incident reports, corrective-action details, personnel identities, or sensitive operational information.

In addition to these comments, please refer to the submitted attachment, including:

ITEM 2: PUBLIC POSTING OF INCIDENT REPORTS
DRAFT REFERENCE: Section III-B, IBC Functions ("Posting all incident reports on a public-facing webpage"); Section III-A (public availability for a minimum of five years); Draft Incident Reporting Template (Redaction and Posting)

CONCERN: The draft policy requires every incident report to be posted publicly, including lower-risk events that are not reportable to NIH. Reports must remain posted for at least five years. Incident reports and the corrective actions they describe necessarily show how an institution's operations, controls and response procedures work. That detail can give malicious actors inside information about sensitive operations. Incident reports are written for a technical audience and do include the context needed to understand them. However, the general public is unlikely to have the specialized biosafety knowledge to interpret that context accurately. A routine, well-managed event can therefore be misread or misinterpreted as a failure. That can create unwarranted concern and may discourage candid reporting of near-misses. The redaction standard is narrow (limited to proprietary or private information and information that would directly compromise institutional or national security), and each institution sets its own criteria.

Additionally, candid reporting of incidents and near-misses is essential to an effective biosafety program; requirements that publicly name the Principal Investigator and the institution may further suppress the reporting needed to identify trends, evaluate safeguards, and prevent recurrence.

REQUESTED ACTION
• Remove the requirement to publicly post individual incident reports and corrective actions.
• Achieve transparency instead through the NIH Annual Incident Summary Report (Section III-D) and de-identified, aggregate analysis, so the public sees trends without institution-level operational detail.
• If any posting is retained, limit it to NIH-reportable incidents that meet defined criteria. Use summary-level, delayed posting. Do not require corrective-action detail. Give institutions explicit authority to withhold security-sensitive information.

ITEM 13: INCIDENT TEMPLATE, “REDACTION AND POSTING OF INCIDENT REPORTS”
DRAFT REFERENCE: "Information that is widely available from other public sources such as institutional webpages, publications describing an investigator's research, or public grants databases (e.g., names of IBC members and PIs, biological agents used in research, including Select Agents, grant numbers) is not considered private or proprietary and may not be redacted from reports."

CONCERN: This provision does not appear to allow institutions to consider the context created by aggregation of otherwise publicly available information. Individual pieces of information may already be public, while combining those data within an incident report could provide substantially greater insight into research activities, biological agents, personnel, incidents, and institutional vulnerabilities.

The explicit inclusion of "biological agents used in research, including Select Agents" raises an especially important security concern.

REQUESTED ACTION:

• Permit institutions to consider the cumulative or aggregated security implications of information when determining whether redaction is appropriate, even when individual elements exist elsewhere in the public domain. Security review should consider the context of the complete incident report, rather than only whether each individual data element has previously been made public.
• Before finalizing the public-disclosure and redaction requirements, obtain review from appropriate federal partners responsible for preventing biological threats and weapons of mass destruction (WMD)-related misuse, including the aggregation of otherwise public information.

ITEM 14: INCIDENT TEMPLATE, PI IDENTIFICATION AND STAFF ID
DRAFT REFERENCE: "Incident reports should not include any personally identifiable identification of individuals involved in the incident (aside from the Principal Investigator's name)." The incident narrative subsequently instructs institutions: "Who was involved in the incident/violation, including others present at the incident location? Note - do not identify individuals by name. Provide only position titles..."

CONCERN: The template protects the identities of personnel involved in an incident but specifically excludes the PI from that protection. Because these reports are required to be publicly posted, naming the responsible PI could unintentionally associate an individual with an incident even when the PI was not present, directly involved, or responsible for the causal factors.

REQUESTED ACTION:
• Remove the requirement of the disclosure of PI names from any publicly posted incident report.
• If NIH oversight requires PI identification, allow institutions to provide the PI identity to NIH while using a role or position designation in the public version, unless identification serves a defined public-health purpose.

ITEM 15: INCIDENT TEMPLATE, REPORTING REQUIREMENTS NOT CALIBRATED TO INCIDENT SEVERITY
DRAFT REFERENCE: "All fields must be fully completed in every final report. If an element does not apply, indicate not applicable."
CONCERN: The template requires the same general level of completion regardless of whether an incident involves:
• A contained BSL-2 exposure with no injury
• A documentation lapse
• A failure of redundant equipment with no release
• A potential laboratory-acquired infection
• A community release
• A major BSL-3 or BSL-4 containment event
A uniform reporting structure does not reflect a meaningful tiered approach based on risk.

REQUESTED ACTION:
• Establish two levels of reporting: 1) Internal institutional record for nonreportable events, with optional de-identified submission to NBDSAC and 2) NIH report for events meeting defined NIH reporting thresholds, with enhanced fields incorporated only when warranted by the severity of the event.
• Assignment to an NIH reporting tier should determine the information provided confidentially to NIH and should not, by itself, require public posting.

ITEM 16: INCIDENT TEMPLATE, OTHER AGENCY REPORTING IS CAPTURED BUT COORDINATION IS NOT
DRAFT REFERENCE: "Has a report of this incident been made to other agencies? If so, indicate: CDC, USDA, FDA, EPA, OSHA."
CONCERN: The checkbox documents that another report occurred but does not address duplication, conflicting timelines, inconsistent definitions, or whether NIH will accept information already submitted to another federal agency. This creates the possibility of multiple reports containing similar information in different formats.
REQUESTED ACTION:
• Accept an equivalent report submitted to another federal oversight agency as satisfying NIH reporting requirements for overlapping elements and require only supplemental information that is uniquely necessary for NIH oversight.
• Coordinate definitions, timelines, and required data elements with other agencies to reduce duplicative oversight.

ITEM 17: MEETING MINUTES TEMPLATE, SHIFTS SUBSTANTIAL LOCAL DELIBERATION INTO A FEDERAL/PUBLIC RECORD
DRAFT REFERENCE: "Institutions must prepare IBC meeting minutes that ... document for NIH and the public that the IBC is fulfilling its biosafety review and oversight responsibilities." Points to consider: "In general, the minutes should offer sufficient detail to serve as a record of all major points of discussion and the committee's rationale for decisions." "Key points made in discussion, motions of the committee, and whether those motions were approved should be documented."
CONCERN: Meeting minutes traditionally document committee action, but this template may transform detailed local technical deliberations into publicly available records used by NIH to judge compliance. Effective local oversight depends on committee members being able to discuss uncertainty openly without concern that preliminary statements will be interpreted externally as final findings.
REQUESTED ACTION:
• Require minutes to document the final risk assessment approval, committee decision, and approval conditions.
• A public-facing summary should state the general category of review, confirm that the required assessment occurred, and document the committee’s final action without disclosing sensitive technical or operational details. Do not require a detailed public account of every technical discussion, preliminary concern, or alternative considered.

ITEM 18: MEETING MINUTES TEMPLATE, MAY UNINTENTIONALLY INCLUDE GENERAL SAFETY MATTERS UNRELATED TO COVERED BIOHAZARDS
DRAFT REFERENCE: "All official business conducted at the IBC meeting should be documented using this template." Examples provided: "review of incidents, laboratory inspection reports, reports from safety personnel related to the safe conduct of research at the institution, personnel training, review of policies, etc."
CONCERN: These examples could encompass a broad range of institutional safety matters that are not necessarily connected to research involving biohazards covered by the draft policy. Laboratory inspections, training discussions, and reports from safety personnel frequently address chemical,

physical, radiological, ergonomic, animal-handling, and general occupational hazards. Requiring these discussions to appear in the public IBC record could extend the effective scope of the template beyond biosafety oversight.
REQUESTED ACTION:
• Specify that only the portions of inspection reports, safety discussions, training matters, or policy reviews that materially relate to research subject to the draft policy must be included in the required minutes, and that other institutional safety business remains within the institution's existing oversight and recordkeeping processes.

ITEM 19: MEETING MINUTES TEMPLATE, DELEGATED REVIEW LACKS DEFINED ELIGIBILITY /DOCUMENTATION STANDARDS
DRAFT REFERENCE: "Document all approvals granted by delegated review (may be attached to the minutes as a list). Note any specific issues discussed by the IBC as applicable."
CONCERN: The template does not identify which types of research may be approved through delegated review, who may act as a delegated reviewer, what expertise must be represented, how conflicts of interest must be managed, or whether the full IBC must subsequently ratify the action. Without standardized criteria, institutions may apply delegated review inconsistently, and the minutes may not provide enough information to show why a project was appropriate for review outside the convened committee.
REQUESTED ACTION:
• Define the minimum criteria for delegated review.
• Require the minutes to minimally identify the category of action, basis for delegated review, date of the decision, reviewer role or expertise, approval outcome, conditions imposed, and whether subsequent full-committee action is required.
• Do not require the public version to identify the individual reviewer by name.

ITEM 20: MEETING MINUTES TEMPLATE, HEAVY ADMINISTRATIVE BURDEN
DRAFT REFERENCE: "All official business conducted at the IBC meeting should be documented using this template." The template calls for documentation of institutional information, member attendance, quorum, conflicts, prior business, registrations, delegated reviews, risk assessments, training, occupational-health requirements, biosafety assignments, votes, incidents, inspections, public comments, and additional topics.
CONCERN: The expanded scope of the draft policy, combined with the level of detail required by the meeting minutes template, will substantially increase the administrative time and resources needed to support IBC oversight. Preparing detailed minutes is only one component of this burden. Institutions will also need to review the minutes for accuracy, evaluate information for privacy, proprietary, and security concerns, perform appropriate redactions, obtain IBC approval, maintain the records, and prepare and post a version suitable for public disclosure. As the number of activities requiring IBC oversight increases under the broader draft policy, these requirements will increase workload for IBC members, biosafety staff, PIs, administrative personnel, and other institutional functions supporting review and disclosure. This additional administrative effort should be considered alongside NIH's goal of encouraging compliance. A framework that significantly increases the resources required to administer an IBC program may make voluntary adoption less attractive, even for organizations that otherwise support the draft policy's biosafety principles.

REQUESTED ACTION:
• Exempt non-NIH funded research from mandatory meeting minutes requirements and inclusion may be adopted as voluntary basis only.
• Streamline meeting-minute requirements and ensure that the required level of documentation is proportional to the risk and complexity of the research.
• Provide standardized templates, model language, clear redaction criteria, sample completed minutes, and guidance distinguishing information necessary for the institutional record from information necessary for public disclosure. These measures would reduce unnecessary administrative burden while preserving meaningful documentation, transparency, and biosafety oversight.

ITEM 21: MEETING MINUTES TEMPLATE, ONE DOCUMENTFOR 3 DIFFERENT PURPOSES
DRAFT REFERENCE: "Institutions must prepare IBC meeting minutes that not only serve as the institution's record of the IBC's proceedings but also document for NIH and the public that the IBC is fulfilling its biosafety review and oversight responsibilities."
CONCERN: The template expects one document to function as the complete institutional record, evidence of compliance for NIH, and a public transparency document. These purposes require different levels of technical detail, confidentiality, and accessibility. Information necessary for the institution and NIH to evaluate a risk assessment may not be necessary or appropriate for unrestricted public release.
REQUESTED ACTION:
• Establish two related but distinct records: (1) complete institutional minutes available to NIH through a confidential oversight process when requested, and (2) a limited public-facing summary for research subject to the applicable public-disclosure requirement.
• Specify the public summary describes committee actions, principal hazards, final containment decisions, major safeguards, and approval conditions without reproducing sensitive technical or operational details.
• Agent-specific hazards, containment details, safeguards, technical deliberations, and sensitive conditions should remain in the complete institutional record.

ITEM 22: MEETING MINUTES TEMPLATE, INCIDENT INFORMATION MAY BE UNNECESSARILY DUPLICATED
DRAFT REFERENCE: "Document any incidents (e.g., safety incidents, non-compliance issues); If none - state, 'nothing to report.'" The broader draft policy separately requires institutions to post incident reports publicly using the required incident-reporting template.
CONCERN: Requiring incident information in both publicly posted incident reports and publicly posted IBC meeting minutes creates duplicative documentation without a clear additional transparency benefit. The two records may contain different descriptions or redactions, particularly when the IBC discusses an incident before the investigation is finalized. This also increases the risk of premature disclosure and indirect identification of personnel.
REQUESTED ACTION:
• Permit meeting minutes to reference an incident by a unique identifier and document the IBC's review, determination, and resulting actions.
• Use the separate incident-reporting template as the authoritative institutional and NIH record of the event narrative and final findings. Meeting minutes should reference the report by a unique identifier and document only the IBC’s review and resulting actions.

ITEM 23: MEETING MINUTES TEMPLATE, OCC HEALTH REQUIREMENTS
DRAFT REFERENCE: "Document any required occupational health requirements including, but not limited to: Vaccination requirements; Respiratory protection; Periodic review of any medical surveillance; Post-exposure response procedures."
CONCERN: Protocol-level occupational-health requirements can reveal information about expected exposure routes, agent consequences, specialized medical countermeasures, or the health requirements of a small and identifiable employee group. Detailed discussion may also create a risk of disclosing protected medical information.
REQUESTED ACTION:
• The public-facing summary should state only that applicable occupational-health requirements were reviewed and incorporated into the approval. Specific surveillance, vaccination, respiratory-protection, medical, and post-exposure requirements should remain in confidential institutional records.

ITEM 27: “ANY COMPLIANCE VIOLATIONS AT ANY BSL/ABSL” AND THE LACK OF REPORTING GUIDANCE
DRAFT REFERENCE: Section III-B, IBC Functions (reportable incidents include "Any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approval, or failure to obtain NIH approval for lowering biocontainment for research, when required"); Draft Incident Reporting Template
CONCERN:
• The draft policy does not say whether "compliance violations" means violations of the draft policy only, or also violations of requirements enforced by other oversight bodies, such as the Federal Select Agent Program, OSHA, other federal agencies, or state and local authorities. The two examples given are illustrative, not limiting.
• If the broader reading applies, the same event would be reported to multiple bodies with different timelines, definitions and content, and then posted publicly. That duplicates existing oversight and risks inconsistent records of the same event.
• No reporting guidance. The Incident Reporting Template does not appear to include a section or instructions specific to compliance violations. Its fields are built around physical events such as exposures, spills and equipment failures. Institutions therefore have no guidance on what to submit for a compliance event, and the template does not fit one.
• Disproportionate treatment of administrative lapses. Because the term is undefined and applies at any biosafety level, an administrative lapse, such as a late IBC renewal under the three-year approval cycle, could carry the same 24-hour clock and public posting as an exposure event.
REQUESTED ACTION:
• Limit this category to violations of the policy, and enumerate the specific violations that are reportable.
• State that violations reportable to and handled by another oversight body (for exam

6. Other feedback relevant to this resource: CLARIFY VAGUE AND OPEN-ENDED REQUIREMENTS
The draft repeatedly uses terms that leave institutions without objective implementation criteria, including 'as appropriate,' 'as applicable,' 'as needed,' and 'other pertinent information.' The same concern applies to the boundaries of reportable incidents and required institutional disclosures.
• NIH should replace open-ended qualifiers with decision criteria, examples, required data elements, and clear exclusions.
• NIH should release implementation resources with enough time for institutional review and implementation before the effective date.

PUBLIC-DISCLOSURE SAFEGUARDS FOR HIGH-CONTAINMENT PROGRAMS
Requiring public links to institutional biosafety procedures, rosters, training information, incident reports, and information about high-containment capabilities could aggregate security-sensitive information in a single public location.
• NIH should allow institutions to provide detailed program information to NIH through nonpublic channels and limit public disclosure to a high-level statement of compliance. This is a primary value proposition of the NBDSAC, and we recommend that the NIH leverage the NBDSAC function to reduce policy-imposed vulnerabilities generated by the new NIH draft biosafety policy.
• NIH should establish explicit exemptions and redaction provisions for information that could reasonably be expected to reveal research priorities, capabilities, vulnerabilities, or operational details associated with biodefense, medical countermeasure development, public health preparedness, or other activities supporting national security interests, which are not otherwise protected information. When public reporting is necessary, NIH should provide a system for public reporting to promote consistency across reporting entities.
• NIH should consult with appropriate federal law-enforcement and national security partners with biological-threat and WMD responsibilities when establishing public-disclosure, redaction, and withholding requirements, to ensure the Policy does not inadvertently create exploitable security vulnerabilities.

In addition to these comments, please refer to the submitted attachment for a more detailed discussion of the concerns and recommended actions for NIH consideration. For clarity, these associated concerns are as follows:

ITEM 5: “OTHER PERTINENT INFORMATION REQUESTED BY NIH”
DRAFT REFERENCE: Section III-A, Responsibilities of the Institution (final bullet: "other pertinent information requested by NIH"), in the Biosafety Assurance submission requirements.

CONCERN: The Assurance must list its required elements, but this bullet adds an unlimited category on top of them. The draft policy does not say what NIH may request, why, how often, or how quickly the institution must respond. This matters because NIH approval of the Assurance is a precondition for conducting any covered research. An open-ended information request could delay or withhold that approval, with no stated standard for when the Assurance is complete and no review deadline. The institution would have no way to know in advance whether its submission is sufficient.

The word "pertinent" is undefined and is decided by NIH alone. Institutions cannot prepare for, budget for, or plan around a requirement they cannot see. The Assurance is also valid for a limited period (up to four years), so the uncertainty recurs at each renewal. Additionally, NIH could request security-sensitive or proprietary information, such as facility design, inventories, personnel details or sponsor-restricted work. The draft policy gives no limits on such requests and no stated protection for what institutions submit.

REQUESTED ACTION:
• Delete "other pertinent information requested by NIH," or replace it with a closed, enumerated list of required Assurance elements.

• If NIH needs to retain authority for follow-up requests, limit it to information necessary to evaluate compliance with a specific provision of the draft policy. NIH should state the purpose of the request in writing.
• Give institutions a reasonable response period, and have NIH act on the Assurance within a fixed review deadline once the listed elements are submitted.
• State that institutions may withhold, or provide in redacted form, security-sensitive, proprietary or sponsor-restricted information, and that NIH will protect submitted information from public release to the extent permitted by law, consistent with the request in Item 1.

ITEM 6: NIH REVIEW AND RESPONSE TIMELINES, “IN A TIMELY MANNER”
DRAFT REFERENCE: Section III-D, Responsibilities of the National Institutes of Health (bullets on "[r]eviewing requests for lowering containment levels in a timely manner" and "[r]eviewing and responding in a timely manner to reports of incidents subject to the Policy"; related bullets on determining containment levels for emerging, novel or zoonotic agents, approving or withdrawing Assurances, and verifying institutional incident responses)

CONCERN: The draft policy imposes specific deadlines on institutions, including a 24-hour notification and a 30-day full report for certain incidents. NIH's own obligations are limited to "a timely manner," which the draft policy does not define. The obligations are not reciprocal, and institutions cannot plan around an undefined standard. NIH determinations are gating steps. Research cannot start under an unapproved Assurance, and requests to lower containment or to determine containment for emerging, novel or zoonotic agents remain pending with the NIH. Without a deadline, a delay on NIH's side can stall research indefinitely, with no stated mechanism to escalate or appeal. Transparent and predictable NIH review timelines would improve accountability, reduce administrative burden, and support efficient oversight without reducing biosafety protections.

For incidents, NIH's response and its verification of the institution's corrective action have no stated timeframe. Institutions cannot close out an incident, confirm that corrective actions are accepted, or know whether NIH will require further action. If public posting is retained, the incident report template calls for posting NIH's final response, so an open-ended NIH response time leaves incidents open on the public record.

As written, the draft policy does not provide an expedited review pathway for urgent circumstances. This includes emerging public health concerns, sponsor-driven timelines, or situations where a delayed review could adversely affect critical research activities.

REQUESTED ACTION:
• Require NIH to notify the institution whether a submission is complete or identify all known deficiencies needed to begin a substantive review.
• Define "timely manner" in the draft policy with fixed timeframes for each NIH action. For example: acknowledge receipt of an incident report within 5 business days and provide an initial response within 30 days; act on containment-lowering requests within 60 days; act on Assurances within 90 days of a complete submission.

• Require NIH to provide periodic status updates for reviews and maintain a mechanism for institutions to track the status of pending submissions.
• Provide an interim path when NIH misses a deadline. Institutions should be able to continue approved work under IBC oversight while an Assurance is pending. For containment requests, work stays at the existing containment level until NIH acts, and the institution can request a status update and escalation.
• Set a deadline for NIH to verify an institution's incident response or state what additional action is required. Provide a way to close out an incident once corrective actions are accepted.
• Establish a documented process, standard and appeal path before NIH restricts or withdraws approval of an Assurance, including written notice of the basis and a reasonable opportunity to respond.
• Require NIH to publish its performance against these timeframes in the NIH Annual Incident Summary Report.
• Establish a formal escalation process for expedited review when needed, such as for emerging public health concerns.

ITEM 26: OPEN-ENDED NIH INTERPRETIVE AUTHORITY AND RELIANCE ON LATER GUIDANCE
DRAFT REFERENCE: Section III-D, Responsibilities of the NIH (bullets on "[p]romulgating requirements and guidance necessary to implement the NIH Biosafety Policy," "[i]nterpreting this Policy for cases in which the Policy does not specifically assign containment levels," restricting or withdrawing approval of Assurances, and verifying and directing institutional incident responses); Compliance and Enforcement ("including, but not limited to"); Draft Incident Reporting Template ("additional measures to be taken as appropriate"); NOT-OD-26-112 (Risk Group classifications and other requirements to be provided as implementation resources)

CONCERNS:
• Requirements set outside the draft policy. The draft policy leaves key requirements to later guidance and NIH interpretation. These include Risk Group classifications, containment and training requirements for certain work, and containment for agents the draft policy does not assign. Institutions are asked to comment on a draft policy whose operative details are not yet defined, and those details could change without further public input.
• Standards defined after the fact. Several terms that determine what is reportable and what counts as compliance are undefined, including "significant risk to human health," "incident," "any compliance violations," and "timely manner." NIH's authority to interpret the draft policy and to verify that an institution's response "is appropriate" would give those terms their practical meaning case by case, after events occur.
• Interpretation, enforcement, and standard-setting in one party. NIH issues guidance, interprets gaps, judges compliance, and decides on enforcement, with no stated appeal path, deadline, or requirement to publish its interpretations. Institutions cannot know in advance what will satisfy NIH.
• Compliance exposure. Compliance is a term and condition of award, and enforcement can affect future funding. An institution acting in good faith on a reasonable reading could face action if NIH later reads the draft policy differently.
• Open-ended consequences. "Including, but not limited to" and "as appropriate" leave the range of NIH's required actions and enforcement responses undefined.
• Inconsistent application. Without published interpretations, NIH could treat similar facts differently

across institutions, and institutions could not learn from one another's determinations.

REQUESTED ACTION:
• Place in the draft policy text, not in later guidance, the elements that determine scope, review tier, containment, reporting, and compliance. These include Risk Group classifications and the definitions listed in the related items.
• Provide for public notice and comment before implementation resources or guidance that create or change requirements take effect, and state that such guidance is not binding unless it has gone through that process.
• Require NIH to publish its interpretations and determinations of general applicability, and to give written reasons for individual determinations.
• Provide a good-faith compliance provision: an institution that acts on a reasonable, documented interpretation of the draft policy or of published NIH guidance will not face enforcement for that interpretation.
• Establish a process for institutions to request a written interpretation from NIH, with a response deadline, and a reconsideration and appeal path for adverse determinations.
• Provide advance notice and a reasonable transition period when NIH guidance changes requirements, and limit retroactive application.
• Replace "including, but not limited to" and "as appropriate" with defined lists of possible actions and the circumstances for each.

Description: Attached is the summary of all of the comments

Battelle Memorial Institute Response to Request for Information: Draft NIH Biosafety Policy for Research Involving Biohazards

Policy	Request for Information on Draft NIH Biosafety Policy for Research Involving Biohazards
Notice	NOT-OD-26-112
Comment deadline	October 19, 2026
Submitted by	Battelle Memorial Institute

Introduction

Battelle Memorial Institute (Battelle) is an independent, nonprofit applied science and technology organization whose mission is to advance scientific discovery and innovation for the benefit of society through research, development, education, and the responsible application of science. For nearly a century, Battelle has conducted research addressing challenges in public health, national security, environmental stewardship, and other fields where the safe and responsible conduct of research is essential.

Battelle's comments are informed by decades of experience conducting biological research and managing the associated scientific, biosafety, biosecurity, operational, and regulatory responsibilities necessary to support complex research programs. Battelle's experience includes research, development, testing, and evaluation activities supporting medical countermeasures, biodefense and CBRNE preparedness efforts, force health protection, and public health readiness initiatives intended to address emerging biological and chemical threats.

Consistent with its mission and longstanding commitment to the responsible conduct of research, Battelle offers the following observations and recommendations for consideration as NIH refines the Draft NIH Biosafety Policy for Research Involving Biohazards. The comments focus on institutional scope, regulatory clarity, public disclosure requirements, incident-reporting expectations, alignment with existing federal oversight programs, and implementation considerations, with particular attention to minimizing unintended operational, administrative, security, and compliance impacts.

Item 1: Public disclosure of program details through the Biosafety Assurance Submissions

Draft reference: Section III-A (Assurance submissions: weblinks "to the maximum extent possible" to procedures, a continuously updated IBC roster, minutes, processes for how biosafety risks are managed, incident reports, training synopses; whether the institution conducts BSL-3/4 research).

Concern: The Assurance would direct the public to a consolidated profile of each institution, including where high-containment work is conducted. This information supports transparency, but it is equally useful to those who wish to target personnel, disrupt operations, or gain inside knowledge of how a program functions.

Procedures and incident reports are written for a technical audience and do include the context needed to understand them. However, the general public is unlikely to have the specialized biosafety knowledge to interpret that context accurately, so these documents are likely to be misread or misinterpreted. Continuous updating and long retention increase both risks. The draft policy contains no express authority to withhold security-sensitive material from the public weblinks.

Requested action:

- Remove the expectation that the Assurance submissions link to public postings of procedures, processes for how biosafety risks are managed, rosters, minutes, training synopses and incident reports.
- Allow institutions to provide this information to NIH confidentially, with public disclosure limited to a high-level institutional attestation of compliance.
- Do not require public identification of BSL-3/4 or GDMO capability at the institution level.
- State expressly that institutions may withhold security-sensitive information, and require that NIH protect submitted Assurances from public release to the extent permitted by law.
- Allow institutions to submit the same information already submitted to other federal regulatory programs (e.g., the Federal Select Agent Program) rather than creating duplicate or conflicting information.

Item 2: Public posting of incident reports and corrective actions

Draft reference: Section III-B, IBC Functions ("Posting all incident reports on a public-facing webpage"); Section III-A (public availability for a minimum of five years); Draft Incident Reporting Template (Redaction and Posting)

Concern: The draft policy requires every incident report to be posted publicly, including lower-risk events that are not reportable to NIH. Reports must remain posted for at least five years. Incident reports and the corrective actions they describe necessarily show how an institution's operations, controls and response procedures work. That detail can give malicious actors inside information about sensitive operations. Incident reports are written for a technical audience and do include the context needed to understand them. However, the general public is unlikely to have the specialized biosafety knowledge to interpret that context accurately. A routine, well-managed event can therefore be misread or misinterpreted as a failure. That can create unwarranted concern and may discourage candid reporting of near-misses. The redaction standard is narrow (limited to proprietary or private information and information that would directly compromise institutional or national security), and each institution sets its own criteria.

Additionally, candid reporting of incidents and near-misses is essential to an effective biosafety program; requirements that publicly name the Principal Investigator and the institution may further suppress the reporting needed to identify trends, evaluate safeguards, and prevent recurrence.

Requested action:

- Remove the requirement to publicly post individual incident reports and corrective actions.

- Achieve transparency instead through the NIH Annual Incident Summary Report (Section III-D) and de-identified, aggregate analysis, so the public sees trends without institution-level operational detail.
- If any posting is retained, limit it to NIH-reportable incidents that meet defined criteria. Use summary-level, delayed posting. Do not require corrective-action detail. Give institutions explicit authority to withhold security-sensitive information.

Item 3: "Incident" and "significant risk to human health" are undefined, and "any incident" at BSL-3/ABSL-3 and BSL-4/ABSL-4 is open-ended

Draft reference: Section III-B, IBC Functions (reportable incidents "pose a significant risk to human health"; "any incident" at BSL-3/ABSL-3 or BSL-4/ABSL-4; 24-hour notification to NIH)

Concern: Section III-B states that reportable incidents are those that "pose a significant risk to human health." The draft policy defines neither "incident" nor "significant risk to human health," and it gives no objective test for either. The list then covers "any incident" at BSL-3/ABSL-3 and BSL-4/ABSL-4. The list is introduced with "including," but "any" combined with an undefined term can reasonably be read to capture every event at those levels, regardless of risk. The word "any" also contradicts the stated "significant risk" threshold. The likely results are subjective and inconsistent determinations across institutions, over-reporting, and a 24-hour clock applied to events that do not pose a significant risk to human health.

Requested action:

- Define "incident" in the draft policy with objective criteria.
- Define "significant risk to human health" and use it as the single threshold for every reportable category.
- Replace "any incident" at BSL-3/ABSL-3 and BSL-4/ABSL-4 with a closed, enumerated list of reportable event types. Examples are confirmed or potential laboratory-acquired infection, overt exposure (as defined by NIH), and loss of containment with potential for exposure.
- Provide decision criteria and examples for events below the threshold. State that these are documented and handled internally under IBC oversight rather than reported to NIH or publicly posted.

Item 4: "Biological agent inventory and security issues that may have public health consequences"

Draft reference: Section III-B, IBC Functions (BSL-3/ABSL-3 and BSL-4/ABSL-4 incident list)

Concern: The phrase "may have public health consequences" is speculative and has no objective test, because almost any inventory or security event could arguably meet it. Inventory and security events involving select agents and toxins are already governed by the Federal Select Agent Program (42 CFR Part 73; 7 CFR Part 331; 9 CFR Part 121). A parallel 24-hour NIH report, followed by public posting, duplicates that oversight. It also publicizes security information that is normally protected and could be exploited by malicious actors.

Requested action:

- Exclude agents regulated under the Federal Select Agent Program from this category, and defer to that program and other applicable security regimes.
- If any version is retained, replace "may have public health consequences" with an objective standard.
- State explicitly that inventory, security and access-control information is excluded from any public posting.

Item 5: "Other pertinent information requested by NIH"

Draft reference: Section III-A, Responsibilities of the Institution (final bullet: "other pertinent information requested by NIH"), in the Biosafety Assurance submission requirements.

Concern: The Assurance must list its required elements, but this bullet adds an unlimited category on top of them. The draft policy does not say what NIH may request, why, how often, or how quickly the institution must respond. This matters because NIH approval of the Assurance is a precondition for conducting any covered research. An open-ended information request could delay or withhold that approval, with no stated standard for when the Assurance is complete and no review deadline. The institution would have no way to know in advance whether its submission is sufficient.

The word "pertinent" is undefined and is decided by NIH alone. Institutions cannot prepare for, budget for, or plan around a requirement they cannot see. The Assurance is also valid for a limited period (up to four years), so the uncertainty recurs at each renewal. Additionally, NIH could request security-sensitive or proprietary information, such as facility design, inventories, personnel details or sponsor-restricted work. The draft policy gives no limits on such requests and no stated protection for what institutions submit.

Requested action:

- Delete "other pertinent information requested by NIH," or replace it with a closed, enumerated list of required Assurance elements.
- If NIH needs to retain authority for follow-up requests, limit it to information necessary to evaluate compliance with a specific provision of the draft policy. NIH should state the purpose of the request in writing.
- Give institutions a reasonable response period, and have NIH act on the Assurance within a fixed review deadline once the listed elements are submitted.
- State that institutions may withhold, or provide in redacted form, security-sensitive, proprietary or sponsor-restricted information, and that NIH will protect submitted information from public release to the extent permitted by law, consistent with the request in Item 1.

Item 6: NIH review and response timelines ("in a timely manner")

Draft reference: Section III-D, Responsibilities of the National Institutes of Health (bullets on "[r]eviewing requests for lowering containment levels in a timely manner" and "[r]eviewing and responding in a timely manner to reports of incidents subject to the Policy"; related bullets on determining containment levels for

emerging, novel or zoonotic agents, approving or withdrawing Assurances, and verifying institutional incident responses)

Concern: The draft policy imposes specific deadlines on institutions, including a 24-hour notification and a 30-day full report for certain incidents. NIH's own obligations are limited to "a timely manner," which the draft policy does not define. The obligations are not reciprocal, and institutions cannot plan around an undefined standard. NIH determinations are gating steps. Research cannot start under an unapproved Assurance, and requests to lower containment or to determine containment for emerging, novel or zoonotic agents remain pending with the NIH. Without a deadline, a delay on NIH's side can stall research indefinitely, with no stated mechanism to escalate or appeal. Transparent and predictable NIH review timelines would improve accountability, reduce administrative burden, and support efficient oversight without reducing biosafety protections.

For incidents, NIH's response and its verification of the institution's corrective action have no stated timeframe. Institutions cannot close out an incident, confirm that corrective actions are accepted, or know whether NIH will require further action. If public posting is retained, the incident report template calls for posting NIH's final response, so an open-ended NIH response time leaves incidents open on the public record.

As written, the draft policy does not provide an expedited review pathway for urgent circumstances. This includes emerging public health concerns, sponsor-driven timelines, or situations where a delayed review could adversely affect critical research activities.

Requested action:

- Require NIH to notify the institution whether a submission is complete or identify all known deficiencies needed to begin a substantive review.
- Define "timely manner" in the draft policy with fixed timeframes for each NIH action. For example: acknowledge receipt of an incident report within 5 business days and provide an initial response within 30 days; act on containment-lowering requests within 60 days; act on Assurances within 90 days of a complete submission.
- Require NIH to provide periodic status updates for reviews and maintain a mechanism for institutions to track the status of pending submissions.
- Provide an interim path when NIH misses a deadline. Institutions should be able to continue approved work under IBC oversight while an Assurance is pending. For containment requests, work stays at the existing containment level until NIH acts, and the institution can request a status update and escalation.
- Set a deadline for NIH to verify an institution's incident response or state what additional action is required. Provide a way to close out an incident once corrective actions are accepted.
- Establish a documented process, standard and appeal path before NIH restricts or withdraws approval of an Assurance, including written notice of the basis and a reasonable opportunity to respond.
- Require NIH to publish its performance against these timeframes in the NIH Annual Incident Summary Report.

- Establish a formal escalation process for expedited review when needed, such as for emerging public health concerns.

Item 7: Application of the draft policy to non-NIH-funded research at any institution receiving any NIH funding

Draft reference: Section II, Scope ("This Policy is also applicable to non-NIH funded research that is conducted on or after [effective date] at an institution that receives any NIH funding"; the Scope also applies "regardless of NIH funding level or funding mechanism"); Compliance and Enforcement (institutions "shall ensure that any research conducted at or sponsored by the institution, irrespective of the source of funding, shall comply with this Policy"); General Definitions, "Biomedical research" (includes "non-NIH funded research that is conducted at an institution that receives any NIH funding"); Section III-A (no research subject to the draft policy may be conducted until NIH approves the institution's Biosafety Assurance)

Concern:

- Overreach. The draft policy already defines "NIH-supported research" as all research funded in whole or in part by NIH. It then extends the draft policy to every other research program at the institution. A single NIH award of any size, through any mechanism, would pull in the institution's entire portfolio, including work funded by other federal agencies and private clients. Institutions that draw funding from many sources are affected most and are disproportionately impacted. The connection between receipt of NIH funding for one project and regulation of unrelated research activities elsewhere within the institution is not clearly articulated.
- Contractors, collaborators and shared facilities. The draft policy also, as written, does not address how obligations apply to contractors, subcontractors, collaborators, partnerships, or shared facilities. There may be conflicting oversight obligations when only some participating organizations receive NIH funding.
- Existing oversight. Much of this work is already overseen by its own sponsors and regulators, especially at the federal level. These sponsors often require comparable biosafety documentation, reviews and incident reporting. Applying NIH requirements on top creates duplicate review and reporting, and it can produce conflicting findings and timelines. The deference language in Section II refers only to "another federal agency," does not define the "approvals or other applicable clearances" required, and does not address private sponsors.
- Financial burden. Institutions would have to submit and maintain an Assurance, put additional protocols through IBC review, complete incident reports, and publicly post information for programs that NIH does not fund. The notice materials do not include a cost estimate for this expansion, and the costs would fall on institutions and, through them, on non-NIH sponsors. Low-risk non-NIH-funded projects may become subject to the same administrative burdens as activities that present substantially greater biosafety risk.
- Delay. The draft policy bars all covered research until NIH approves the Assurance, and it sets no review deadline for NIH. Because the draft policy reaches non-NIH work, an NIH delay could stall sponsor programs that have fixed contract schedules and deliverables, even though NIH is not funding or directing the work.

- Sponsor restrictions. Public posting and disclosure requirements can conflict with confidentiality, proprietary-information, controlled unclassified information, export-control and security terms in sponsor agreements. An institution cannot unilaterally breach those terms, and the draft policy provides no mechanism to reconcile them.
- Classified work. The draft policy does not address government-classified research. Classified programs cannot be disclosed in an Assurance, in IBC minutes or incident reports, or on a public website. The existence of such work may itself be restricted. The draft policy's redaction language covers information that would "directly compromise institutional or national security," but only for the public posting of reports. It does not address the Assurance, IBC review, NIH reporting, or the personnel and clearances needed to review such material. Without accommodation, institutions with classified programs cannot show compliance without violating their security obligations.
- Enforcement exposure on non-NIH work under undefined standards. The draft policy states that failure to comply "may provide a basis for enforcement actions, including, but not limited to, additional special terms and conditions, or termination," and that enforcement "may affect future funding decisions for the recipient institution." Because the draft policy extends to non-NIH-funded work, an institution's NIH funding could be put at risk over research that NIH does not fund. The standards against which compliance would be judged are not yet defined. Examples include what "pose[s] a significant risk to human health"; what counts as an "incident" or as "any compliance violations"; what "a timely manner" means (the same draft policy that leaves NIH's response time undefined); what "other pertinent information" must be provided; and what redactions are "appropriate and allowable." Institutions cannot reliably demonstrate compliance with terms they must interpret on their own, and two institutions could reach different, equally reasonable readings. The phrase "including, but not limited to" also leaves the range of possible enforcement actions open. Enforcement consequences this significant should rest on requirements that are clear, objective and known in advance.
- Competitive impact. The draft policy could create an uneven competitive landscape. Institutions that receive NIH funding would incur additional oversight, reporting, Assurance, and public disclosure obligations across their research portfolio, while institutions conducting comparable non-NIH-funded work without NIH funding would not. This may discourage participation in NIH-funded research and create incentives to separate research activities among affiliated entities.
- Commercial sponsor impact. Commercial sponsors may be unwilling to place proprietary research at institutions subject to mandatory public posting or NIH oversight on non-NIH-funded work. This could reduce research opportunities and increase costs for institutions and sponsors.

<u>Requested action:</u>

- Limit the draft policy to NIH-supported research as the draft policy already defines it. Delete the non-NIH-funded sentence in Section II, the "irrespective of the source of funding" language in Compliance and Enforcement, and the non-NIH clause in the "Biomedical research" definition.
- Continue to encourage voluntary adoption for other research, as the Voluntary Compliance section already provides.
- If NIH retains institution-wide application, require that it apply at the project or facility level, not through one institution-wide gate. Exempt research already overseen by another federal agency or by

sponsor-required biosafety oversight from NIH review, incident reporting and public posting, and accept the other oversight body's documentation as meeting NIH's requirement.

- If NIH retains institution-wide application, exempt non-NIH-funded projects already underway before the effective date.
- Add an express provision for classified research. It should state that classified work is overseen under applicable national security requirements. It should also say that nothing in the draft policy requires disclosure of classified information, including the existence of the work, in an Assurance, in IBC records, or in any report to NIH or the public. Provide a compliance pathway that does not depend on disclosure.
- Provide an exemption or a defined process for sponsor-restricted work (proprietary, controlled unclassified, export-controlled or contractually confidential), with no public posting.
- Clarify whether the draft policy applies to contractors, subcontractors, and shared facilities.
- Do not gate research that NIH does not fund on NIH approval of the Assurance. If any non-NIH work stays in scope, set fixed NIH review deadlines and allow work to continue under existing sponsor and IBC oversight while review is pending.
- Publish a cost and burden analysis specifically for the expansion to non-NIH-funded research.
- Define the terms listed above in the draft policy before any enforcement authority applies, and tie each enforcement action to a specific, enumerated requirement.
- Limit enforcement actions affecting NIH funding to NIH-supported research. Do not link NIH funding decisions to compliance on non-NIH-funded work.
- Establish a graduated, documented enforcement process: written notice of the specific requirement allegedly not met, a reasonable opportunity to respond and correct, and an appeal path before any special terms, termination or funding consequence.
- Provide a good-faith compliance provision. Institutions that make a reasonable, documented interpretation of an undefined term would not face enforcement while NIH is still issuing implementation guidance.
- Replace "including, but not limited to" with a defined list of possible enforcement actions.

Item 8: Reporting of "potential releases" from facility or equipment failures "even when redundant systems were functioning properly"

Draft reference: Section III-B, IBC Functions (reportable incidents at BSL-3/ABSL-3 or BSL-4/ABSL-4: "potential releases involving facility and/or equipment failures, even when redundant systems were functioning properly, to address the possibility of risk to personnel and the community and prevent future occurrences"); Section III-C (voluntary, confidential near-miss reporting to the National Biosafety Data and Safety Analysis Center)

Concern:

- Circular trigger. Redundant systems exist to prevent releases. When they function properly, no release occurs. The clause nevertheless requires a report of a "potential release," so the trigger depends on something that did not happen. The draft policy does not define "potential release," so institutions cannot tell what counts. Requiring a report when backup systems perform exactly as designed treats successful risk mitigation as evidence of a reportable incident rather than a demonstration that the

containment system functioned properly. In addition, public reporting of events in which containment was never lost may create the appearance of a biosafety failure where none occurred.

- Inconsistent with the "significant risk" threshold. Section III-B limits reportable incidents to those that "pose a significant risk to human health." A failure that a redundant system contained does not meet that threshold, and the draft policy does not reconcile the two.
- Undefined scope. "Facility and/or equipment failures" has no limits. Without a definition, a wide range of routine faults and maintenance events could become reportable. That would drive over-reporting, inconsistent determinations across institutions, and a heavy burden of review, reporting and public posting. A high volume of low-risk reports could divert attention from events involving actual exposures, releases, or containment failures.
- Disincentive to good design and candid reporting. Treating a successful backup as a reportable event discourages institutions from recording and discussing equipment faults openly. That works against NIH's stated aim of learning from near-misses.
- Inconsistent with the voluntary near-miss framework. The draft encourages voluntary, confidential reporting of near-misses and secondary failures to the National Biosafety Data and Safety Analysis Center, and it says NIH will not use that data for enforcement unless there was an environmental release or lab acquired infection. This clause requires essentially the same kind of event to be reported to NIH, and posted publicly, under the mandatory process.
- Overlap with existing oversight. Facility and equipment performance is already governed by existing biosafety, facility-maintenance and, where applicable, Federal Select Agent Program requirements. The draft does not say how this reporting relates to them.

Requested action:

- Delete "even when redundant systems were functioning properly." Events in which secondary or redundant controls performed as designed should not be reportable to NIH.
- Limit this category to equipment or facility failures that result in a loss of containment, an actual release, or an exposure, or that create a documented potential for exposure that safeguards did not prevent. Define "potential release" with objective criteria.
- Handle failures in which redundant systems held as internal events, reviewed by the IBC and documented locally, as the draft already does for lower-risk incidents that "must be reported to and addressed by the IBC" but not NIH.
- Direct near-miss and secondary-failure information to the voluntary, confidential framework in Section III-C, with the protections stated there. Do not make it a mandatory, publicly posted report.
- Define "facility and/or equipment failure" using objective, risk-based criteria such as loss of primary containment, loss of negative pressure beyond established limits, failure of decontamination systems, or failure resulting in actual exposure or release. Align any retained reporting with existing federal requirements, so one event does not trigger parallel reports.

Item 9: Records retention and duration of public availability

Draft reference: Section III-A (records retention "in accordance with Section 8.4.2 of the NIH GPS … 2 CFR 200.334," and "IBC meeting minutes and incident reports must be publicly posted for a minimum of five years";

incident reports and minutes containing award-related records "must be made available to the public during this time if requested")

Concern:

- Separate obligations, mismatched periods. The draft policy ties records retention to the federal baseline of three years under 2 CFR 200.334 and NIH GPS 8.4.2, then sets a separate five-year public posting requirement. The two are different obligations, and the draft policy gives no safety rationale for the longer public period.
- Exceeds the federal baseline. 2 CFR 200.334 provides that Federal agencies "may not impose any other record retention requirements" except for specified circumstances. The draft policy does not identify which exception supports a five-year requirement.
- No defined start date. The draft policy does not say when the five years begin (posting date, meeting or incident date, or award closeout). Incident reports can span multiple protocols at different stages of the grant cycle, so institutions cannot determine when posting may end.
- Unclear scope. The draft policy uses both "publicly posted" and "made available to the public … if requested." It does not say which applies to which records, or what happens when a record is only partly award-related.
- Added risk and cost. A longer public window increases the aggregation and security risks as well as hosting, review and redaction costs. It also prolongs the risk of misinterpretation by non-expert audiences. NIH already has access to retained records for as long as they are kept, so extended public posting is not needed for NIH oversight.
- Non-NIH work. For research that NIH does not fund, no federal award exists, so the retention baseline does not apply, yet the five-year public requirement would.
- Record accuracy. The draft policy does not address whether corrected reports, amended findings, or updated corrective actions replace prior versions, nor does it explain which versions remain publicly available. Retaining outdated information for extended periods could create inaccurate public record, especially as biosafety practices and facility capabilities change over time.

Requested action:

- Align any public availability period with the existing three-year baseline, or remove the fixed minimum, and keep records for NIH access under existing retention rules.
- If NIH retains a longer public period, state the safety rationale and the legal basis, including which provision of 2 CFR 200.334 permits it.
- Define when the period starts and ends, and how it applies to records spanning multiple protocols or awards.
- Clarify which records must be continuously posted and which need only be provided on request, and permit removal after the period ends.
- Clarify when and how records are updated throughout the reporting process.
- Exempt non-NIH-funded research from the public availability requirement.

Item 10: Definition of "Biomedical research" as research "within the mission of the NIH"

Draft reference: General Definitions, "Biomedical research" ("Research on a topic that is within the mission of the NIH," including non-NIH-funded research conducted at an institution that receives NIH funding); Section II, Scope. The draft policy repeatedly conditions applicability on "research," but does not provide a general definition of "research" itself, and the separate definition of "laboratory research" addresses only where the work occurs.

Concern: For institutions that conduct multidisciplinary research, these provisions create uncertainty regarding independently sponsored defense, commercial, veterinary, environmental, product-development, validation, quality-control, surveillance, and similar activities. Applicability also turns on "known or potential risk to human health," which the draft policy does not define, so it is unclear how these activities are treated where human health is not the focus of the work.

Because coverage determines whether an Assurance, IBC review, incident reporting and public posting apply, and because enforcement can affect NIH funding, institutions need to know in advance which activities are covered. The same definition is also the basis for extending the draft policy to non-NIH-funded research.

Requested action:

- Provide objective criteria and representative examples for determining when independently sponsored work is sufficiently within the NIH mission to constitute covered biomedical research.
- Define "research" for policy applicability and distinguish it from operational testing, validation, quality control, manufacturing support, diagnostics, training, and other related biological activities.
- Establish a formal process for institutions to request written applicability or scope determinations for ambiguous projects and activities.

Item 11: Reliance on other federal oversight, including the Federal Select Agent Program

Draft reference: Section II, Scope states, "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." Section V-A separately recognizes that the Federal Select Agent Program oversees the possession, use, and transfer of Select Agents and Toxins and states, "All entities must follow the requirements laid out in the Select Agent Regulations."

Concern: Although Section V-A names the Federal Select Agent Program, the draft policy does not say whether it is a qualifying program under Section II, what approvals or clearances are required, whether other federal oversight replaces or supplements NIH requirements, or which NIH requirements continue to apply.

Requested action:

- Identify qualifying agencies and programs, including the Federal Select Agent Program, and define the approvals or clearances required.

- Establish a formal reliance or equivalency framework that identifies which NIH requirements are satisfied by another federal oversight program and how duplicative or conflicting requirements will be resolved.
- State whether work under another federal agency's oversight remains subject to NIH incident reporting, public posting and IBC review.

Item 12: Three-year de novo approval requirement

Draft reference: Section III-B (IBC Functions) requires the IBC to periodically review approved research and states that approval may not exceed three years, at which time a de novo registration submission and review is required. Changes that may affect the original biosafety assessment must be reviewed before implementation.

Concern: The draft policy does not define the frequency, scope, or documentation for periodic review. Requiring a complete de novo submission every three years for unchanged, compliant, lower-risk research may divert resources from higher-risk oversight without a corresponding improvement in risk control.

Requested action:

- Define periodic-review expectations based on risk, compliance history, complexity, and whether material changes have occurred.
- Permit streamlined renewal or administrative continuation for unchanged, compliant research and reserve full de novo review for material changes, elevated-risk work, significant incidents, or compliance concerns.

Item 13: Incident Template - "Redaction and Posting of Incident Reports"

Draft reference: "Information that is widely available from other public sources such as institutional webpages, publications describing an investigator's research, or public grants databases (e.g., names of IBC members and PIs, biological agents used in research, including Select Agents, grant numbers) is not considered private or proprietary and may not be redacted from reports."

Concern: This provision does not appear to allow institutions to consider the context created by aggregation of otherwise publicly available information. Individual pieces of information may already be public, while combining those data within an incident report could provide substantially greater insight into research activities, biological agents, personnel, incidents, and institutional vulnerabilities.

The explicit inclusion of "biological agents used in research, including Select Agents" raises an especially important security concern.

Requested action:

- Permit institutions to consider the cumulative or aggregated security implications of information when determining whether redaction is appropriate, even when individual elements exist elsewhere in the

public domain. Security review should consider the context of the complete incident report, rather than only whether each individual data element has previously been made public.
- Before finalizing the public-disclosure and redaction requirements, obtain review from appropriate federal partners responsible for preventing biological threats and weapons of mass destruction (WMD)-related misuse, including the aggregation of otherwise public information.

Item 14: Incident Template - Principal Investigator identification and staff identification

Draft reference: "Incident reports should not include any personally identifiable identification of individuals involved in the incident (aside from the Principal Investigator's name)." The incident narrative subsequently instructs institutions: "Who was involved in the incident/violation, including others present at the incident location? Note - do not identify individuals by name. Provide only position titles..."

Concern: The template protects the identities of personnel involved in an incident but specifically excludes the PI from that protection. Because these reports are required to be publicly posted, naming the responsible PI could unintentionally associate an individual with an incident even when the PI was not present, directly involved, or responsible for the causal factors.

Requested action:

- Remove the requirement of the disclosure of PI names from any publicly posted incident report.
- If NIH oversight requires PI identification, allow institutions to provide the PI identity to NIH while using a role or position designation in the public version, unless identification serves a defined public-health purpose.

Item 15: Incident Template - Reporting requirements not calibrated to incident severity

Draft reference: "All fields must be fully completed in every final report. If an element does not apply, indicate not applicable."

Concern: The template requires the same general level of completion regardless of whether an incident involves:

- A contained BSL-2 exposure with no injury
- A documentation lapse
- A failure of redundant equipment with no release
- A potential laboratory-acquired infection
- A community release
- A major BSL-3 or BSL-4 containment event

A uniform reporting structure does not reflect a meaningful tiered approach based on risk.

Requested action:

- Establish two levels of reporting: 1) Internal institutional record for nonreportable events, with optional de-identified submission to NBDSAC and 2) NIH report for events meeting defined NIH reporting thresholds, with enhanced fields incorporated only when warranted by the severity of the event.

- Assignment to an NIH reporting tier should determine the information provided confidentially to NIH and should not, by itself, require public posting.

Item 16: Incident Template - Other agency reporting is captured but coordination is not

Draft reference: "Has a report of this incident been made to other agencies? If so, indicate: CDC, USDA, FDA, EPA, OSHA."

Concern: The checkbox documents that another report occurred but does not address duplication, conflicting timelines, inconsistent definitions, or whether NIH will accept information already submitted to another federal agency. This creates the possibility of multiple reports containing similar information in different formats.

Requested action:

- Accept an equivalent report submitted to another federal oversight agency as satisfying NIH reporting requirements for overlapping elements and require only supplemental information that is uniquely necessary for NIH oversight.
- Coordinate definitions, timelines, and required data elements with other agencies to reduce duplicative oversight.

Item 17: Meeting Minutes Template - Shifts substantial local deliberation into a federal/public record

Draft reference: "Institutions must prepare IBC meeting minutes that ... document for NIH and the public that the IBC is fulfilling its biosafety review and oversight responsibilities." Points to consider: "In general, the minutes should offer sufficient detail to serve as a record of all major points of discussion and the committee's rationale for decisions." "Key points made in discussion, motions of the committee, and whether those motions were approved should be documented."

Concern: Meeting minutes traditionally document committee action, but this template may transform detailed local technical deliberations into publicly available records used by NIH to judge compliance. Effective local oversight depends on committee members being able to discuss uncertainty openly without concern that preliminary statements will be interpreted externally as final findings.

Requested action:

- Require minutes to document the final risk assessment approval, committee decision, and approval conditions.
- A public-facing summary should state the general category of review, confirm that the required assessment occurred, and document the committee's final action without disclosing sensitive technical or operational details. Do not require a detailed public account of every technical discussion, preliminary concern, or alternative considered.

Item 18: Meeting Minutes Template - May unintentionally include general safety matters unrelated to covered biohazards

Draft reference: "All official business conducted at the IBC meeting should be documented using this template." Examples provided: "review of incidents, laboratory inspection reports, reports from safety personnel related to the safe conduct of research at the institution, personnel training, review of policies, etc."

Concern: These examples could encompass a broad range of institutional safety matters that are not necessarily connected to research involving biohazards covered by the draft policy. Laboratory inspections, training discussions, and reports from safety personnel frequently address chemical, physical, radiological, ergonomic, animal-handling, and general occupational hazards. Requiring these discussions to appear in the public IBC record could extend the effective scope of the template beyond biosafety oversight.

Requested action:

- Specify that only the portions of inspection reports, safety discussions, training matters, or policy reviews that materially relate to research subject to the draft policy must be included in the required minutes, and that other institutional safety business remains within the institution's existing oversight and recordkeeping processes.

Item 19: Meeting Minutes Template - Delegated review lacks defined eligibility and documentation standards

Draft reference: "Document all approvals granted by delegated review (may be attached to the minutes as a list). Note any specific issues discussed by the IBC as applicable."

Concern: The template does not identify which types of research may be approved through delegated review, who may act as a delegated reviewer, what expertise must be represented, how conflicts of interest must be managed, or whether the full IBC must subsequently ratify the action. Without standardized criteria, institutions may apply delegated review inconsistently, and the minutes may not provide enough information to show why a project was appropriate for review outside the convened committee.

Requested action:

- Define the minimum criteria for delegated review.
- Require the minutes to minimally identify the category of action, basis for delegated review, date of the decision, reviewer role or expertise, approval outcome, conditions imposed, and whether subsequent full-committee action is required.
- Do not require the public version to identify the individual reviewer by name.

Item 20: Meeting Minutes Template - Heavy administrative burden

Draft reference: "All official business conducted at the IBC meeting should be documented using this template." The template calls for documentation of institutional information, member attendance, quorum, conflicts, prior business, registrations, delegated reviews, risk assessments, training, occupational-health requirements, biosafety assignments, votes, incidents, inspections, public comments, and additional topics.

Concern: The expanded scope of the draft policy, combined with the level of detail required by the meeting minutes template, will substantially increase the administrative time and resources needed to support IBC oversight. Preparing detailed minutes is only one component of this burden. Institutions will also need to review the minutes for accuracy, evaluate information for privacy, proprietary, and security concerns, perform appropriate redactions, obtain IBC approval, maintain the records, and prepare and post a version suitable for public disclosure. As the number of activities requiring IBC oversight increases under the broader draft policy, these requirements will increase workload for IBC members, biosafety staff, PIs, administrative personnel, and other institutional functions supporting review and disclosure.

This additional administrative effort should be considered alongside NIH's goal of encouraging compliance. A framework that significantly increases the resources required to administer an IBC program may make voluntary adoption less attractive, even for organizations that otherwise support the draft policy's biosafety principles.

Requested action:

- Exempt non-NIH funded research from mandatory meeting minutes requirements and inclusion may be adopted as voluntary basis only.
- Streamline meeting-minute requirements and ensure that the required level of documentation is proportional to the risk and complexity of the research.
- Provide standardized templates, model language, clear redaction criteria, sample completed minutes, and guidance distinguishing information necessary for the institutional record from information necessary for public disclosure. These measures would reduce unnecessary administrative burden while preserving meaningful documentation, transparency, and biosafety oversight.

Item 21: Meeting Minutes Template - One document being used for three different purposes

Draft reference: "Institutions must prepare IBC meeting minutes that not only serve as the institution's record of the IBC's proceedings but also document for NIH and the public that the IBC is fulfilling its biosafety review and oversight responsibilities."

Concern: The template expects one document to function as the complete institutional record, evidence of compliance for NIH, and a public transparency document. These purposes require different levels of technical detail, confidentiality, and accessibility. Information necessary for the institution and NIH to evaluate a risk assessment may not be necessary or appropriate for unrestricted public release.

Requested action:

- Establish two related but distinct records: (1) complete institutional minutes available to NIH through a confidential oversight process when requested, and (2) a limited public-facing summary for research subject to the applicable public-disclosure requirement.
- Specify the public summary describes committee actions, principal hazards, final containment decisions, major safeguards, and approval conditions without reproducing sensitive technical or operational details.

- Agent-specific hazards, containment details, safeguards, technical deliberations, and sensitive conditions should remain in the complete institutional record.

Item 22: Meeting Minutes Template - Incident information may be unnecessarily duplicated

Draft reference: "Document any incidents (e.g., safety incidents, non-compliance issues); If none - state, 'nothing to report.'" The broader draft policy separately requires institutions to post incident reports publicly using the required incident-reporting template.

Concern: Requiring incident information in both publicly posted incident reports and publicly posted IBC meeting minutes creates duplicative documentation without a clear additional transparency benefit. The two records may contain different descriptions or redactions, particularly when the IBC discusses an incident before the investigation is finalized. This also increases the risk of premature disclosure and indirect identification of personnel.

Requested action:

- Permit meeting minutes to reference an incident by a unique identifier and document the IBC's review, determination, and resulting actions.
- Use the separate incident-reporting template as the authoritative institutional and NIH record of the event narrative and final findings. Meeting minutes should reference the report by a unique identifier and document only the IBC's review and resulting actions.
- Refer to Items 13-16 for the incident-reporting template.

Item 23: Meeting Minutes Template - Occupational health requirements

Draft reference: "Document any required occupational health requirements including, but not limited to: Vaccination requirements; Respiratory protection; Periodic review of any medical surveillance; Post-exposure response procedures."

Concern: Protocol-level occupational-health requirements can reveal information about expected exposure routes, agent consequences, specialized medical countermeasures, or the health requirements of a small and identifiable employee group. Detailed discussion may also create a risk of disclosing protected medical information.

Requested action:

- The public-facing summary should state only that applicable occupational-health requirements were reviewed and incorporated into the approval. Specific surveillance, vaccination, respiratory-protection, medical, and post-exposure requirements should remain in confidential institutional records.

Item 24: Clarify that BSO responsibilities may be fulfilled through oversight of qualified institutional programs and personnel

Draft reference: Section III-B, Biosafety Officer (BSO) Requirements and Duties

Concern: Section III-B is written as a single BSO personally responsible for conducting inspections, investigating incidents, and performing other operational functions. The draft policy does not recognize that these activities are often carried out by a multidisciplinary team or institutional program operating under the direct oversight of the BSO.

Requested action:

- Clarify that the BSO is responsible for the oversight, coordination, and effectiveness of these functions and that inspections, investigations, assessments, and related activities may be conducted by appropriately qualified personnel operating under the BSO's authority.
- Include the following language: "The BSO's duties may be carried out directly by the BSO or through the oversight, coordination, and review of appropriately qualified institutional personnel operating under the authority of the BSO."

Item 25: Clarify authority and responsibilities for biocontainment determinations

Draft reference: Section III-B, IBC Functions (independent risk assessment of required biocontainment levels and notification of the required biocontainment level); Section III-C, Responsibilities of the PI (initial risk assessment and selection of biocontainment levels).

Concern: The draft policy assigns containment-related risk assessment responsibilities to both the PI and the IBC but does not clearly identify who is responsible for proposing, evaluating, and approving the final biocontainment level. The requirement for both an initial PI risk assessment and an independent IBC risk assessment could be interpreted as requiring multiple independent evaluations of the same hazards without clarifying how disagreements should be resolved.

Requested action:

- Clarify that the PI is responsible for conducting the initial risk assessment and proposing the appropriate containment level and risk mitigation strategy.
- Clarify that the BSO may provide technical review and recommendations regarding containment, containment practices, and risk mitigation measures.
- Clarify that the IBC is responsible for reviewing the proposed containment level, considering the recommendations of the BSO and other subject matter experts as appropriate, and approving the final institutional biocontainment level.
- Specify how differing assessments among the PI, BSO, and IBC should be resolved and identify the institutional authority responsible for the final determination.

Item 26: Open-ended NIH interpretive authority and reliance on later guidance

Draft reference: Section III-D, Responsibilities of the NIH (bullets on "[p]romulgating requirements and guidance necessary to implement the NIH Biosafety Policy," "[i]nterpreting this Policy for cases in which the Policy does not specifically assign containment levels," restricting or withdrawing approval of Assurances, and verifying and directing institutional incident responses); Compliance and Enforcement ("including, but not

limited to"); Draft Incident Reporting Template ("additional measures to be taken as appropriate"); NOT-OD-26-112 (Risk Group classifications and other requirements to be provided as implementation resources)

Concerns:

- Requirements set outside the draft policy. The draft policy leaves key requirements to later guidance and NIH interpretation. These include Risk Group classifications, containment and training requirements for certain work, and containment for agents the draft policy does not assign. Institutions are asked to comment on a draft policy whose operative details are not yet defined, and those details could change without further public input.
- Standards defined after the fact. Several terms that determine what is reportable and what counts as compliance are undefined, including "significant risk to human health," "incident," "any compliance violations," and "timely manner." NIH's authority to interpret the draft policy and to verify that an institution's response "is appropriate" would give those terms their practical meaning case by case, after events occur.
- Interpretation, enforcement, and standard-setting in one party. NIH issues guidance, interprets gaps, judges compliance, and decides on enforcement, with no stated appeal path, deadline, or requirement to publish its interpretations. Institutions cannot know in advance what will satisfy NIH.
- Compliance exposure. Compliance is a term and condition of award, and enforcement can affect future funding. An institution acting in good faith on a reasonable reading could face action if NIH later reads the draft policy differently.
- Open-ended consequences. "Including, but not limited to" and "as appropriate" leave the range of NIH's required actions and enforcement responses undefined.
- Inconsistent application. Without published interpretations, NIH could treat similar facts differently across institutions, and institutions could not learn from one another's determinations.

Requested action:

- Place in the draft policy text, not in later guidance, the elements that determine scope, review tier, containment, reporting, and compliance. These include Risk Group classifications and the definitions listed in the related items.
- Provide for public notice and comment before implementation resources or guidance that create or change requirements take effect, and state that such guidance is not binding unless it has gone through that process.
- Require NIH to publish its interpretations and determinations of general applicability, and to give written reasons for individual determinations.
- Provide a good-faith compliance provision: an institution that acts on a reasonable, documented interpretation of the draft policy or of published NIH guidance will not face enforcement for that interpretation.
- Establish a process for institutions to request a written interpretation from NIH, with a response deadline, and a reconsideration and appeal path for adverse determinations.
- Provide advance notice and a reasonable transition period when NIH guidance changes requirements, and limit retroactive application.

- Replace "including, but not limited to" and "as appropriate" with defined lists of possible actions and the circumstances for each.

Item 27: "Any compliance violations at any BSL/ABSL" and the lack of reporting guidance

Draft reference: Section III-B, IBC Functions (reportable incidents include "Any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approval, or failure to obtain NIH approval for lowering biocontainment for research, when required"); Draft Incident Reporting Template

Concern:

- Undefined scope. The draft policy does not say whether "compliance violations" means violations of the draft policy only, or also violations of requirements enforced by other oversight bodies, such as the Federal Select Agent Program, OSHA, other federal agencies, or state and local authorities. The two examples given are illustrative, not limiting.
- Duplicative reporting. If the broader reading applies, the same event would be reported to multiple bodies with different timelines, definitions and content, and then posted publicly. That duplicates existing oversight and risks inconsistent records of the same event.
- No reporting guidance. The Incident Reporting Template does not appear to include a section or instructions specific to compliance violations. Its fields are built around physical events such as exposures, spills and equipment failures. Institutions therefore have no guidance on what to submit for a compliance event, and the template does not fit one.
- Disproportionate treatment of administrative lapses. Because the term is undefined and applies at any biosafety level, an administrative lapse, such as a late IBC renewal under the three-year approval cycle, could carry the same 24-hour clock and public posting as an exposure event.

Requested action:

- Limit this category to violations of the policy, and enumerate the specific violations that are reportable.
- State that violations reportable to and handled by another oversight body (for example, the Federal Select Agent Program or OSHA) are not separately reportable to NIH, or accept the other body's report as satisfying NIH's requirement.
- Add compliance-violation fields and instructions to the Incident Reporting Template, or issue separate reporting guidance.
- Distinguish administrative lapses from events that pose a risk to human health, provide a cure period for administrative lapses, and exclude them from the 24-hour notification and from public posting.

Item 28: IBC meeting minutes template creates serious security risks to personnel, institutions and national interests

Draft reference: Section III-B, IBC Functions (IBC meeting minutes prepared using the required template and posted on a public-facing webpage); Draft IBC Meeting Minutes Template and Points to Consider ("The names of IBC members may not be redacted from the minutes"; "The names of the PIs may not be redacted from minutes"; information such as "names of IBC members and PIs, biological agents used in research, including Select Agents, grant numbers ... may not be redacted from the IBC minutes"; redaction permitted only for information "where disclosure would directly compromise institutional or national security")

Concern:

- A roadmap to people and programs. Under the template, each set of posted minutes would publicly link named PIs and IBC members to:
    - their institution, city and state
    - the specific agents and toxins they work with, including Select Agents
    - the animal models used
    - the containment level and safeguards in place
    - the training and occupational health requirements that apply to them
- The template also calls for the meeting date, start and end times, whether the meeting is in person or virtual, the platform used, and the date, time and platform of the next meeting. Together, these elements identify who does the work, what the work is, where it happens, and when and how the oversight committee meets.
- Targeting by extremist groups. Research that uses animals, and particularly research with nonhuman primates, has long been a focus of animal rights extremism. Researchers, staff and their families have faced harassment, intimidation, threats and attacks. The template asks for animal models, animal procedures, animal-handling training (including "primate safety"), and the names of the investigators and committee members involved, and it prohibits redacting those names. Publicly posting this information turns a compliance record into a target list. It exposes individuals and their families to harassment and violence, and it exposes institutions to disruption and property damage.
- Collection by foreign competitors and adversaries. NIH already requires public posting of approved IBC meeting minutes for research subject to the current 2024 NIH Guidelines. The proposed policy would extend that framework beyond recombinant or synthetic nucleic acid research to a broader range of biological agents, toxins, prions, genetically modified organisms, and other covered biohazards, while the required template would standardize the disclosure of agents, modifications, methods, safeguards, personnel, and unpublished supporting information. This expanded and standardized record could be aggregated at scale by foreign governments and competitors to identify emerging U.S. research directions, institutional capabilities, and sensitive technical information before publication, patenting, or commercialization.
- Expanded dual-use information hazard. Although NIH already requires public posting of IBC minutes, the proposed policy would broaden the covered research and standardize disclosure of agent characteristics, genetic modifications, attenuation methods, experimental manipulations, risk-mitigation measures, and other technical details. Individual disclosures may appear limited, but their aggregation across meetings and institutions could reveal both the biological hazards under study and the controls used to manage them, increasing the potential for misuse.
- Additional risk: disclosure of vulnerabilities. The template asks for laboratory inspection results, deficiencies and their correction, incidents and follow-up, conditional approvals (for example, biological safety cabinet certification), building maintenance, and waste-handling practices that differ from institutional policy. Publicly listing where controls were found deficient tells an adversary where an institution may be weakest.
- Additional risk: social engineering and cyber targeting. Names, roles and expertise of committee members and investigators, together with meeting schedules, virtual platforms, and descriptions of

institutional IT systems under development, support targeted phishing, impersonation, and attempts to access meetings or institutional systems.

- Additional risk: insider and access risk. Identifying which staff are trained for high-containment work, which personnel require specific vaccinations, and which individuals have access to particular agents tells a malicious actor whom to approach, pressure or recruit.
- Additional risk: aggregation at national scale. One institution's minutes may seem harmless in isolation. Minutes from every covered institution, posted in a standard format and kept for at least five years, form a national dataset of where agents are held and who works with them. Automated and AI-assisted tools make that dataset easy to compile, search and map. Copies remain in web archives and third-party collections after the institution removes the original. The redaction standard does not account for this aggregation, and it treats information as public if any piece of it appears elsewhere.
- Additional risk: inconsistency with Select Agent protections. Information about who possesses Select Agents and where is treated as security-sensitive under the Federal Select Agent Program. The template expressly prohibits redacting Select Agent identities from public minutes. Because entities must comply with both, the template creates a direct conflict with existing federal security practice.
- Additional risk: weaker oversight and workforce. Non-affiliated community members serve on IBCs as volunteers. Publicly listing their names alongside high-risk research will discourage qualified people from serving, and may discourage scientists and staff from working in high-consequence research fields. That weakens the oversight the draft policy seeks to strengthen.
- Redaction standard is too narrow to address these risks. Redaction is limited to information whose disclosure would "directly compromise" security. Most of the risks above come from aggregation, indirect identification and cumulative exposure, which "directly" does not capture. NIH itself recognizes that "specific facility addresses may be security sensitive," but it requires the same institutions to publish the people, agents and practices inside those facilities.
- Existing posting is not a reason to expand content. Public posting of minutes already applies to meetings on or after June 1, 2025. The mandatory template, its content requirements, and its prohibitions on redaction would substantially increase the sensitivity of what is posted. Because posting is already in place, these content requirements need to be reconsidered before they are finalized.

<u>Requested action:</u>

- Remove the prohibitions on redacting the names of IBC members and PIs. Allow institutions to identify members by role and expertise in public minutes, and to provide names to NIH.
- Remove the prohibition on redacting biological agents and Select Agents. Allow agent identities to be described by risk group or general category in public minutes.
- Replace "directly compromise institutional or national security" with a standard that allows redaction of information that could reasonably be expected to endanger personnel, facilities or security, individually or in combination with other information.
- Do not require public posting of meeting times, meeting format or platform, next-meeting details, inspection deficiencies, incident details, occupational health requirements, or references to unpublished data.

- Limit public minutes to a summary of committee actions and confirmation that required reviews occurred. Retain full minutes at the institution and provide them to NIH on request.
- Exempt minutes for research involving Select Agents, BSL-3/ABSL-3 or BSL-4/ABSL-4 work, and nonhuman primates from public posting, and provide them to NIH confidentially.
- Before finalizing the template, conduct a formal security review with federal law enforcement, intelligence and research security partners, including an assessment of aggregation and automated collection. Publish the results.
- Align the template with Federal Select Agent Program information protections and with federal research security policy.

Item 29: IBC meeting minutes template may require public release of export-controlled information and controlled unclassified information

Draft reference: Section III-B, IBC Functions (IBC meeting minutes prepared using the required template and posted on a public-facing webpage); Draft IBC Meeting Minutes Template and Points to Consider (Project Overview to include agent name and characteristics, sources and nature of nucleic acid sequences, modifications made to attenuate agents or render them replication-incompetent, supporting published or unpublished data, and experimental manipulations; redaction limited to proprietary or private information and information "where disclosure would directly compromise institutional or national security"; names of PIs, IBC members, and biological agents, including Select Agents, "may not be redacted")

Concern:

- Export-controlled technology. Federal export control regulations control certain biological agents and toxins, along with certain technology for their development or production. The template's Project Overview, Risk Assessment and Biosafety Level fields call for the kind of technical detail that can fall within those controls. Examples include genetic modifications, attenuation methods, sequence sources, agent characteristics and experimental procedures. Posting that information on a public website could be an unauthorized release of controlled technology. Once posted, it becomes available to anyone, including foreign persons and restricted parties, and cannot be retrieved.
- Fundamental research does not cover all covered work. Much academic research falls under the fundamental research exclusion from export controls. Contract and sponsored research often does not, particularly where the sponsor restricts publication or dissemination. The draft policy's reach extends to non-NIH-funded work (see Item 7). Under it, institutions would have to publicly post minutes for research that is export-controlled because it is not fundamental research.
- Controlled unclassified information (CUI). Research performed under federal contracts may involve CUI, which must be safeguarded and may not be publicly released unless the designating agency has decontrolled it. Institutions are not authorized to decontrol CUI. A minutes template that requires public summaries of such research, and prohibits redacting key elements, places institutions in direct conflict with their contractual and regulatory obligations to protect CUI.
- The redaction standard does not cover either category. The template permits redaction of proprietary or private information and information whose disclosure would "directly compromise institutional or national security." It does not mention export-controlled information or CUI. Neither category is

necessarily "private" or "proprietary," and neither requires showing a direct security compromise. As written, institutions have no clear authority to redact information they are legally required to protect.

- Conflicting legal obligations. Institutions cannot satisfy both requirements. Complying with the template could violate export control or CUI requirements, and withholding the information could be treated as noncompliance with the draft policy and affect NIH funding. The draft policy provides no mechanism to resolve the conflict.
- Deemed exports within the IBC itself. Before anything is posted, IBC review places technical information in front of all committee members, including non-affiliated community members. If a member is a foreign person, sharing export-controlled technology with them may itself require an export license. The draft policy's membership and review requirements do not account for this.
- Lasting loss of control. Information released publicly is collected, archived and redistributed by third parties. A later correction, redaction or removal does not undo the release.

Requested action:

- State expressly that nothing in the draft policy, the meeting minutes template or the incident reporting template requires public disclosure of export-controlled information or controlled unclassified information.
- Add export-controlled information, CUI, and information restricted by a federal sponsor or contract to the categories that institutions may redact or withhold, without requiring a showing of direct security compromise.
- For research that is not fundamental research, or that involves export-controlled information or CUI, permit minutes to record only that the review occurred and the approval decision, and provide full minutes to NIH through an appropriately controlled channel.
- Allow IBC review of export-controlled or CUI-related research to be conducted by members eligible to receive that information, and state that this satisfies the draft policy's membership and review requirements.
- Coordinate the templates and redaction guidance with the Departments of Commerce and State and the CUI Executive Agent before the draft policy is finalized.

Item 30: Preserve influenza-specific safeguards against unintended genomic reassortment

Draft reference: Section IV, experiments involving influenza viruses; current NIH Guidelines, Section III-D-7, Experiments Involving Influenza Viruses.

Concern: The draft policy assigns containment for influenza research according to the Risk Group of the virus contributing the majority of genomic segments and establishes enhanced containment for certain 1918 H1N1, human H2N2, and HPAI H5N1 experiments. However, it does not expressly require institutions to evaluate and control the risk of unintended genomic reassortment when different influenza strains are studied concurrently or sequentially in shared rooms, equipment, animal spaces, or supporting systems.

Influenza viruses possess segmented genomes, and concurrent exposure to different strains can create conditions for reassortment. Available federal guidance, such as the BMBL, does not comprehensively address

temporal and spatial separation for concurrent or sequential recombinant or synthetic influenza research. USDA APHIS guidance addresses concurrent HPAIV and 1918 influenza studies, but NIH should establish a broader framework for identifying and mitigating unintended reassortment risks involving other consequential strain combinations. This gap illustrates why Risk Group classification alone cannot replace a protocol-specific assessment of the resulting agent, concurrent research activities, shared spaces and equipment, and credible pathways for unintended reassortment.

Requested action:

- Retain explicit influenza-specific safeguards requiring IBC assessment of unintended genomic reassortment during recombinant, synthetic, reverse-genetics, and reassortant influenza research. The assessment should address concurrent and sequential work, temporal or spatial separation, shared rooms, equipment and animal spaces, validated decontamination between activities, and documented clearance before another influenza strain is introduced.
- Publish influenza-specific implementation guidance identifying the existing safeguards that will be retained, modified, relocated, or discontinued and establishing minimum controls for strain combinations capable of producing a more pathogenic, transmissible, or otherwise consequential reassortant.

Item 31: Retain a stable and transparent Risk Group classification resource

Draft reference: Section IV, Categories of Oversight for Research Based on Risk; Section V, Risk Assessment and Mitigation for Research Involving Biohazards; NOT-OD-26-112 and the Draft Policy Table of Changes regarding Risk Group classifications as implementation resources.

Concern: The draft policy relies on Risk Groups to determine oversight pathways and inform risk assessment but does not retain the agent classification lists contained in the current NIH Guidelines. Moving these classifications to a separate implementation resource creates uncertainty regarding where the authoritative classifications will reside, how changes will be reviewed and communicated, and whether classifications could change without stakeholder notice.

Risk Groups provide an important starting point for biological risk assessment, but they do not independently determine the appropriate containment level for a specific protocol. Final BSL or ABSL determinations must also consider the characteristics of the resulting agent, genetic modifications, experimental procedures, routes of exposure, scale, aerosol potential, animal work, and available safeguards.

Requested action:

- Retain the Risk Group classification lists in the draft policy or in a formally controlled, publicly accessible implementation resource that identifies the authoritative classification, revision date, supporting rationale, and effective date of each material change.
- Establish a transparent process for modifying Risk Group classifications that includes scientific review, advance notice to affected institutions, publication of the basis for the change, and a reasonable implementation period.

- Clarify that Risk Group classification is a starting point for protocol-specific risk assessment and does not automatically determine the final BSL or ABSL, which should be approved by the IBC based on the agent, modifications, procedures, and other relevant risk factors.

Battelle appreciates the opportunity to provide comments on the Draft NIH Biosafety Policy for Research Involving Biohazards. These recommendations are intended to improve regulatory clarity, preserve risk-based institutional oversight, coordinate NIH requirements with existing federal frameworks, protect sensitive research and personnel information, and ensure that transparency measures do not displace the preventive controls necessary for effective biosafety.

Battelle respectfully requests NIH's consideration of these comments as it develops the final policy, templates, and implementation materials.

273. The University of Vermont

I am responding: On behalf of an organization

Name: Sara Cahan

Name of Organization: The University of Vermont

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Fundamental and clinical biomedical research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Subject: Comments on Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Introduction

The University of Vermont (UVM) appreciates the opportunity to respond to the Request for Comment regarding the Draft NIH Biosafety Policy for Research Involving Biohazards, the Draft Incident Reporting Template, and the Draft Meeting Minutes Template.

UVM is a public R1 research institution conducting a diverse portfolio of biomedical, translational, agricultural, environmental, and public health research supported by federal, state, foundation, and industry sponsors. The University's research activities span basic, applied, and clinical investigations and include collaborations with academic, government, healthcare, and industry partners. Accordingly, UVM maintains a comprehensive research oversight framework designed to support scientific discovery, ensure regulatory compliance, manage biological and research-related risks, and maintain public trust.

We share the NIH's commitment to the modernization of biosafety oversight in research and welcome clearer authority, stronger institutional standing, and a well-defined mandate that allows risk-based management of all biological hazards.

UVM believes the proposed policy would benefit from further refinement to improve clarity, reduce interpretive ambiguity, and reinforce the principle of risk-based oversight that underpins effective biosafety governance. Below, we outline in more detail the basis for our concerns and recommended remedies, organized by the relevant section(s) of the draft policy.

Scope of the NIH Guidelines
Sections I- A to 1-D
UVM supports the proposal's emphasis on focusing IBC resources on higher-risk activities. However, without defined risk categories, review thresholds, and objective decision criteria, institutions may apply the framework inconsistently, potentially increasing oversight burden for lower-risk research and reducing consistency across the research enterprise.

Impact: UVM generally supports the expanded scope because it aligns with the University's existing integrated approach to biosafety oversight. However, absent clear risk-based guidance, the proposal may substantially increase institutional administrative workload for activities presenting minimal biosafety risk. The impact is therefore positive in concept but potentially negative operationally.

Recommendation: ***To enable effective and efficient compliance with the proposed framework, UVM recommends providing more detailed guidance regarding risk categories, exclusions, and review thresholds*****.**

Institutional Submissions to NIH

Section IV-B-2-a
Section IV-B-2-c
UVM supports replacing annual roster submissions with a four-year institutional assurance model, which shifts oversight to functional elements of the institutional biosafety program rather than administrative reporting. However, the proposal provides limited detail regarding assurance review criteria, approval timelines, updates between submission cycles, and the consequences of material changes to institutional programs.

Impact: This change is expected to have a generally positive impact by reducing recurring administrative reporting requirements and allowing greater focus on substantive program elements. The benefits, however, will depend on clear expectations regarding assurance review criteria, submission requirements, amendment procedures, and the management of institutional program changes.

Recommendation: ***To avoid uncertainty over compliance requirements, UVM recommends that the policy provide sufficient detail to operationally guide institutional activities*****.** Having clear expectations would improve predictability, reduce uncertainty, and support consistent implementation across the research enterprise.

IBC Functions: Incident Reporting

Section IV-B-2-b-(7)
Appendix G-II-B-2-k
Appendix G-II-C-2-q
Appendix G-II-D-2-k
UVM is concerned that the proposed incident reporting provisions expand reportable events to include administrative and procedural issues that have been, historically, appropriately managed through existing institutional oversight processes. While supporting transparency, UVM believes the proposed public disclosure requirements may inadvertently discourage reporting of near misses and minor incidents that are essential to a strong culture of safety.

UVM is also concerned that the proposed reporting framework may create substantial intra-institutional and inter-institutional overlap, resulting in increased administrative

burden, duplicative effort, and unclear lines of responsibility. Within institutions, a single event may require parallel review and reporting through multiple oversight functions, including biosafety, human subjects protections, animal care and use, occupational health and safety, environmental health and safety, compliance, and research administration offices. Across institutions, collaborative research arrangements may require multiple organizations to independently assess, investigate, document, and report substantially the same event, creating redundant processes and increasing the potential for inconsistent reporting.

These overlapping requirements may also adversely affect research collaboration. Effective multi-institutional research depends upon clearly defined responsibilities, efficient information sharing, and streamlined oversight processes. A reporting framework that generates duplicative reviews, overlapping reporting obligations, or multiple requests for the same information may increase administrative complexity and create barriers to scientific collaboration without providing a commensurate increase in biosafety protections.

UVM is additionally concerned about the potential impact on public-private research partnerships. Corporate research partners may be particularly sensitive to reporting requirements that could result in public scrutiny of preliminary investigations, minor incidents, or events that are ultimately determined to pose minimal biosafety risk. Absent clear risk-based reporting thresholds and appropriate protections of sensitive information, expanded reporting obligations may discourage industry participation in collaborative research and increase the administrative and legal complexity of such partnerships.

Impact: This provision is likely to have the most significant operational impact. Expanded reporting requirements may duplicate existing obligations across biosafety, human subjects, animal care and use, occupational health, environmental health and safety, compliance, and research administration programs. Without clear coordination mechanisms and risk-based reporting thresholds, the proposal may increase administrative burden, complicate multi-institutional collaborations, and discourage industry partnerships without a corresponding improvement in biosafety outcomes.

Recommendation: ***UVM recommends limiting public reporting to incidents with significant biosafety, biosecurity, or public health implications while preserving institutional mechanisms for managing lower-risk events.*** UVM offers as examples the NASA Aviation Safety Reporting System (ASRS) and the National Fire Fighter Near-Miss Reporting System; two nationally recognized incident and near-miss reporting systems that emphasize confidentiality, learning, trend analysis, and system improvement rather than

punitive or publicly scrutinized reporting frameworks, thereby encouraging candid reporting and broader participation.

Categories of Research (Lowering of Containment)

Section III-A (Applicable Sections)
Section IV-C-1-b
Appendices G, K, and L
UVM is concerned that centralized NIH approval of all initial RG3 and RG4 containment-reduction requests could create a regulatory bottleneck while providing limited additional safety benefit where robust risk assessment and containment data already exist.

The practical challenge is that only a small fraction of projects are likely to present true biosafety concerns, while a far larger number may require preliminary screening to demonstrate that they do not. The resulting requirement to evaluate all proposed and ongoing life sciences research could create a significant new compliance obligation. Institutions would need to invest substantial resources in administration, training, screening, documentation, and review, including for funding proposals that ultimately are not awarded and research projects that never come to fruition.

Impact: Potentially negative. Even though only a small fraction of projects request or require containment-reduction, requiring centralized approval may introduce delays, create new administrative obligations, and require institutions to devote substantial resources to evaluating and documenting activities that ultimately do not warrant additional biosafety oversight.

Recommendation: ***The proposal should include clear approval standards, defined review timelines, and a transparent process for relying on prior NIH determinations to ensure consistent, predictable, and efficient oversight*.**

Delegated Review of Research

Section III-D
Section III-E

UVM notes the proposed delegation authority may unintentionally create inconsistencies in biosafety oversight absent clearly defined eligibility standards and review expectations.

Several proposed categories encompass a very wide spectrum of risk (toxins, viral vectors) and the framework provides limited guidance regarding when delegated review is appropriate versus when full IBC deliberation is warranted.

Impact: Potentially positive. When accompanied by clear eligibility standards and safeguards, delegated review could improve efficiency, reduce unnecessary committee workload, and better align review intensity with actual biosafety risk while preserving oversight quality.

Recommendation: ***The final guidance should establish objective biosafety characteristics that trigger IBC review, minimum reviewer qualifications, documentation standards, and escalation criteria, rather than relying primarily on broad product categories.*** This will promote predictable and consistent oversight nationwide without diminishing the rigor, transparency, or consistency of institutional biosafety oversight.

Clinical Research

Section III-C-1

While UVM supports biosafety oversight of clinical research involving replicating, integrating, shedding, or RG2-or-higher biological agents, the proposed categories require further clarification. Several terms remain broadly defined and may encompass activities with substantially different risk profiles.

Impact: Generally positive if objective review criteria and clear boundaries between biosafety and existing human-subjects oversight functions are established. Absent such clarity, institutions may experience duplicative reviews and inconsistent application of requirements.

Recommendation: ***The final guidance should establish objective risk-based criteria, examples, and review thresholds to promote consistent determinations regarding when IBC review is warranted and to reduce variability between institutions.***

Research Involving Genetically Modified Plants

Section III-D-5
Section III-E-2
Appendix L

UVM supports focusing the proposed Biosafety Policy on activities presenting direct human health risks. However, excluding genetically modified plants from this policy does not mean that they lack oversight altogether, which may not be clear without qualifying language.

Impact: Generally positive. The proposed approach appropriately focuses biosafety oversight on human health risks while allowing institutions to continue applying environmental, agricultural, and other relevant oversight frameworks where warranted.

Recommendation: ***The exclusion of genetically modified plants and plant pathogens that do not cause human disease should be accompanied by clear acknowledgment that such research may still warrant review under other institutional, environmental, agricultural, or regulatory oversight frameworks.***

Required Documentation

Section IV-B-2-b-(7) (IBC)
Section IV-B-7-b (PI submissions to NIH OSP)
UVM supports the objective of improving consistency and information quality through standardized documentation; however, mandatory templates may require manual handling of information already maintained within institutional electronic systems. Institutions utilizing electronic research compliance systems will have to export, reformat, or manually transfer information into mandated templates solely to satisfy formatting requirements, increasing both administrative burden and the risk of human error.

Impact: Strongly negative. Institutions with mature electronic compliance systems may be required to create manual workarounds to satisfy formatting requirements despite already maintaining the required information electronically. A data-element approach would better support consistency while preserving efficiency and reducing opportunities for error.

Recommendation: ***The policy would be strengthened by requiring a standardized set of data elements rather than prescribed document formats.***

Additional Comments

The implementation timeline for these changes remains unclear. The proposal represents a substantial expansion of institutional biosafety oversight responsibilities and cannot reasonably be implemented within a short transition period. Most institutions would require at least 12 to 18 months, and potentially longer, to revise policies and procedures, establish new review pathways, configure electronic compliance systems, recruit and train

personnel, educate investigators, and achieve sustainable compliance with the proposed requirements.

The cumulative impact of these changes on both Institutional Biosafety Committees (IBCs) and institutional administrative offices is likely to be significant. The expanded scope of oversight would increase demands associated with protocol intake and review, pre-award compliance assessments, investigator training, inspections, incident management, recordkeeping, post-approval monitoring, and regulatory reporting. While the proposal appropriately elevates the importance of biosafety oversight, successful implementation will require corresponding investments in personnel, expertise, information systems, and administrative infrastructure.

UVM is particularly concerned that these expanded responsibilities are proposed without accompanying risk stratification criteria, implementation guidance, or a defined transition framework. As a result, institutions may be required to commit substantial resources before the scope of required oversight activities can be consistently interpreted and applied. Greater clarity regarding risk categories, review expectations, implementation milestones, and resource assumptions would improve consistency across institutions and facilitate more effective adoption of the policy.

Without additional guidance and a realistic implementation timeline, institutions may face significant compliance burdens without the desired corresponding improvement in biosafety.

Overall Impact: UVM supports the policy's underlying goals and recognizes that many aspects of the proposal are consistent with practices already employed within mature institutional biosafety programs. However, as currently drafted, the proposal would likely have a net negative operational impact due to expanded administrative burden, overlapping reporting requirements, implementation costs, and the absence of sufficiently defined risk-stratification criteria. Additional guidance, flexibility, and implementation planning would improve both effectiveness and institutional sustainability.

Conclusion

UVM appreciates the opportunity to contribute to this important discussion. These comments are submitted in the spirit of partnership, scientific advancement, and stewardship of public trust. We share the goal of a biosafety framework that protects communities, supports responsible institutional oversight, and enables continued innovation and discovery. We respectfully encourage the adoption of a final policy that is clear, risk-informed, sustainable, and practical to implement, while supporting an evolving research enterprise that advances discovery, safeguards communities, strengthens

institutional responsibility, and promotes the responsible progress of science for years to come.

274. University of North Carolina Charlotte

I am responding: On behalf of an organization

Name: Cathy Moore

Name of Organization: University of North Carolina Charlotte

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Clarification is requested regarding the explicit exclusion of plants from the scope of Section II. Institutional members seek guidance on whether plant research will be subject to a separate companion federal oversight policy, or if this creates a regulatory gap. Further clarification is needed on how the policy governs toxins expressed within plant systems. Under Section II, toxins are explicitly within the scope, while plants are excluded, creating ambiguity over whether toxin expression in plant tissue is considered out of scope due to the plant host, or in scope due to the toxin itself.

The proposed definition of genetic modification in Section II includes “stable alterations into the genome by passaging…” Operational guidance is requested to distinguish routine subculturing from passaging that triggers policy oversight. Institutional members seek clarity on whether routine passaging of organisms triggers review, or if oversight applies strictly to deliberate experimental evolution protocols.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Concerns have been raised regarding the burden placed on environmental sampling and surveillance research (e.g. soil, water, or field sampling), where the risk group or agent identified is inherently unknown or may yield novel or emerging agents. Clarification is requested on whether routine environmental sampling automatically triggers the highest tier of review by both the NIH and IBC. Requiring the highest tier federal review for sampling unknown environmental microbes without a pre-determined risk group creates significant administrative bottlenecks and potential delays for research and training programs.

Section II defines a novel agent or organism as one “not existing in nature, deliberately designed…”. However, the policy lacks operational guidance on the degree of genetic divergence required for a modified organism to cross the threshold from a routine genetic modification to a novel agent. Institutional Biosafety Committees will need clear criteria for what constitutes a novel agent. Without clear boundaries, institutions may default to over-classifying minor genetic variants as novel agents, triggering the highest tier of oversight by both the NIH and IBC, delaying routine research.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Concerns were raised regarding the requirement to publish incident reports directly on public-facing institutional websites and what redactions are allowable. Public exposure with identifying details may create a reporting deterrent, inadvertently discouraging researchers from coming forward to report incidents. Institutional members recommend that incident data and reporting templates be submitted to and maintained within a centralized NIH database (such as the proposed National Biosafety Data and Safety Analysis Center) in a de-identified or restricted format, rather than hosted on public institutional websites.

6. Other feedback relevant to this resource: N/A

275. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: a. Definitions

For the scope of the policy, research involving biohazards is defined as research involving known or potential risk to human health and any of the following:
1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above.

The policy should clarify if this includes the following:
1. Bloodborne pathogens (BBPs): Infectious microorganisms present in human blood and other potentially infectious materials that are capable of causing disease in humans.
2. Environmental samples: Soil, water, air, and other environmental samples that may contain infectious microorganisms or other potentially infectious materials.
3. Materials containing or potentially containing the above: Bloodborne pathogen materials and environmental samples containing agents or materials identified in categories 1 and 2, including materials containing combinations of these hazards.

A clear and comprehensive definition would help institutions consistently determine which research activities fall within the policy's scope.
Overall, the policy could improve on the consistency of terms and definitions.

b. Research Involving Plants

If research involving wild-type and genetically modified plants is not covered by this policy, will NIH clarify whether USDA/APHIS will establish a separate policy or oversight framework for this type of research?

c. Research Conducted in Clinical Settings

Can the Institutional Biosafety Committee (IBC) and Biological Safety Officer (BSO) establish appropriate IBC review and survey requirements for research conducted in clinical settings? Such research may involve different physical environments, workflows, and risk mitigation practices than those used in traditional BSL laboratories. The policy should allow sufficient flexibility to accommodate these differences while maintaining appropriate biosafety oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I would request clarification on the topics below:

a. Research Requiring NIH and IBC Approval Prior to Initiation

1. Will NIH publish the outcomes of its reviews for higher-risk research involving emerging, novel, or zoonotic agents for which a Risk Group (RG) classification or minimum containment level is not currently established in the Biosafety in Microbiological and Biomedical Laboratories (BMBL)?
2. If NIH establishes a determination or containment recommendation through its review process and subsequently publishes that information, would institutions still be required to submit individual protocols for NIH review, or would the published determination eliminate the need for additional NIH review?

b. Research Requiring IBC Review and Approval Prior to Initiation

For research involving toxins listed as Select Agents, does the proposed oversight requirement apply only to quantities exceeding the applicable exemption limits, or would IBC review be required regardless of the quantity?

c. Research Requiring Review and Approval Prior to Initiation That May Be Delegated to an Individual or Subgroup of IBC Members

1. Minor amendments: How will “minor amendment” be defined? For example, would a minor amendment be limited to changes that do not alter the risk assessment or required containment level?
2. IBC membership: Must the individual or subgroup conducting the delegated review consist of voting members of the IBC?
3. Reporting to the full IBC: What is the expectation for an item to be “reported in full” to the IBC? Would written reporting to the full committee satisfy this requirement, or is discussion during the convened IBC meeting expected?

3. Continued utility of Risk Groups: I agree that Risk Group classifications remain an important foundation for biosafety risk assessments and continue to have value under the proposed policy.

However, it would be extremely beneficial to biosafety professionals if the RG classifications were expanded, made publicly accessible, and maintained as a dynamic resource. If Appendix B is no longer available and the BMBL is limited in the agents it assigns risk groups to, then biosafety professionals need a resource that can provide current RG classifications to be the starting point for risk assessments,

which review the agent, practices, and training to assign the BSL for containment and facility requirements. NIH could consider establishing a publicly available list that is updated in a timely manner as NIH completes reviews of emerging, novel, and zoonotic agents. Such a resource would provide institutions with greater consistency and transparency when conducting risk assessments and determining appropriate containment measures.

Risk Group classifications do not equate to Biological Safety Level (BSL). The BMBL provides standard and special microbiological practices, safety equipment, and laboratory facility requirements for each BSL, but it is the institution's IBC that establishes the BSL based on the research risk assessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: IBC Meeting Minutes

a. Documentation of IBC Member Expertise
Requiring IBC meeting minutes to document individual members' expertise may be duplicative, as this information is already included in the institution's publicly available IBC roster. Consider allowing the publicly available roster to satisfy this requirement, provided that the roster sufficiently describes the expertise represented on the committee.

b. Project Descriptions
Principal Investigators (PIs) may have concerns regarding the level of detail required in project overviews included in publicly available IBC meeting minutes. The policy should clarify the expected level of detail while ensuring that proprietary, confidential, or otherwise sensitive information is appropriately protected.

c. Incidents and Inspection Surveys
Documentation of incidents and inspection surveys in publicly available IBC meeting minutes should not contain personally identifiable information. Rather, summaries should provide sufficient information to describe the nature of the event, the associated risk, and the corrective actions taken without identifying individual personnel.

Incident Reporting

Posting incident reports on a public-facing website using the proposed reporting template may present several challenges to consider.

a. Potential Reduction in Reporting
Public disclosure of incident reports may discourage reporting because personnel and institutions could be concerned about the lack of confidentiality. This could result in underreporting of incidents and near misses, ultimately reducing the value of the reporting system as a biosafety learning and prevention tool.

b. HIPAA and Other Confidentiality Requirements
Incident reports may contain information that requires redaction to comply with HIPAA or other

applicable privacy and confidentiality requirements. The policy should clearly distinguish between information that must be submitted to NIH and information that is appropriate for public disclosure.

c. Scope of Incidents Requiring Reporting
The definition of a reportable incident should focus on events relevant to biosafety and biosecurity risks, such as:
• Exposure to a biohazard;
• Release or potential release of a biohazard;
• Laboratory equipment failures that result in or could result in exposure or release; and
• Significant near misses involving biohazardous materials.

Routine occupational safety incidents, such as slips, trips, and falls unrelated to a biohazard, should not be included in the proposed biosafety incident reporting framework.

6. Other feedback relevant to this resource: The proposed three-year renewal cycle is likely to significantly increase the administrative burden on both Principal Investigators and IBCs. Institutions currently operating under a five-year renewal cycle would experience a substantial increase in the frequency of protocol renewals, potentially doubling the IBC workload associated with renewals.

In addition, the primary administrative and technical resource for biosafety review and may require additional staffing or other resources to support the increased workload.

I encourage NIH to consider the administrative implications of the proposed three-year renewal cycle and evaluate whether a risk-based or tiered renewal schedule could achieve the desired level of oversight while minimizing unnecessary administrative burden. A risk-based approach could allow more frequent review for higher-risk research while permitting longer renewal intervals for lower-risk activities that have demonstrated effective oversight and compliance.

276. Brett Haltiwanger

I am responding: On behalf of myself

Name: Brett Haltiwanger

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The current draft states that it covers all biomedical research in laboratory settings involving biohazards but does not sufficiently define biohazards or biomedical research. The scope combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may primarily affect animals, plants, agriculture or the environment, or research involving materials that may affect human health, but are not considered biomedical research (e.g. environmental sciences).

The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Recommend that the scope be broadened to a One Health approach developed in collaboration with other funding agencies to ensure adequate oversight of animal, plant and environmental hazards while minimizing administrative burden.

Toxins: The toxin and protein scope of the policy should be calibrated to meaningful risk. The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses "prions and other self-aggregating proteins" in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

The proposed definition of genetic modification includes passaging, reassortment, and chemical or

radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Genetically modified cells: Human and non-human primate-derived cells are commonly recognized to present potential risk to human health; however, the risk to human health associated with many animal (e.g., murine) or insect cell lines is often ambiguous, negligible and case-specific. We recommend clarification and specific examples of genetically modified and primary cells covered by the policy per Section IV-2. We similarly recommend clarification and examples of well-characterized cell lines as referenced in Section IV-3.

Genetic modification: Considering the potential for unintentional or collateral mutagenesis induced by experiments involving ionizing irradiation and/or chemicals, we suggest adding the term intentional (or a term with similar meaning) to the definition of genetic modification per Section II.
Section IV-2 requires Institutional Biosafety Committee (IBC) review and approval before initiation of a rather broad scope of research involving genetically modified cells, viruses or organisms, other than plants. Conversely, Section IV-3 allows for delegated review of a much more specifically defined subset of research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes. This distinction suggests that NIH intends for IBC review and approval of research involving replication-competent, integrating viral vectors expressing high-risk transgenes; however, the language in Section IV-2 may be interpreted to encompass any genetic modifications not specified in Section IV-3. For example, if vertebrate animals are considered organisms, this suggests that all genetically modified vertebrates (e.g., transgenics) may require IBC review and approval. In addition, Section IV-2 may be interpreted to apply to any and all cells not involving plants (e.g., animal and insect cells). We recommend that Section IV-2 be modified to more explicitly describe the nature of research involving genetic modifications subject to IBC review and approval before initiation (e.g., research involving genetically modified cells, viruses or organisms deemed potentially harmful to human health or subject to Section IV-3).

Transgenic animals: Recommend providing a definition of transgenic as referenced in Sections IV-3 and V-A.

Clarify oversight related to genetically modified and/or transgenic animals. Section II limits the Policy to research involving “known or potential risk to human health.” Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both. The final policy should apply the Section II threshold to transgenic animal research and include an exemption from the policy for the following with transgenic animals: Breeding, maintenance,

cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).

Define the coverage of recombinant and synthetic nucleic acid molecules. The draft policy defines scop primarily through biological agents and genetically modified cells, viruses and organisms and does not explicitly state how standalone rDNA molecules are treated. NIH should clarify if standalone nucleic acid molecules are intentionally outside the scope of this policy and if not, identify the circumstances under which they become covered.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Delegated review is a welcome modernization, but requiring every approval to be reported "in full" at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee's role after delegated approval should also be defined.

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish exemptions or administrative registration/reviews.

3. Continued utility of Risk Groups: Retain Risk Groups as a starting point, but do not rely solely on their use for oversight. Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations. Oversight categories and containment decisions
should rest on experiment-specific risk assessment and the BSL/ABSL framework.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No additional comments now

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes. NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents and clarify what information is necessary to achieve meaningful public transparency. NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes
6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Per Section III-B, IBC Functions:
"Minutes should be posted immediately after approval and once all appropriate and allowable redactions have been made."
In reflecting on (1) the time required to edit minutes, (2) the mechanics of posting on a public-facing webpage, and (3) holiday and staffing considerations, reasonable time should be afforded to IBCs to meet the posting requirement. We suggest an allowance to post within five to ten business days after a convened meeting.
Please clarify whether the IBC is confined to using the NIH-provided table in the IBC meeting minutes template, or whether the IBC may use a different format while publishing all required elements listed in the template.

6. Other feedback relevant to this resource: Additional clarification and inclusion of guidance, examples, or suggestions for institutional positions (e.g., Vice President for Research, Associate VP for Research Compliance, IBC Coordinator/Administrator) deemed suitable by NIH to fulfill the role of Authorized Organizational Representative (AOR).
Additional clarification regarding the role of the IBC in Section III-B would be helpful, particularly around expectations for "evaluating the expertise of personnel involved in research." What, if any, actions are expected of the IBC in response to the information supplied by the applicant?
Per Section III-B, Biological Safety Officer (BSO): The BSO's duties include, but are not limited to:

“Conducting periodic inspections to ensure that laboratory biocontainment facilities and equipment are functioning properly, biosafety standards are rigorously followed, and IBC approval conditions for the conduct of research are being followed.”
The term ensure appears to suggest that BSOs have enforcement authority, which is atypical of the role as conventionally understood. We suggest replacing ensure with language (e.g., assess, verify) that more accurately reflects the conventional consultative and advisory role of the BSO. We suggest that the BSO’s observations from such assessments be reported in accordance with institutional policies and procedures.
Draft policy retains the requirement for an institution to have a BSO if there is research at BSL-3 or higher. However, since the draft policy does expand the responsibilities of the BSO and the IBC, recommend that a BSO be identified for any institution with research at BSL-2 or higher.

Description: Comments on Draft NIH Biosafety Policy

277. Charles River Laboratories- Montreal/Senneville

I am responding: On behalf of an organization

Name: Alyson Guy

Name of Organization: Charles River Laboratories- Montreal/Senneville

Type of Organization: Other

Type of Organization - Other: Contract Research Organization

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Safety Toxicology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: One concern is the apparent scope of the policy. It is not clear whether the requirements apply only to NIH-supported activities or to all biohazard work conducted by an institution participating in NIH-funded research. If the latter, compliance could become very difficult, if not impossible, for some institutions. The policy should clearly define the intended scope and explicitly state whether requirements apply solely to NIH-funded activities or to all biohazard work performed by the institution. Consideration should also be given to the differing operational environments of universities versus private research organizations, which may operate under different confidentiality, proprietary information, and oversight frameworks.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Based on our interpretation of the draft policy, the majority of our work would likely fall under Section IV-3, requiring subgroup review and approval. We recommend NIH evaluate whether the proposed oversight structure is appropriately calibrated to risk and whether the volume of activities requiring higher levels of review may create unnecessary administrative burden without a commensurate biosafety benefit. Clear examples and guidance regarding activity categorization would be beneficial.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary adoption of the policy may be challenging for certain institutions, particularly private research organizations that operate under strict confidentiality and proprietary information requirements. NIH should consider providing flexibility for institutions that are not federally funded or otherwise subject to the policy, including alternative methods for demonstrating transparency and accountability without requiring public disclosure of sensitive institutional information.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We have significant concerns regarding the public posting requirements in the draft policy and associated templates. Section

III-A requires that IBC meeting minutes and incident reports be publicly posted for a minimum of five years. Section III-B further requires approved meeting minutes to be posted on a public-facing institutional website using the prescribed template. The draft meeting minutes template indicates that the names of IBC members and principal investigators may not be redacted. These requirements may be incompatible with institutional privacy expectations, confidentiality obligations, and security considerations. NIH should consider allowing greater flexibility regarding public disclosure, including the ability to redact personally identifiable information and sensitive operational details where appropriate.

6. Other feedback relevant to this resource: Additional implementation guidance is needed regarding IBC membership requirements. The requirement to include at least two unaffiliated community members may be difficult for some organizations to fulfill. Many institutions already experience significant challenges recruiting and retaining community members for other oversight committees such as IACUCs. NIH should consider alternative approaches or additional flexibility for institutions that cannot readily identify qualified community representatives.

Additional guidance would also be helpful regarding public posting requirements, confidentiality protections, and the applicability of the policy to private-sector research organizations.

278. Dr. Mark Peifer

I am responding: On behalf of myself

Name: Dr. Mark Peifer

Name of Organization: University of North Carolina at Chapel Hill

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Molecular and Cellular Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Defining transient expression via mRNA delivery as a form of "genetic modification" makes no sense, and would needlessly restrict fundamental research and preclincal applications. Genetic modification changes the genome in a heritable way, and that should be the definition.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

I am responding: On behalf of an organization

Name:

Name of Organization:

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed scope would benefit from greater precision to support consistent application across varied institutional settings. The final policy should define “research” and “biohazard” clearly and distinguish covered research from clinical diagnostics, public-health testing, assay verification and validation, routine analytical testing, product-support testing, and other activities that use biological materials without seeking generalizable knowledge. Terms such as “potential,” “acceptable,” and “significant risk” should be accompanied by objective criteria, a decision tree, and representative examples for academic, contract-research, analytical, and public-health settings.

Institutions also should be able to rely on reasonable, documented classification decisions made in good faith under then-current NIH criteria and examples, unless the decision was based on a material omission or is affected by new information or a material change in the work.

NIH should clarify the organizational boundaries of a covered institution, the meaning of research “sponsored by” an institution, and the treatment of affiliates, subsidiaries, separately incorporated locations, subrecipients, subcontractors, and client-sponsored activities. Potential oversight gaps involving recombinant plant and plant-pathogen research should be addressed through risk-based criteria developed in coordination with USDA or another appropriate federal agency.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered system is appropriate if federal oversight establishes clear minimum requirements while preserving local authority to apply project-specific judgment. Federal review or mandatory standards should focus on activities involving substantial hazards, novel agents, high uncertainty, or national-security implications. Institutions should be able to use documented administrative or delegated review for well-characterized, low-risk activities and reserve full IBC review for work whose hazards, uncertainty, or proposed controls warrant committee deliberation.

The final policy should identify the federal authority responsible for administering an expedited process for emerging, novel, or zoonotic agents when no current risk-group recommendation exists. That process

should include interim containment recommendations, defined submission requirements, points of contact, decision timelines, and time-limited emergency determinations so that appropriately qualified laboratories can perform urgent diagnostic, assay-development, and countermeasure work under defined minimum controls.

NIH should specify which project-review requirements are satisfied by equivalent federal oversight and which institution-level obligations—such as assurance, reporting, training, recordkeeping, and public posting—remain applicable.

3. Continued utility of Risk Groups: Risk Groups remain a useful baseline for understanding the intrinsic hazards of agents and should be preserved in an authoritative, publicly accessible federal resource. They should not, however, be treated as a stand-alone containment determination, particularly when an agent is genetically modified. Institutional risk assessment should consider whether a modification may alter host range, pathogenicity, transmissibility, environmental stability, treatment susceptibility, toxin production, or other relevant characteristics, and should select practices, equipment, and facility controls using the BMBL.

NIH has stated that implementation resources will draw from current Risk Group classifications and other existing guidance. The final policy should expressly preserve those resources until authoritative replacements are published, clarify the relationship between RG and BSL, maintain a searchable record of generally applicable determinations for previously reviewed experiment types, and confirm that existing approvals remain valid unless new information or a material change warrants reassessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary compliance is most likely when NIH offers practical tools and clear incentives rather
than extending mandatory requirements indirectly. Useful resources would include modular model policies, decision tools, training materials, sample risk assessments, and adaptable templates that institutions may adopt without becoming subject to unrelated funding requirements.

A tiered recognition or self-attestation program, confidential technical assistance, and access to the centralized incident-learning system would further encourage participation. NIH also should make clear how voluntary adoption affects an institution's legal and programmatic obligations, including that use of NIH tools or templates does not by itself create additional public-disclosure duties or implied certifications beyond the practices expressly adopted

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We support appropriate reporting and accountability for significant biosafety incidents and compliance failures. The templates should identify minimum data elements while allowing
institutions to use equivalent records and systems. The incident-learning function should encourage timely reporting, root-cause analysis, corrective action, and sector-wide learning, while preserving appropriate enforcement for willful misconduct, material nondisclosure, or repeated noncompliance.

The proposed National Biosafety Data and Safety Analysis Center could advance those objectives by aggregating, de-identifying, and analyzing incident and near-miss data. NIH should use that

centralized mechanism as the principal vehicle for public learning. Institutional reporting should support transparency, accountability, and corrective action, while institution-level public posting should be limited to information that can be disclosed without compromising privacy, security, legal obligations, proprietary information, or client confidentiality.

Although the draft contemplates allowable redactions, NIH should establish objective withholding and redaction standards so transparency obligations are applied consistently and do not inadvertently create safety, security, privacy, or legal risks. Institutions should not be required to publish information that could identify personnel or facilities, compromise physical security, cybersecurity, personnel safety, or appropriate access controls, disclose restricted or classified information, conflict with applicable legal or sponsor restrictions, interfere with an investigation, or expose proprietary research information. Public outputs should focus on aggregate trends, lessons learned, contributing factors, corrective actions, and other information that advances public understanding without increasing operational or security risk.

The meeting-minutes template should document attendance, quorum, recusals, risk determinations, required controls, votes, and action items without requiring sensitive protocol details to be reproduced in public-facing records. It should allow restricted information to be reviewed by an authorized subset or designated official and referenced in non-sensitive minutes. NIH should also clarify how public-posting requirements interact with the Federal Select Agent Program, classified and controlled information requirements, privacy obligations, contractual restrictions, law enforcement activities, and other applicable federal requirements.

6. Other feedback relevant to this resource: Additional implementation resources will be important to the clarity, consistency, and scalability of the future national framework. NIH should provide a scope decision tree; examples distinguishing research from diagnostics, validation, analytical, and product-support activities; risk-tiering and delegated-review criteria; an expedited pathway for emerging agents; and a maintained resource for
RG assignments and generally applicable determinations for previously reviewed experiments.

Guidance is also needed on institutional applicability, organizational boundaries, subawards and subcontracts, client-funded work, amendment thresholds, grandfathering, de novo renewals, review timelines, training documentation, institutional registration, PI and biosafety-official responsibilities, multi-site programs, and the relationship to Select Agent, USDA, biosecurity, classified, and other access-control requirements. The final policy should allow equivalent institutional systems and documentation when they satisfy the substantive requirements.

The draft proposes an effective date six months after publication of the final policy. NIH should consider whether that period is sufficient for institutions with large portfolios, multiple sites, or high volumes of short-duration projects, and whether a longer or phased implementation period with prioritized milestones would better support orderly implementation. Existing approvals should remain valid during transition unless new information or a material change warrants reassessment.

280. University of Washington

I am responding: On behalf of an organization

Name: Zara Llewellyn, PhD

Name of Organization: University of Washington

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical research, life sciences, molecular biology, genetics, immunology, oncology, infectious disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Full response is in the attached PDF.

Key Issues:

* Policy contradicts itself on RG1 organisms—states RG1 excluded but then requires review of genetically modified RG1 organisms

* "Biohazard" definition depends on undefined phrase "known or potential risk to human health" with no threshold

* Scope expands to non-NIH-funded research at NIH-funded institutions without clear boundaries

* Policy addresses RG2 agents, zoonotic agents, and environmental risk without coherent One Health framework or clarity on interagency jurisdiction (USDA, EPA, FDA)

* Expansion includes currently exempt Section III-F research (transgenic rodents, plasmids, genetically modified cells) without demonstrable safety benefit

Requested Actions:

* Exclude RG1 organisms unless genetic modification creates human health hazard

* Define "biohazard" with a credible risk threshold (not merely theoretical)

* Establish clear interagency jurisdiction framework

* Create exemptions or registration-only pathways for well-characterized, minimal-risk activities currently exempt

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Full response is in the attached PDF.

Key Issues:

* Policy lacks clear allocation of responsibilities: PI should own experiment-level risk assessment; IBC should approve agents/classes and set containment floors; NIH should review genuinely novel or high-consequence questions only

* "Material amendments" undefined—phrase "potential impact on biosafety assessment" is too vague to support consistent compliance

* Delegated review lacks operational clarity and flexibility for institutional variation

* No administrative-burden analysis; six-month implementation deadline is unrealistic

* Policy greatly expands IBC workload (wild-type RG2, genetically modified cells, primary cells, toxins, non-NIH-funded work, delegated review reporting, mandatory templates) without demonstrating federal capacity to handle NIH-level reviews

Requested Actions:

* Define clear PI/IBC/NIH roles and decision thresholds

* Define "material amendment" with examples of changes requiring vs. not requiring re-review

* Allow exemptions, notification categories, delegated review, and umbrella protocols for low-risk work

* Provide 24-month phased implementation with administrative-burden analysis

* Conduct federal capacity analysis for NIH review function

3. Continued utility of Risk Groups: Full response is in the attached PDF.

Key Issues:

* Many organisms lack RG classification; policy requires NIH approval for "emerging, novel, or zoonotic agents" without guidance on interim institutional determinations

* Risk assessment for genetically modified organisms needs guidance beyond RG classification

Requested Actions:

* Provide guidance for institutional classification of likely-RG1 organisms lacking published information

* Establish national Risk Group and containment-determination database; allow institutions to rely on NIH precedents

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The policy lacks mechanisms to encourage or support voluntary compliance at institutions not subject to the policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Full response is in the attached PDF.

Primary Issues:

* Prescriptive format conflicts with accessibility standards

* Duplicates content already in IBC applications, creating administrative burden without safety benefit

* Unclear which sections are mandatory vs. optional

* May inadvertently dictate how IBC meetings are conducted

Key Recommendations:

* Establish minimum content requirements only; allow institutional format flexibility

* Specify institutional capacity differences (600+ active protocols vs. small institutions need different approaches)

* Permit formats compliant with state digital accessibility laws

* Eliminate redundant sections; focus on decisions/discussions, not reproduction of application materials

* Clarify: Can institutions combine prior business and minute approvals? Must unapproved minutes be posted? Can minutes approval occur at the next regular meeting without special session?

DRAFT INCIDENT REPORTING TEMPLATE

Primary Issues:

* Public posting of incident reports with PI name and other information should not be required. Condensed summaries with de-identified information are suitable for public sharing.

* Template and policy language conflict on which incidents require public posting vs. federal reporting:

Do all incidents post publicly, or only those reported to NIH?

* Template format prescriptiveness conflicts with state accessibility requirements

Key Recommendations:

* Align incident reporting thresholds and definitions between policy and template

* Clearly specify which incidents require: federal 24-hour reporting / public posting / local management only

* Allow institutions to adapt template format while maintaining content requirements to meet state accessibility standards

* Define "appropriate and allowable redactions" with specificity

6. Other feedback relevant to this resource: Full response is in the attached PDF.

Core requirements are deferred to future supplemental materials, but institutions have only 6 months to bring new and ongoing research into compliance. A complete overhaul should not be finalized until operative guidance, templates, examples, decision rules, and implementation resources are available for public review as an integrated package.

Essential materials NIH should provide:
* Biosafety Assurance template with completion guidance

* Model institutional policies and decision trees

* Risk-assessment forms with worked examples covering modern virology and biotechnology

* IBC meeting-minutes and incident-reporting templates refined per feedback

* Training modules for IBC members, BSOs, PIs, and laboratory staff

* Sample completed minutes and incident reports

* Uniform redaction standards and guidance

* National Risk Group and containment determination database (searchable, with precedent guidance)

* Clear decision rules mapping current NIH Guidelines to new framework with examples

* Guidance on delegated review implementation

Administrative-Burden and Capacity Analysis: NIH has not published analysis of institutional workload

required or federal review capacity available.
Request:

* Conduct administrative-burden analysis before finalization

* Publish realistic estimate of institutional and federal workload

* Demonstrate federal capacity to handle increased NIH approval requests

Implementation Timeline and Phased Approach: 6 months is insufficient.
Request:
* Extend effective date to minimum 24 months after publication of all final materials

* Provide phased implementation with defined milestones:
1) Governance and assurance infrastructure (Months 1–6)

2) Higher-risk work transition (Months 7–12)

3) Mid-risk work transition (Months 13–18)

4) Lower-risk and legacy protocols (Months 19–24)

* Include provisional or deemed assurance mechanisms to prevent research interruption

Targeted Support for Smaller and Less-Resourced Institutions

Request:

* Provide dedicated biosafety supplements or cost-allowability provisions (not unfunded mandate)

* Develop workforce development programs and shared training resources

* Support flexible institutional models (shared IBCs, external services, consortium arrangements)

* Provide tools for mutual-aid arrangements in underserved regions

Binding Guidance and Interpretation Mechanisms

Request:

* Provide mechanism for institutions to obtain binding interpretations during implementation

* Establish clear precedent-setting process for published NIH determinations

* Create process for institutions to request waiver or variance from prescriptive requirements

Description: University of Washington Feedback on NIH Draft Biosafety Policy NOT-OD-26-112

ENVIRONMENTAL HEALTH & SAFETY
UNIVERSITY of WASHINGTON

October 16, 2026

NIH Office of Science Policy (OSP)
6705 Rockledge Drive, Suite 630
Bethesda, MD 20892

RE: NOT-OD-26-112

Dear NIH Office of Science Policy:

The University Washington (UW), through its Environmental Health and Safety Department (EH&S) and Institutional Biosafety Committee (IBC), submits these comments in response to the August 19, 2026, notice "NIH Releases Draft Biosafety Policy for Research Involving Biohazards for Public Comment," Notice NOT-OD-26-112.

The UW supports thoughtful biosafety regulation that promotes safe, responsible, and compliant research. The NIH draft Biosafety policy has significant implications for UW given the scale and breadth of our research enterprise and the more than $1.2 billion in federal research funding we receive annually. As a leading U.S. research university, UW has a strong interest in ensuring that the policy advances biosafety objectives while providing a clear and effective framework for institutional oversight of research involving biohazardous agents.

The UW supports the effort by the National Institutes of Health (NIH) to undergo a comprehensive review and evaluation of the NIH Guidelines, given the advances and changes in biomedical research and in the field of biosafety and biosecurity. The draft policy represents a substantial effort to modernize biosafety oversight for evolving research technologies and practices. However, as drafted, it cannot be implemented consistently or proportionately within a six-month timeframe. NIH should use the public comment period to substantially revise the policy, provide complete implementation resources, and reissue for broader stakeholder review before finalization.

The modifications requested in this comment will support NIH's stated goals of safe, proportionate, evidence-based, and consistent biosafety oversight while enabling institutional implementation that does not displace resources from higher-impact biosafety activities.

201 Hall Health Center, Box 354400, Seattle, WA 98195-4400

206.543.7262 | fax 206.543.3351 | www.ehs.washington.edu

HIGH LEVEL FEEDBACK ON THE DRAFT BIOSAFETY POLICY

1. **Scope Expansion Without Clear Boundaries:** The draft policy substantially expands IBC review requirements beyond the current NIH Guidelines but lacks sufficient clarity to enable consistent institutional implementation. Requirements for IBC review are expanded to include transgenic rodents, research with plasmids, cloning in lab strains of *E. coli* and yeast, and well-characterized cell lines of any species, research that is currently exempt (Section III-F) under existing NIH Guidelines. This expansion would redirect institutional biosafety resources and IBC capacity toward review of well-characterized, minimal-risk activities without demonstrable improvement in biosafety oversight or risk reduction.

   Request: Narrow and clarify the scope explicitly and ensure internal consistency. Establish clear criteria for when research must be reviewed versus when institutional processes or exemptions suffice. Exclude RG1 organisms unless genetic modifications demonstrably create a human health hazard.

2. **Administrative Burden Without Demonstrated Safety Benefit:** New requirements for IBC documentation, risk assessment, incident reporting, and public posting significantly increase administrative burden on biosafety professionals and IBC members without corresponding improvements in biosafety oversight or risk reduction. Biosafety time and resources are better invested in high-impact activities such as facility inspections, staff training, and incident investigation than in administrative compliance tasks and template reproduction. The additional transparency requirements are burdensome with little added safety value and potentially divert attention from higher-risk oversight.

   Request: Conduct and publish an administrative-burden analysis before finalization. Authorize proportionate mechanisms such as exemptions, notification-only categories or registrations, staff or biosafety officer review, and clear amendment thresholds.

3. **Unrealistic Implementation Timeline:** Six months is insufficient for institutions to inventory covered research; re-review existing research; revise internal policies and systems; train staff, IBC members, and researchers; and implement new processes.

   Request: Extend the effective date to at least 12 months with phased implementation up to 24 months after publication of final policy and complete

implementation resources. Provide phased milestones (e.g., governance and assurance infrastructure first; then higher-risk work; then lower-risk and legacy protocols).

4. **Critical Gaps in Definitions, Scope, and Guidance:** The policy employs key terms without defining them, contains contradictions between policy sections and templates, and lacks examples or decision criteria necessary for consistent implementation. Examples of undefined or contradictory terms include:

    - Risk Group 1 organism inclusion/exclusion ("genetically modified organisms" applied to RG1)
    - "Well-characterized cell lines" (species, criteria, genetic modifications)
    - Clinical research ambiguity
    - "Periodic" post-approval monitoring
    - Delegated review procedures and expectations

    Request: Provide precise, operationally useful definitions with decision criteria and worked examples.

5. **Lacks Modern Virology and Viral Vector Guidance:** The policy as written does not provide a framework adequate for assessing modern virology. It should include examples and criteria for replication competent and replication defective viruses, single-cycle viruses, viral vectors, pseudotyped particles, virus-like particles, replicons, and infectious clones. The current terms of the policy are not adequate to describe modern virology research.

    Request: Add a technically complete framework for viral vectors, replicons, helper systems, infectious clones, and clinical gene-delivery platforms with worked examples and risk-assessment criteria.

6. **Inflexible Template Requirements:** The proposed IBC minutes and incident reporting templates are prescriptive in format, duplicative of existing documentation, and do not accommodate institutional variation in size and operational model. Additionally, tables with text are unreadable by screen readers; if the template format is required to be a table, this template would not meet accessibility standards, which are required for documents posted on our public institution’s website.

Request: Establish minimum content requirements and allow institutional flexibility in format and structure. Permit institutions to adapt templates to state and federal accessibility obligations and operational workflows. Acknowledge that institutions managing 600+ active protocols require different documentation approaches than smaller institutions.

DETAILED FEEDBACK ON THE DRAFT BIOSAFETY POLICY

Section II.

Scope

- **Policy Definitions:** The UW recommends that broadening the applicability/scope of the policy should be based on scientific expertise and data. Before establishing definitions, NIH should assess the current landscape together with a panel of experts (after receiving comments). Specifically, definitions of biomedical research, biological agent, and novel agent or organisms are broad and inconsistent. In addition, the NIH's authority for biomedical research should not expand outside of the NIH's authority, which is limited to NIH-funded research.
- **Risk Group 1 organisms:** The policy as written is contradictory. It states that Risk Group (RG) 1 organisms are not included but genetically modified RG1 organisms are. Since human health hazards are the intended scope, RG1 organisms should not be included in the policy. An exception would be genetic modifications that cause a RG1 organism to become pathogenic or hazardous to human health. Removing RG1 organisms from the scope would also eliminate most standard cloning in lab strains of E. coli and yeast, which is similar to exempt experiments in the current NIH Guidelines.
- **Implementation timeline:** Six months for implementation is unrealistic for most institutions. Extend the effective date to at least 12 months and up to 24 months. Allow a phased implementation to provide updates to training, processes, application forms, resources, and to test new and adjust new programs.
- **Dual review/clearance when two sets of regulations apply**: "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." State clearly what the other regulations or purviews are and how this clearance would be obtained and if this research is also subject to the NIH Biosafety Policy.

General Definitions

- **Research clarification and scope:**
    - Clarify if "biomedical research" includes teaching laboratories and student organizations, where students conduct projects that may involve biohazards.
- **Research clarification and scope:** Clarify if "biomedical research, in laboratory settings" includes teaching laboratories and student organizations, where students conduct projects that may involve biohazards.
    - Clarify if clinical research in health care settings involving human blood, body fluids only, is out of scope of this policy.

Section III. Roles and Responsibilities

- **IBC and PI Risk Assessment Purview:** Preserve PI ownership of experiment-level risk assessment while defining proportionate IBC review roles. The IBC should not be required to separately document a risk assessment for each individual assay, procedural variant, or routine experiment of a PI's research.

Section III-B. Responsibilities of the Institutional Biosafety Committee (IBC)

IBC Functions

- **For IBC Meeting Minutes requirements:** Unapproved meeting minutes should not be required to be publicly posted. Confirm that meeting minutes are voted on at the next scheduled convened meeting and do not require additional meetings solely to vote on the prior minutes.
- **De novo reviews:** Clarify if a 3-year renewal application that is substantially the same as a new application meets the requirement for de novo review.
- **Post-approval monitoring:** The Policy states: "Periodically reviewing approved research conducted at the institution, to ensure compliance with the conditions established in the IBC approval and with the Policy. This responsibility may be delegated to the BSO or other staff, as appropriate." Provide a definition for "periodic" and the acceptable methods to achieve this. For example, are protocol amendments, renewals, or biosafety lab inspections adequate?
- **Provide definitions and examples related to incidents:**
    - Define "incident" and ensure it matches the description on the Incident Reporting Form.
    - Clarify if a "potential laboratory-acquired infection (LAI)" would include instances when post-exposure prophylaxis is routinely given.

  - Provide examples of BSL-3 equipment failures that require reporting. For example, is reporting a biosafety cabinet in alarm because of HVAC issues a reportable incident?
  - Provide examples of "inventory or security" issues with public health consequences.
  - Define "basic first aid."
  - Define a "compliance violation incident" that requires reporting. Does that mean a violation of this policy specifically (i.e., failure to obtain IBC approval prior to conducting work) or compliance beyond this policy?
  - Define "minor" and "low risk" spills. Does low-risk encompass BSL-1 and BSL-2? Clarify what characteristics of a spill would classify it as "minor" (e.g., volume, composition, location).

- **Public posting of incidents:** We are strongly against public posting of incidents without more redactions to remove identifying details. Required public posting of all biosafety incidents and near misses with the PI name will result in decreased reporting of incidents and will increase the collective biosafety risk to the research community. Including PI names, organism names, and identifying details of research does not contribute to incident metrics, patterns, and lessons learned.
- **Incident Reporting Thresholds:** Specify which categories of incidents require federal reporting within 24 hours, and which may be managed through local institutional procedures. Provide explicit definitions of reportable incidents, biosafety-related incidents, compliance violations, first-aid events, and minor spills to ensure consistent classification. We are strongly against public posting of incidents.
- **Reporting of lower risk, non-NIH reportable incidents:** The UW's stance is that non-NIH reportable incidents, and any incidents, should not be required to be posted on a public website. For non-reportable incidents, establish a proportionate documentation approach such as annual or semi-annual aggregate reporting rather than detailed written reports for each individual minor event, similar to annual OSHA logs. For non-reportable incidents, establish a proportionate documentation approach such as annual or semi-annual aggregate reporting rather than detailed written reports for each individual minor event, like annual OSHA logs. This approach would reduce administrative burden while maintaining records for audit and trend analysis and lessons learned.

- **Post-exposure prophylaxis:** NIH reportable incident includes "any incidents involving exposures at BSL-2/ABSL-2 that require agent-specific treatment beyond basic first aid." Does this include post-exposure prophylaxis treatment given before there is a suspected or confirmed lab acquired infection? For example, an occupational health response plan for Treponema pallidum calls for post-exposure prophylaxis treatment with specific antibiotics if an exposure occurs.

Section III-C. Responsibilities of the Principal Investigator (PI)

- **Training on the Policy:** For "coordinating and/or providing appropriate training on the Policy and biosafety requirements applicable to the research being conducted for all research personnel under their supervision": does the PI need to provide training on the Policy in addition to the institutional training? The institutional training on the Policy should be considered sufficient.
- **NBDSAC mention appears misplaced:** The paragraph about reporting to the NBDSAC is in Section III-C. PI Responsibilities. This should most likely be in the Institutional or IBC responsibilities section.

Section III-D. Responsibilities of the National Institutes of Health (NIH)

- **RG1 organism classification guidance:** Regarding the requirement for NIH approval for "research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL," how could this be applied to organisms that are likely RG1 but for which there is no published information? Provide specific guidance for institutions to classify RG1 microorganisms. Provide a description of RG1 organisms to exclude such organisms from requiring an institution to ask for NIH approval.
- **NIH Precedent and Reusability:** The policy anticipates publication of lower-containment determinations but does not state whether another institution may rely on them. Create a searchable national determinations and risk-classification database. Define when an institution may rely on published NIH containment determinations or containment-lowering decisions without seeking independent approval.

Section IV-1. Research That Requires NIH and IBC Approval Before Initiation

- **Clinical studies across multiple sites:** For clinical studies occurring at multiple sites, the UW recommends having provisions for reciprocity or shared reviews across the institutions where the study will take place.

Section IV-2. Research That Requires IBC Review and Approval Before Initiation

- **RG3 agents that can be used at lower biosafety levels:** Clarify if wildtype RG3 agents that can be used at a lower BSL per the BMBL still require IBC review before initiation or if delegated review is acceptable. Examples include wild type HIV and SIV.
- **Select Toxins:** Clarify if IBC review is required for Select Toxins even when the amount used is below the Federal Select Agent Program (FSAP) permissible limits.
- **Expansion of IBC review for currently exempt research:** The Policy states that "Research involving genetically modified cells, viruses, or organisms, other than plants (e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs)" requires IBC review and approval before initiation. This is an expansion of current requirements and includes research currently falling under Section III-F or exempt experiments that do not require IBC review. "Genetically modified cells" is too broad of a category, as many genetically modified cells currently fall under Section III-F and do not constitute a hazard, are low-risk, and do not warrant IBC review.
- **Clarify if RG 1 organisms are included in scope or not:** "Genetically modified organisms" would include modified RG1 microorganisms. This seems to contradict the policy scope that RG1 organisms are not included. Wild type and genetically modified RG1 organisms should be excluded unless the modifications cause the organism to become a human health hazard.
- **Cells with adventitious agents: "**Research with primary cells that may be contaminated by adventitious agents" requires IBC review and approval before initiation." This should only apply to adventitious agents that are human health hazards. And if the adventitious agents are wildtype, to be consistent with the Policy, only delegated review should be required. Cells with adventitious RG2 biological agents should be included in Section IV-3 for delegated IBC reviews for wildtype RG2 agents.
- **Clinical research scope:** The updated clinical research scope is more risk-based but is still not clear. "Capable of shedding, replicating, or integrating" is imprecise and may be interpreted inconsistently for study products such as genetically modified cells, non-replicating viral vectors, and oncolytic viruses. It is unclear if RG1 agents that can replicate or shed (e.g. wildtype bacteriophage that are not a human health hazard) are included in the scope.
- **Research That Requires IBC Review and Approval Before Initiation:** Lower risk research should be allowed to bypass IBC review. It should instead require specific protections to be implemented rather than be subject to case-by-case review. It

should instead require specific protections to be implemented rather than be subject to case-by-case review.

Section IV-3. Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members

- **Describe and clarify how delegated reviews work.** Allow institutions flexibility to determine how to use and implement delegated review specific to their research portfolio.
- **Wild type RG2 organisms:** Not all wild type RG2 organism research presents equivalent risks. Research with well-characterized RG2 organisms under standard conditions should not consume the same review resources as work involving enhanced resistance, aerosol generation, large scale, animal transmission, or altered host range. Allow delegated reviews for routine work and reserve full committee review for higher risk wild type RG2 research.
- **Modified RG1 organisms:** Do not include RG1 organisms in the policy scope if the intended focus is human health hazards.
- **Transgenic organisms** at BSL-1 include most transgenic rodents, which are currently exempt (Section III-F) and do not require IBC review. This expands required IBC delegated review to include transgenic rodents. This low-risk category of research should continue to be exempt, and including it within the scope of the IBC review creates a significant administrative burden, again without a safety benefit.
- **"Research with plasmids"** is very broad and most is currently exempt (Section III-F). This significantly expands IBC review, even if a delegated review, to include currently exempt research. Research with non-hazardous plasmids should not be included in the Policy scope. Instead, state specific instances when IBC review is warranted.
- **Hazardous nucleic acids** are not addressed by the Policy as written. Hazardous nucleic acids include infectious viral genomes, full-length infectious clones, and nucleic acids with delivery systems such as lipids or nanoparticles. These should be differentiated from low-risk plasmids and require IBC review and approval.
- **"Research with well-characterized cell lines"** is very broad and vague. The NIH needs to specify which species cells or cell lines, as many species of cell lines do not present a human health risk. Delegated IBC review should focus on species of cells that are potential human health hazards, such as human, non-human primate, bat, or species with zoonotic disease potential. Also, clarify if "well characterized cell lines" that are genetically modified would put them in the scope of both IV-2 and IV-3.

- **"Research with biological toxin proteins not on the Select Agent list."** Clarify if a "toxin protein" is different from a "toxin." Provide more specificity about which toxins require delegated IBC review and based on hazard, quantity, LD50, etc. If all toxins require review, this will significantly expand IBC review and approval.

Section V-E. Risk Mitigation Strategies and Laboratory Containment

- **Description of universal precautions for clinical research:** The policy states "that for clinical research in clinical settings, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection." The Policy should not include respiratory protection as part of "universal precautions." Requiring respiratory protection should be based on a risk assessment.
- **Biohazardous waste:** The Policy does not mention biohazardous waste. Is the BMBL the primary guidance for what items should be considered biohazardous waste and require treatment prior to disposal? The NIH should define what is biohazardous waste and provide guidance for methods of disposal.

Other questions that are not included in the current sections

- **Risk Group appendices:** The draft Policy does not include appendices or lists with RGs for organisms. The NIH should publish appendices of Risk Group 2, 3 and 4 organisms in the final Policy.

DRAFT REQUIRED IBC MEETING MINUTES TEMPLATE

Allow flexibility in IBC minutes format and detail level to accommodate varying operational models. Rather than mandating the use of a template or a specific table format, establish minimum content requirements and permit institutions to adapt templates to their state and federal accessibility obligations and operational workflows. With new federal accessibility standards, templates will need to be formatted for compliance. Acknowledge that institutions managing 600+ active protocols will require different documentation approaches than smaller institutions.

Primary concerns:

- **Clarity needed on template flexibility and format:** Template flexibility is undefined. State which sections are mandatory or optional, if the format can be adapted, and what level of detail is required. Institutions need flexibility to format the document to their needs while still meeting the minimum requirements.
- **Excessive duplication**: Multiple sections require information already documented in IBC applications and review materials, creating administrative work that diverts resources from meaningful biosafety activities, such as lab inspections and training.

- **Accessibility compliance risk**: The current table format may not meet Washington State digital accessibility standards for posting on our public institutional website. Allow flexible options for, so we request flexibility in document layout and formatting to ensure compliance with state digital accessibility standards
- **Meeting process prescriptiveness**: The template may inadvertently dictate how IBC meetings are structured and run, rather than serving as a documentation tool. Institutions should be allowed flexibility to order and organize the sections to mirror how their IBC meetings operate.
- **Section organization**: Some sections are redundant, misplaced, or lack clear purpose relative to biosafety oversight. Again, provide more clarity around minimum requirements, organization, and allow for flexibility.

DETAILED FEEDBACK ON IBC MEETING MINUTES TEMPLATE:

- **Template Flexibility and Format:** It is unclear whether institutions must use the template exactly as provided or whether format adaptations are permissible. Clarify minimum documentation requirements and allow institutions to adapt format and structure to comply with state accessibility laws and operational needs.
- **Other Individuals in Attendance:** The purpose of documenting others in attendance is unclear and creates an administrative burden. We support removing this as a required section. If documentation of external participants is needed, include only speakers invited to discuss specific projects (e.g., PIs answering protocol questions), and document within the project discussion section.
- **Registration Number:** Including the registration number adds detail that does not enhance biosafety documentation. Project type (i.e., new, renewal, amendment) is more operationally useful. Replace registration number with project status indicator (new, renewal, change/amendment).
- **Project Overview:** Current template requires essentially the entire IBC application to be reproduced in the minutes. Our main concerns include:
    - Requires extensive duplication of information from application and review documents
    - Creates significant administrative burden that diverts time from lab inspections, training, and direct biosafety work
    - Details in this section are repeated later in the BSL Assignment section

  Replace with a high-level summary that includes only operationally relevant information that documents the essential biosafety elements reviewed without duplicating the full application:

    - Agents or organisms being used, including description of genetic modifications

  - General description of laboratory activities and procedures
  - Containment level(s) assigned
  - Special factors affecting containment or safety (e.g., oncogenic inserts, unique equipment, antibiotic resistance markers)
  - Any novel procedures or specialized techniques

- **Readout of Projects Approved by Delegated Review:** Placement in the middle of individual project review is confusing. Delegated approvals should be presented as a separate batch item, not interspersed with full committee reviews, or at least have the option to be a separate item. Our concerns include:
  - Current placement disrupts logical flow of meeting minutes
  - Unclear what level of detail should be documented for delegated reviews compared to full committee reviews, as delegated reviews typically require minimal documentation

  Allow institutions to have a dedicated “delegated reviews” section before or after individual project reviews. Allow documentation of delegated approvals in a simplified format (e.g., list with PI, agent, status [new/renewal/change]) as compiled report, rather than in the same detailed format required for full committee reviews.

- **Risk Assessment and Discussion:** The current template requires listing all activities, equipment, and procedural details, which is information already included in the IBC application. This creates duplicate documentation burden without adding value to the meeting minutes. Instead, consolidate into the Project Overview section. Document discussion notes and IBC concerns or recommendations rather than restating application content.
- **Training:** The template appears to require listing lab-specific training for every project reviewed. If required, this adds documentation burden without biosafety benefit to describe in excessive details of training that are not typically discussed during IBC meetings. At our institution, lab-specific training needs are addressed as part of the biosafety lab inspection. We support documenting the institutional biosafety training status of the PI only. Remove the requirement to include lab-specific training details unless there are unique training requirements from the IBC as part of the risk assessment or training deficiencies discovered during the biosafety lab inspection.
- **Occupational Health Representative Review:** At our institution, occupational health requirements are typically communicated to the IBC through the Biosafety Officer, who coordinates with the occupational health team. We support renaming as "Occupational Health Considerations" and make the section to be used “when applicable” when occupational health issues require specific committee discussion. Allow the IBC

reviewer or BSO to note occupational health requirements without requiring separate presentation by a representative.

- **Biosafety Level (BSL) Assignment:** BSL is discussed in the Project Overview section; repeating it as a separate section creates redundancy. If retained as a separate section, the placement is unclear, and BSL assignment is not applicable to clinical trials. If retained, place immediately after Project Overview. Alternatively, consolidate into the Project Overview section and remove duplication. Clarify that this section does not apply to clinical trial research.
- **Review of Incidents:** Clarify which incidents require review at a convened IBC meeting, such as NIH-reportable or all biosafety incidents, and what details should be included in the minutes.
- **Inspections / Ongoing Oversight:** At our institution, biosafety lab inspections are synchronized with the project reviews, so it makes logical sense to include the biosafety lab inspection update with the Project Description. Allow institutions flexibility in how they report biosafety lab inspection findings based on how they operate.
- **IBC Training:** We recommend having this as an optional section to use when applicable, as IBC training may not be provided at every convened meeting.
- **Public Comments:** We recommend having this as an optional section to use when applicable, as IBC meetings are not required to be open to the public.

DRAFT REQUIRED INCIDENT REPORTING TEMPLATE

- **Clarify which incidents require reporting to NIH:** The incident reporting template contains background information and reporting thresholds that differ from the policy language, creating confusion about which incidents trigger NIH reporting obligations. The policy bases reporting requirements on biosafety levels, while the template expands beyond these thresholds without corresponding biosafety level specification. Align reporting requirements and thresholds between the policy and template and specify the role of biosafety level determinations in triggering federal reporting obligations. Recommend that low risk incidents be exempt from report, e.g. incidents involving RG 1 organisms.
- **Clarify which incidents are required to be posted publicly:** Clarify whether all incidents must be posted publicly or only those incidents required to be reported to NIH. The template and policy language appear contradictory on this point. Clearly specify which incidents are subject to mandatory public posting and provide corresponding guidance on redaction standards and timelines.

- **The UW's stance is that public posting of incident reports should not be required.** The details included in the template can potentially compromise identity and privacy and can result in less reporting of incidents for fear of information being made public. The IBC meetings and minutes will already reflect a discussion of incidents.
- **It is unclear if the incident reporting template's layout and format are prescriptive requirements** or whether institutions may adapt the template format to accommodate minimum content requirements while ensuring compliance with applicable state digital accessibility laws. Allow flexibility so that institutions can fulfill reporting obligations while meeting state-mandated accessibility standards for publicly posted materials.

Thank you for the opportunity to provide feedback on these important considerations for oversight of biological research.

Sincerely,

Institutional Biosafety Committee (IBC)
University of Washington

Environmental Health and Safety Department (EH&S)

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Kennesaw State University

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: • The scope statement that this policy covers "cells, viruses, or organisms, other than plants, that have been genetically modified" introduces extremely broad oversight without a proportional increase in biosafety protection. As written, this would include materials such as:
o Reporter cell lines
o Stable knockout cell lines
o Common transgenic mouse strains already used at ABSL-1, which pose no additional risk than using a wild-type mouse strain
o Common drosophila and Arabidopsis strains already used at BL-1/ACL-1, which pose no additional risk than using a wild-type drosophila or Arabidopsis strain
o Replication-incompetent vectors expressing low-risk transgenes
o Commercially available genetically modified research models
As written, nearly every biomedical research institution would have hundreds or thousands of protocols captured by this policy. While the delegated review category may reduce the burden associated with ongoing review, the initial registration burden remains substantial. IBCs may become overwhelmed reviewing large numbers of low-risk projects that do not present materially different biosafety risks from currently exempt work.
Recommendation: Consider excluding well-characterized genetically modified cell lines incapable of producing infectious agents and posing no greater risk than the parental cell line. Additional exclusions or streamlined pathways should be considered for low-risk genetically modified systems.

• The regulated community would benefit from additional clarification regarding:
o Agricultural and veterinary pathogens
o Plant pathogens
o Clinical research activities
o Environmental and field research
o Arthropod research programs
The boundaries of policy applicability to these areas are not always clear.

• Six months is not sufficient time to implement a policy of this magnitude.
o Implementation will require:
o Revision of institutional biosafety programs
o Revision of IBC applications and registration systems
o Development of new review procedures
o Training of IBC members and biosafety personnel
o Training of investigators and laboratory staff
o Registration of currently unregistered activities
o Review and approval of large numbers of new protocols
Many institutions have substantial portfolios of research that have never previously required IBC review.
Recommendation: Provide at least a 24-month implementation period following publication of the final policy.

Definitions and terminology
• The term "biohazard" is used throughout the policy yet is not formally defined. This creates uncertainty because traditional biosafety programs commonly consider the following to be biohazards:
o Human pathogens
o Animal pathogens
o Plant pathogens
o Biologically-derived toxins
o Recombinant materials
o Human-derived tissues and materials
The absence of a formal definition creates ambiguity regarding the actual scope of the policy.

• The definition of biomedical research references research that falls "within the mission of NIH." This definition will be difficult if not impossible to apply consistently, and leads to the following unanswered questions:
o Who determines whether a research topic falls within the NIH mission?
o What criteria should institutions use?
o How should disagreements be resolved?
A more operational definition should be considered.

• The current definition limits biological agents to bacteria, viruses, fungi, or parasites that cause human disease. However, the policy later addresses:
o Emerging agents
o Novel agents
o Zoonotic agents
o Genetically modified agents
o Prions
o Self-aggregating proteins
The policy should reconcile these concepts so that the definition aligns with the materials actually regulated by the policy.

• The acronym GDMO is used extensively but is not formally defined. A formal definition should be included. Additionally, the policy should further address:
o Gene drive insects
o Gene drive microorganisms
o Attenuated systems
o Non-pathogenic laboratory systems
The current requirement that all GDMO research be conducted at a minimum of BSL-2 appears inconsistent with the policy's broader risk-based framework and with longstanding biosafety principles that containment should be determined through risk assessment rather than solely by the presence of a genetic modification. For example:
o Many attenuated systems present lower risks than wild-type RG2 organisms.
o Certain laboratory insect systems require containment strategies fundamentally different from traditional BSL-2 laboratory design.
Recommendation: Allow BSL designation to remain driven by risk assessment rather than requiring BSL-2 for all GDMOs.

• The current definition restricts toxins to proteins or peptides produced by living organisms. Many biologically derived toxins do not fit this definition.
Recommendation: Align the definition with established Select Agent terminology and existing federal frameworks.

• The policy does not formally define field research. However, the policy repeatedly references:
o Environmental release
o Ecological assessment
o Environmental containment
If field research is intended to fall within the scope of the policy, it should be explicitly defined and addressed within the scope section.

• The policy should include additional definitions on the following types of genetic changes, and where they lie within the scope of this policy.
o Genetic engineering
o Modification resulting from passaging cells
o Modification resulting from reassortment
o Modification resulting from chemical exposure
o Modification resulting from radiological exposure
o Reverse genetics
o CRISPR-Cas9
o Gene knockouts
o Using small RNAs for functions like silencing genes
o Other commonly used molecular biology techniques

• The following terms used within this policy should also be formally defined and reconciled throughout the policy:
o Biohazard

o Biocontainment
o Biosafety
o Biosecurity
o Incident/Near miss
o Notes: Requiring reporting of “any incident” at BSL-3 or BSL-4 could generate large numbers of notifications for events that pose little meaningful risk. In addition, no provision for confirming the legitimacy of an incident is included, and the timeline for reporting is not defined. Note that at my institution, incidents are reported through an online internal system, after which they are routed through one person to assign the incident for review to the correct personnel – incidents involving biological materials are sent to myself as the BSO or one of my direct reports for investigation; however, if the individual who routes the incidents for review is out of office, the institution may technically have been notified, but my group will not have known about it to report it to NIH, nor would we have had time to internally verify the scope and occurrence of the incident. Further, I am notified via E-mail of incidents assigned to me – which essentially means that over the weekend and when I am on vacation, I may not become aware of an incident right away.
o Recommendation: Provide objective reporting thresholds and decision criteria to promote consistency among institutions. Allow institutions to internally confirm the scope and occurrence of the incident prior to making the report to NIH. Clarify the timeline for reporting to take into account different the different reporting types that may come in (E-mail, or routed to different personnel before it gets to the BSO/designee). Please also stratify the reporting timelines based on risk – lower risk events and administrative non-compliance should allow a longer time to report. Additional examples of reportable incidents within the implementation guidance would be valuable.
o Release/ Environmental release/Loss of containment
o Laboratory-acquired infection
o Delegated review
o Containment reduction/Lowered containment
o Approval
o Significant risk/Significant risk to human health
o Potential community risk
o Public posting

• At my institution, the PI does not have all the power to meet the responsibilities listed in this policy, such as:
o Selection of facilities (assigned by the department to the PI)
o Ensuring integrity and maintenance of facilities (performed by facilities maintenance)
o Ensuring integrity of physical containment equipment (performed by EHS)
Please revise the responsibilities section to more broadly allow these functions to be performed by other groups, subject to the makeup of the institution.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): • Section IV-1 proposes NIH review and approval for research involving emerging, novel, or zoonotic agents for which classification or containment recommendations are unavailable in the BMBL. This creates significant practical concerns, as the BMBL contains only a limited subset of organisms encountered in research. At several institutions where I have worked, numerous characterized organisms were routinely utilized that do not appear in the BMBL. As written, the proposal may unintentionally require NIH review for a very

large volume of relatively low-risk work, and this indicates that work will have to stop while NIH reviews work already being safely performed at our institutions. Potential consequences include:
o Delays in protocol approval
o Increased administrative burden
o Bottlenecks at NIH
o Slowed research progress
A risk-based framework must allow institutions and IBCs authority to perform containment determinations for lower-risk agents without halting research for NIH to review proposals. It would be helpful for NIH to update this section to state that they will perform an initial assessment of risk group with a stated expedited turnaround time so that institutions can perform the risk assessments and assign the appropriate BSL for the work at hand.

• The policy creates multiple pathways requiring NIH review, including:
o Novel agents
o Emerging agents
o Zoonotic agents without existing classifications
o Requests to lower containment
However, the policy establishes no review timelines. Institutions need predictable review processes to support grant timelines, hiring, procurement, and project planning.
Recommendation: NIH should establish target review timelines and communicate expected turnaround standards.

• The proposal assumes NIH has sufficient capacity to review potentially large numbers of novel organisms, containment reduction requests, petitions, and classification inquiries. Institutions would benefit from greater transparency regarding anticipated staffing models, expected review volume, prioritization criteria, and contingency plans should submitted requests exceed available review capacity.

• NIH determinations regarding containment levels may have significant impacts on cost, facilities requirements, and project feasibility. The policy should include:
o An appeal process
o A mechanism for reconsideration
o A dispute-resolution pathway
Without such provisions, institutions may have no recourse if they believe a containment determination is unsupported by available science.

• The draft requires appointment of a Biological Safety Officer (BSO) when institutions conduct:
o BSL-3 research
o BSL-4 research
o Research involving GDMOs
However, later language provides that another institutional official may perform these responsibilities if a BSO is not designated. These provisions appear inconsistent. In addition, there is no provision for when a BSO is on vacation or sick.
Recommendation: Include a BSO on the IBC in all cases, not just in higher-risk scenarios. Biosafety

officers provide fundamental expertise in performing protocol review, incident investigation and response, containment determinations, and risk assessments of all research with biological materials at their organization (irrespective of biosafety level, risk group, genetically modified or wild-type status, etc.). Removing BSOs from the IBC unless there is a higher risk portfolio of work at the institution will open up significant gaps in protocol review and risk assessment. Please provide language allowing a BSO to designate another individual in his/her place.

• The policy substantially expands IBC responsibilities, including:
o Protocol review
o Incident review
o Public posting requirements
o NIH petitions
o Continuing oversight activities
For institutions with active research portfolios, this expansion could significantly increase committee workload.
Recommendation: NIH should provide greater flexibility for administrative review, delegated review, and biosafety office functions for lower-risk activities. Additional guidance on effective use of delegated review authority would improve implementation.

• Delegated member review: The policy includes a delegated member review, which is helpful. However, requiring that the approval must be reported in full to the IBC at its next scheduling meeting presents a large burden, and will significantly lengthen IBC meetings and administrative burden for inclusion on the IBC minutes. Please include the provision that the approved protocols which underwent a DMR can be included as a published list within the IBC meeting agenda, rather than discussed in individual detail in the meeting, and that the same list will be published within the minutes. This can be a simplified table including the following fields:
o Protocol number
o Protocol title
o PI
o Agents
o Approved biosafety level

3. Continued utility of Risk Groups: • The draft appropriately emphasizes evaluation of synthetic biology research and constructs generated from multiple sequence sources. However, reliance on the highest Risk Group classification of source organisms may unintentionally result in overly conservative classification when small, nonfunctional, or biologically insignificant genetic elements are incorporated into otherwise low-risk systems.
Recommendation: Emphasize the functional contribution of inserted sequences and resulting phenotype rather than assigning disproportionate weight to the Risk Group designation of the source organism.

• I believe that biosafety levels are still helpful for this field, and align with NIH in their stance that BSLs must be designated based on the actual risk and not solely on the risk group of the base organism. While risk groups give a good starting point, using biosafety levels to help break up different facility design, practices, and procedures into different groupings remains useful for the regulated community. Please retain the utility of risk groups, and allow institutions to continue performing risk assessments, taking

into consideration the characteristics of the biohazard, manipulations of the biohazard, and genetic modifications when assigning a biosafety level. I believe it will be most helpful for NIH to allow its policy to align with the BMBL for the definitions of biosafety levels, and to align with other documents helpful for facility design and assignment of controls (such as the Arthropod Containment Guidelines, and Practical Guide to Containment: Plant Biosafety in Research Greenhouses). If NIH does not wish to rely on sources such as these, NIH should publish within this policy definitions of containment levels it wishes the regulated community to adhere to, including provisions for insect, large animal, and plant work.

• There are several types of research which are so low-risk that IBC review does not actually provide a gain in the field of biosafety. This type of work includes:
o Commercial transgenic animals maintained at ABSL-1
o Low-risk plasmids
o Replication-incompetent non-integrating vectors expressing low-risk transgenes
o Well-characterized cell lines
o Genetically modified RG1 organisms
• These materials should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I did not specifically have comments on this.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: • The proposal would require public posting of:
o IBC meeting minutes
o Incident reports
o Continuously updated committee rosters
o Biosafety program information
I support transparency and public trust. However, implementation of these requirements will create challenges related to:
o Security-sensitive information
o Proprietary research
o Confidential commercial information
o Identification of research personnel
o Dual-use concerns
o Targeting of research personnel
o Protection of laboratory infrastructure details
In addition, preparation of documents for posting will likely require substantial administrative effort to ensure appropriate redactions, without additional support mandated for the offices which will hold this responsibility.
Recommendation: NIH should consider requiring publicly available summaries/tables rather than full meeting minutes and incident reports. Standardized public summaries would promote transparency while reducing the risk of disclosing sensitive information and minimizing administrative burden. Redaction rules must be clearly defined to allow for removal of proprietary and security-sensitive

information.

• Public disclosure will also have another negative impact: This will impede institutions' safety culture, as the template incident report names the principal investigator. This will lead to:
o Decreased privacy for affected individual(s) within small research laboratories, as individuals seeking information will be able to look up the research lab, find the members, and narrow down the possible person who was involved in the incident.
o A "hide the incident" attitude, where, as a result of the bullet above, researchers will not report incidents to the IBC so that their lab is not publicly mentioned in an incident log.
o Inadvertent non-compliance with medical information disclosure.
Please revise the incident template to remove the items to be publicly posted which can lead to a researcher being identified and targeted, including:
o Principal investigator name
o Grant number
Detailed records can be submitted to NIH for oversight, but should not be publicly posted.

• Use of the incident templates, when each institution already has its own means of performing incident investigations, will pose a substantial administrative burden while affected institutions are not given additional resources to cover those additional burdens. Please allow institutions to use their own incident reports (redacting and adding information as needed) to cover this requirement, or include a provision under this policy that additional support for the biosafety office/IBC will be provided to meet the additional administrative burden.

• The policy references record retention requirements under federal grant regulations while simultaneously requiring public posting of certain records for designated periods. Because incident reports may involve multiple protocols, multiple grants, and differing retention schedules, institutions will face uncertainty regarding retention obligations.
Recommendation: Provide a single, harmonized retention framework applicable to biosafety records generated under this policy.

6. Other feedback relevant to this resource: • Additional resources requested:
o Implementation guidance should include decision trees and flow charts for determining containment levels.
o Implementation guidance should include a decision tree for determining whether work is within the scope of the policy.
o Implementation guidance should include a decision tree for when a protocol must go to NIH, vs. go to the IBC, vs. DMR, vs. exempt. This may be combined with the decision tree allowing users to determine whether their work is in the scope of the policy.
• NIH should provide on an annual basis:
o Aggregated reports by region, institution, and biosafety level
o Lessons learned from incidents
o Leading indicators of biosafety
• NIH should continually provide its set precedents – for instance, publicly posting a searchable database which shows risk groups of organisms NIH has set the risk group for, deviations, and whether the prior decision applies to future research at other institutions or for other PIs.

• In the comments above, I have highlighted several areas which will cause an enormous increase in administrative burden. This burden will be held by groups which from my experience are often understaffed and already overburdened without this new policy. A formal regulatory impact assessment should be conducted to estimate institutional costs associated with implementation. Please consider the financial impact of this policy change, and consider dedicated funding supplements and personnel hiring. Many biosafety programs already operate with limited staffing resources, and this policy will significantly increase demands on already constrained biosafety resources. This model will lead to burnout, lack of compliance, and eventual risks to funding.

Uploaded File: NIH-Draft-Biohazard-Policy-Comments.docx

Response to NIH Request for Comment on Draft NIH Biosafety Policy for Research Involving Biohazards (Notice: NOT-OD-26-112)

1. **Policy Scope:** The policy promotes a risk-based approach rather than a list-based approach, but the definition of what constitutes research with biohazards is excessively broad. Provided examples of biohazards encompass biological entities that are generally not considered to be biohazardous (for example, replicative human cells administered to research participants and self-aggregating proteins such as microtubules).

   Recommendation: Additional scope about what biological material is, or is not, subject to the policy, with examples should be provided.

2. **Required review of historically exempt research:** The stated goal of removing red tape for low-risk research conflicts with expanded review of historically exempt research. The policy does not demonstrate a reduction in administrative burden for low-risk research involving well-characterized laboratory strains (genetically modified RG1 biological agents) and established transgenic animals at ABSL-1. This is currently exempt from the NIH guidelines and represents a huge portfolio of institutional research. Delegated review is presented as streamlining, yet it creates mandatory full reporting, IBC minutes documentation and approval, and public posting.

   Recommendation: Research that is exempt from IBC review under the NIH guidelines should remain exempt in the new policy.

3. **Required review of low-risk research:** The policy requires clarification as to whether replicating cellular therapies in humans are exempt from IBC review. As written, the policy requires IBC review of clinical research involving administration to human research participants of products that are capable of shedding, replicating, or integrating. Replicating cellular therapies include CAR-T cells, a therapy platform that is widely approved by the FDA. CAR-T cells are created by transduction with lentiviral vectors, typically by the sponsor of the clinical trial. Once the transgene is integrated these cells pose little infectious risk.

   Recommendation: Cellular therapies such as CAR-T cells that are created by the clinical trial sponsor outside of the institution performing the trial should be exempt from IBC review under the new policy.

4. **Duplicative reviews; gain of function:** The policy duplicates oversight that will be required by the U.S. Government Policy for Stopping High-Risk Life Sciences Research. The policy requires review of gain of function research that is both recombinant and non-recombinant by an IBC. The U.S. Government Policy for Stopping High-Risk Life Sciences Research also requires reviews of research that meets the definition of dangerous, or potentially dangerous, gain of function research by an IRE.

   Recommendation: The two policies should cross reference one another and provide an integrated framework for compliance.

5. **Duplicative reviews; adventitious agents:** The policy duplicates oversight currently required by the OSHA bloodborne pathogen standard. The policy requires IBC review of research with primary

cells that may be contaminated by adventitious agents. Adventitious agents found in human body fluids and tissues are already regulated by the OSHA bloodborne pathogen standard and its interpretations.

Recommendation: Adventitious agents found in human body fluids and tissues should be exempted from oversight under the policy.

6. **Retroactive reviews:** The policy requires clarification regarding retroactive review of already approved IBC registrations.

   Recommendation: Currently approved protocols should be grandfathered, until renewal, a period not to exceed three years. This is consistent with the three-year IBC approvals outlined in the policy.

7. **Security of Select Agent research:** The policy requires clarification about whether federal select agent program (FSAP) research information should be made available to the public. Much select agent research is conducted in BSL-3 labs. The policy requires publicly-posted information regarding whether the institution conducts research in a BSL-3/ABSL-3 facility. Public disclosure of such research information could present both institutional and national security risks.

   Recommendation: The policy should require IBC review of select agent research but exempt it from public disclosure through redaction of IBC minutes.

8. **Medical privacy concerns:** Public disclosure of incident information could result in compromised medical privacy, and reduced willingness to report incidents. The policy requires posting all incident reports that are both reportable and not reportable to NIH on a public-facing webpage, using the required incident reporting template. This template includes (1) the name of the Principal Investigator, (2) the research materials involved in the incident including full agent name, and description of strain or construct, (3) injury or illness associated with the incident and (4) medical treatment provided. While the policy claims to protect the identify of individuals involved in incidents by not requiring them to be named, it is a straightforward exercise for the public to connect the dots and link the PI name to the people in the lab, especially since labs typically comprise a few individuals and Principal Investigator lab websites frequently name the personnel and their research focus, including the materials they work with. This type of query can be accomplished on a grand scale using AI tools. Given the potential loss of medical privacy, researchers will be less likely to report accidents, which increases the risk of untreated injuries and exposures to hazardous materials.

   Recommendation: The policy should preserve reporting of applicable incidents to NIH but these should not also be required to be publicly posted by the institutions. NIH should make incident reports available to the public but should redact information identifying reporting institutions and PI names to protect medical privacy.

9. **Compromised researcher and animal safety:** The policy requires any incident involving research subject to the policy with an animal that is housed at BSL-1/ABSL-1 containment and above (e.g., bite, scratch, escape or improper disposition) to be posted on a public-facing webpage, using the

required incident reporting template, regardless of whether biohazards were involved. The template includes (1) the name of the Principal Investigator, (2) information on animal species, and (3) the animal procedures being performed at the time of the incident. While institutions such as mine adhere to the highest level of animal welfare requirements, public reports of incidents in animal facilities compromise researcher and animal safety because they can be exploited by animal rights activists. It is a straightforward exercise for animal rights activists to connect the dots as above and identify individuals who are allegedly committing animal abuse. This type of querying can be accomplished on a grand scale using AI tools.

Recommendation: The policy should not require public posting of incidents involving animals. Incident reports involving biohazards should be reported to NIH. Incidents that do not involve biohazards should not require reporting to NIH. NIH should make incident reports available to the public but should redact information identifying reporting institutions and PI names to protect researcher and animal safety.

10. **Resource concerns:** The proposed policy is an unfunded and unsupported mandate. The policy substantially expands institutional responsibilities for IBC oversight, documentation, training, incident review, public reporting, record retention, and oversight of research that may not itself receive NIH funding. We have assessed the administrative and resource impact of the policy and conclude this imposes a significant additional burden on IBC members and will require hiring of additional administrative staff.

    Recommendation: NIH fully fund any such associated indirect costs. NIH should further help institutions to comply by providing comprehensive implementation materials, model procedures, templates, training, and technical assistance.

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Virology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support replacing the NIH Guidelines with risk-based biosafety oversight, and I write in support of that objective. My comments identify where the draft Policy does not yet achieve it.

1.1 The draft expands oversight of research NIH has already determined to be low risk, without explaining what changed.

NIH has described this effort as expanding oversight at the high-risk end while reducing burden for low-risk research. The second half has not been achieved. The draft brings within its scope several categories of research that are currently exempt under the NIH Guidelines because the NIH Director affirmatively determined that they do not present a significant risk to health or the environment.

- Propagation of recombinant plasmids in Escherichia coli K-12 host-vector systems, exempt under Appendix C-II where the host carries no conjugation-proficient plasmid or generalized transducing phage and the insert derives from neither an RG3/RG4 or restricted agent nor a potent toxin. Under Section IV-3 the same work becomes "research with genetically modified RG1 biological agents" and requires approval before initiation.
- Transfection of such a construct into a cultured mammalian cell line, exempt since 59 FR 34472 (July 5, 1994) for recombinant molecules containing less than one-half of a eukaryotic viral genome propagated and maintained in tissue culture. Under the draft this is a genetically modified cell, which appears in Section IV-2 as full-committee work and, as a well-characterized cell line or a plasmid expressing a low-risk transgene, also in Section IV-3 as delegable. The Policy states no precedence rule, so institutions cannot determine which tier applies.
- Breeding, transfer and use of BL1 transgenic rodents, exempt under Appendices C-VII and C-VIII. In adopting the breeding exemption at 76 FR 3150 (January 19, 2011), NIH concluded that these experiments "do not pose an appreciable risk to human health or to the environment" and that "the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk."

Generation of such lines is addressed under Section III-E-3, requiring registration at initiation but not prior approval. Section IV-3 would require prior approval for all of it.
- Certain research with RG1 agents not involving sequences from RG3, RG4 or restricted organisms, exempt under Appendices C-II through C-V.

The first two categories deserve particular attention because they are not marginal cases. Construction of expression plasmids and their introduction into cultured cells are the most frequently performed experimental activities in molecular biology and virology laboratories; a single project may generate dozens of constructs in a year. The draft does not state what must be registered — the backbone alone, the backbone with each insert, or each insert with each point mutation — and the answer determines whether this is an annual formality or a continuous bottleneck. Approvals also expire at three years and require de novo submission, so the burden recurs.

The draft offers no revised risk assessment for any of these categories. The cumulative-burden concern NIH identified in 2011 applies with greater force today, and with substantially greater force to routine cloning and transfection than to the rodent breeding it was written about. I ask that NIH either preserve these exemptions expressly or state what evidence supports a changed determination.

1.2 The Policy does not define the terms on which compliance depends.

The Policy is titled for research involving biohazards and does not define "biohazard." It also uses, without definition: organism, transgenic, vector, GDMO, gene drive modified biological agent, adventitious agent, incident, release, shedding, peptide, and potential risk to human health. Several were also undefined in the NIH Guidelines, which makes this the right occasion to correct the problem rather than carry it forward.

"Organism" is the most consequential. It is used inconsistently and is not readily definable, and as written it leaves the relationship between Section IV-2 (genetically modified organisms) and Section IV-3 (transgenic organisms at BSL-1/ABSL-1) unresolvable, because the Policy never says how the two differ. I recommend replacing it throughout with the specific categories intended — bacteria, fungi, archaea, protists, viruses, animals — and stating expressly if there is a further category of concern, such as a biological agent produced through synthetic biology that does not fall within conventional taxonomy.

"Potential risk to human health" carries the entire scope boundary and is undefined. As written it could reach chemical, radiological or physical hazards already regulated by other federal agencies, which I do not believe NIH intends. NIH should define it as the potential to cause human disease or adverse health effects arising from the biological materials within the Policy's scope, state expressly that the Policy does not address non-biological hazards, and identify who applies the threshold and against what standard.

"Toxin" should be limited to substances of living biological origin and should exclude proteins and peptides whose primary adverse effect is an allergic or hypersensitivity response. As drafted, read together with Section IV-3's category for non-Select-Agent biological toxin proteins, the Policy reaches common laboratory reagents of biological origin.

1.3 The definition of genetic modification captures unintentional change and routine virology.

The definition includes stable alterations introduced by passaging, reassortment, or chemical or radiological means, and does not distinguish deliberate engineering from change that occurs incidentally. Serial passage of any virus in cell culture produces unintended genomic alterations; so do chemical mutagenesis, irradiation, and selection under drug pressure. Investigators performing entirely conventional work would be out of compliance immediately and without knowing it.

The definition also reaches nucleic acid molecules that "can be transcribed or translated," which includes transfection of a synthetic mRNA into a cell line. This produces an unexplained inversion: the draft removes deliberate administration of recombinant nucleic acids to human participants from the scope that Section III-C-1 of the Guidelines currently covers, while bringing transfection of the same material into cultured cells within scope. NIH should state the risk assessment supporting the conclusion that the in vitro use warrants review and the in vivo use does not.

I recommend the definition be rewritten to cover intentional, stable modification of the genome, with oversight keyed to the resulting phenotype, and that NIH address expressly how it applies to reverse genetics and viral rescue systems, including recovery of wild-type virus from cloned cDNA.

1.4 There is no review pathway for agents that lack a BMBL entry but are not emerging, novel or zoonotic.

Section IV-1 provides federal review for emerging, novel or zoonotic agents lacking an RG classification or minimum containment recommendation in the BMBL. The Policy provides nothing for the much larger set of agents that are none of those things and still have no entry. Human metapneumovirus, non-polio enteroviruses, human parainfluenza virus 5 and Sendai virus are long-established laboratory agents handled routinely at BSL-2, with no risk group in the NIH Guidelines and no BMBL agent summary statement.

Read literally, they fall into Section IV-1 and require NIH approval — an outcome that cannot be intended, given that wild-type RG3 and RG4 agents require only IBC review under Section IV-2. The same problem applies to human and animal microbiota: if research with common commensal genera requires federal review, it is not clear that an investigator can collect a human or animal specimen without entering noncompliance.

NIH should state expressly that local IBCs may perform the risk assessment and assign containment for agents in this category, reserving federal review for circumstances involving substantial uncertainty or potentially significant public or environmental consequence.

1.5 The Policy does not say who assigns risk groups.

Risk group assignment determines both the review tier and, for RG1, whether research is within scope at all — the Policy places wild-type RG1 agents outside its scope while also stating that absence from the RG2–RG4 listing does not imply classification as RG1. With Appendix B of the Guidelines retired, there is

no authoritative source for these assignments and no stated authority to make them.

NIH should either publish and maintain a version-controlled list of RG1 through RG4 agents supplementing the BMBL, using Appendix B as its backbone and including RG1 agents expressly, or state in the Policy that the local IBC holds that authority. Participation by USDA, CDC and other agencies in a single list, including plant and agricultural considerations, would be valuable.

1.6 Section IV-2 operates as a catch-all with no stated boundary.

Section IV-2 requires IBC approval for initial submissions "not otherwise specified in other sections." A catch-all of that kind requires a corresponding section stating what falls outside the Policy. Institutions cannot operate from isolated bracketed notes, such as the one indicating that experiments with RG1 wild-type biological agents are not subject to the Policy. Without an express out-of-scope section, practice will vary widely between unintentional noncompliance and defensive over-review of work the Policy never meant to reach.

1.7 The relationship to other federal oversight must be stated precisely.

Section II provides that research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained." Section I-A-1 of the current Guidelines is narrower and clearer: another agency's approval may substitute for NIH review or approval. It does not displace institutional IBC oversight. The draft's broader language can be read to eliminate both, and it conflicts with the Policy's own clinical provisions, which require IBC approval in addition to all other regulatory approvals.

Concretely: an investigator registered with the Federal Select Agent Program to work with a wild-type RG4 agent needs to know whether IBC approval under Section IV-2 is still required. An investigator registered with FSAP to construct recombinant viruses in that backbone needs to know whether NIH and IBC approval are required in addition. And an institution needs to know whether an incident in high containment involving a registered Select Agent is reported to NIH and posted publicly, notwithstanding FSAP's own restrictions on security-sensitive information. NIH should state which Policy requirements survive another agency's jurisdiction, and whether approvals are sequential or concurrent.

(Implementation timing is addressed under Question 6.)

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 2.1 The tiered structure is the right approach, and delegated review should be made to work as intended.

The three-tier structure is a genuine improvement over the current framework, and the provision permitting delegated approval of lower-risk research — comparable to the designated member review long used by IACUCs — should meaningfully reduce the time the full committee spends on work that does not require its collective judgment. I also have no objection to bringing wild-type RG2, RG3 and RG4 biological agents within the Policy's scope. Institutions conducting that work already require IBC approval for it, and stating the requirement federally creates no new burden.

Two features of the delegated pathway undercut its purpose. First, requiring every delegated approval to be reported in full at the next convened meeting and included in publicly posted minutes recreates much of the workload the pathway exists to avoid. Institutions should be permitted to provide the committee with a concise approval log or aggregate report, with complete records retained and available for audit, and the Policy should define what role the full committee retains after a delegated approval has been granted.

Second, the Policy should make delegation under Section IV-3 optional rather than mandatory. Institutions differ in committee structure, meeting frequency and administrative capacity, and some will find full-committee review of a given category simpler than administering a delegated process for it. The Policy should also state expressly that delegated review is available for minor amendments — including amendments to research originally reviewed under Section IV-2 — and should distinguish administrative changes from changes requiring reassessment of risk.

Where delegated review is used, the Policy should specify a procedure: notice to all members of a pending review with access to the submission materials; a reasonable period, defined in written institutional procedures, within which any member may request full committee review; assignment of qualified, unconflicted member reviewers; agreement among multiple reviewers, with unresolved differences referred to the full committee; and communication of the approval to the committee for inclusion in its records.

2.2 The Policy provides no rule for resolving overlapping categories.

Sections IV-2 and IV-3 overlap substantially. Genetically modified cells, viruses and organisms appear in Section IV-2 as full-committee work, while several subsets of the same research — well-characterized cell lines, genetically modified RG1 agents, plasmids and non-integrating vectors expressing low-risk transgenes — appear in Section IV-3 as delegable. Nothing in the Policy states which controls. The same construct transfected into the same cell line can be classified in either tier depending on which sentence the reviewer reads first.

The final Policy should state expressly that the most specific applicable category controls, and should include a review-pathway decision table with worked examples spanning full committee review, delegated review, registration, exemption and NIH review. The table should resolve routine cases that will otherwise be decided inconsistently across institutions: transfection of an established cell line, use of a previously edited cell line, a change in personnel, and a change in laboratory room. A room change should not be treated as administrative without first assessing its containment implications. The Policy should also state how de novo renewals are categorized.

2.3 Several categories are placed in tiers disproportionate to their risk.

The categories identified in Section 1.1 above are not merely formerly exempt; they are placed at review levels that do not correspond to any articulated biosafety concern. The Policy does not describe how oversight of this research increases biosafety or biosecurity, and in several cases the administrative burden is substantial while the risk is negligible.

Genetically modified cells, viruses and organisms (Section IV-2). This category is misplaced and internally inconsistent. Genetic modification of cells presents very low biosafety risk absent introduction of nucleic acids from RG3 or RG4 agents or sequences encoding toxins, and such work should be at most within Section IV-3, if not exempt. The category also contains terms that are undefined or poorly defined and that conflict with other categories: as written "organism" appears to include animals notwithstanding the separate transgenic category in Section IV-3; "vector" does not distinguish viral vectors from arthropod disease vectors; and "gene drive modified biological agent" cannot be reconciled with the Policy's own definition of biological agent, while its relationship to the undefined acronym GDMO is unstated.

I recommend this category be removed or extensively rewritten as follows:

- The definition of genetic modification should be limited to intentional stable alterations of the genome, as described in Section 1.3 above. Definitions for organism, vector, GDMO and gene drive modified biological agent must be added to the Policy or the terms removed.
- Research with genetically modified RG3 and RG4 biological agents should require IBC approval.
- Research with genetically modified RG2 biological agents should be eligible for delegated approval.
- Research with gene drive modified organisms should require IBC approval.
- Review of research with genetically modified cells should depend on the modification, with pathways ranging from IBC approval through delegated approval to complete exemption from the Policy.

Research with genetically modified RG1 biological agents (Section IV-3). Certain research with RG1 agents not involving DNA from RG3, RG4 or restricted organisms is exempt under Appendices C-II through C-V, having been determined by the NIH Director not to present a significant risk to health or the environment. This category contradicts that determination without explanation. I recommend it be removed.

Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes (Section IV-3). This research is of low biosafety and biosecurity risk and the Policy does not describe how regulating it advances either. Investigators generate plasmids continuously, and requiring prior approval for them will produce a severe bottleneck and extensive unintentional noncompliance. The Policy also fails to state the extent of what must be registered — the backbone alone, the backbone with each gene to be inserted, or each gene with each mutation of that gene. I recommend this category be removed.

Research with well-characterized cell lines (Section IV-3). The Policy does not identify the biosafety concern this category addresses, nor what must be registered: that an investigator works with cell lines at all, each individual line, or whether an entire catalog may be approved at once. Registration of this work will produce extensive unintentional noncompliance and crippling administrative burden for investigators and committees alike, with no corresponding benefit. I recommend this category be removed.

Research conducted with transgenic organisms at BSL-1/ABSL-1 (Section IV-3). For the reasons given in

Section 1.1, work with transgenic rodents that may be housed at ABSL-1 should not require IBC approval. I recognize that research with some transgenic animals may not yet have accumulated a comparable safety record and should continue to require approval before initiation. NIH should also consider whether transgenic fruit flies and zebrafish warrant exemption on the strength of their own track record. I recommend this category be rewritten as: Research conducted with transgenic animals, other than transgenic rodents, fruit flies and zebrafish, that may be housed at minimum BSL-1/ABSL-1/ACL-1. Consistent with Section 1.2, "organism" should be replaced with "animal" in this category.

Research with biological toxin proteins not on the Select Agent list (Section IV-3). Under the Policy's definition of toxin, this category reaches food and animal allergens and other common reagents of biological origin, which cannot be the intent. There is also a conflict between the category's wording and the definition itself that makes the scope difficult to determine. Work with toxins is in many institutions already overseen by a chemical safety committee, and additional committee review will not increase safety. I recommend this category be removed. If it is retained, it should be rewritten as: Research with biological toxin proteins with an LD_{50} in vertebrates of less than 100 micrograms per kilogram of body weight — and the Policy should include a list of toxins classified under it, using the LD_{50} classification currently available from NIH OSP under Appendix F-1 of the Guidelines as its backbone.

Institutions should additionally be permitted to clear work in any of these categories through a documented internal screening process where that process determines the work presents minimal biosafety risk, and should retain authority to elevate work to a higher tier when local circumstances warrant.

2.4 Primary cells "that may be contaminated by adventitious agents" sits at the wrong tier and rests on an undefined term.

Section IV-2 requires full IBC approval for research with primary cells that may be contaminated by adventitious agents. The Policy does not define "adventitious agent," so institutions cannot determine what is covered. Read literally, "may be contaminated" reaches nearly all primary cell work, including cells from low-risk sources, which conflicts directly with Section IV-3's treatment of well-characterized cell lines as delegable.

The tier assignment is also inverted. Research with material that may contain a contaminant requires full committee review, while research with a known RG2 agent requires only delegated review. For clinical specimens suspected to contain higher-consequence pathogens, the BMBL recommends BSL-2 practices, containment equipment and facilities for routine handling of specimens of human or animal origin. The Policy should harmonize the level of review accordingly.

I recommend this category be removed. If it is retained: "adventitious agent" must be defined — for example, as an unintended biological agent present in cells, tissues, animals or reagents that was not deliberately introduced and is not part of the planned research; "may be contaminated" should be replaced with risk-based criteria tied to the source and screening status of the material, such as unscreened primary human or non-human primate cells; the work should not require approval where the institution complies with the OSHA Bloodborne Pathogens Standard or its equivalent; and in no case

should it require more than delegated review under Section IV-3. If the intent is instead to reach primary cells potentially contaminated by any unknown biohazard, such as field samples, that should be stated and defined.

2.5 Federal review as drafted leaves no path to study a newly identified agent.

Section IV-1 requires NIH and IBC approval for research involving emerging, novel or zoonotic agents for which an RG classification or minimum containment recommendation is not available in the BMBL. For investigators whose research involves identifying previously unrecognized agents, this creates a closed loop. Once an agent is identified and found to have no assigned risk group and no BMBL recommendation, the research requires NIH approval — but without the ability to work with the agent, the investigator cannot generate the data on which NIH would base its risk assessment. The Policy offers no route out of this.

The practical consequence is that this work will not be done in the United States. Investigators will not undertake projects that cannot be initiated, and agent discovery and characterization will shift to institutions in other countries, leaving US researchers dependent on others for the foundational characterization of agents that may later matter a great deal.

The trigger is also drawn far more broadly than the category of genuinely high-consequence uncertainty it appears aimed at. As written it captures many uncommon agents currently handled routinely at BSL-1 and BSL-2, including organisms recovered during environmental screens, and — as described in Section 1.4 — well-established agents that are simply absent from the BMBL.

I recommend the Policy describe a clear approval pathway permitting investigators to generate the data required for a risk assessment, with that review performed by the local IBC. More generally, NIH should consolidate the overlapping petition provisions, define narrowly when an emerging, novel, zoonotic or unlisted agent requires federal review, include an explicit decision rule for the case where reference information is absent, permit qualified IBCs to make interim or final containment determinations for well-characterized agents, and reserve federal preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequence.

2.6 "Emerging agent" is not a stable category and the Policy does not say who applies it.

The Policy does not state who determines that an agent is emerging. If that determination rests with the local IBC, the Policy should say so. If it does not, NIH should issue rapid dissemination notices identifying emerging agents so that institutions can avoid noncompliance with a classification they had no way to anticipate.

The Policy also does not describe how an agent ceases to be emerging. Does the designation persist until NIH first reviews the agent under Section IV-1, until a risk group is assigned, or until the agent appears in the next edition of the BMBL? Nor is it clear whether the definition reaches a well-characterized agent that exhibits a change in pathogenicity or transmission: had this Policy been in effect, it is not evident whether the recent outbreaks of Zika virus, mpox virus or Andes virus would have qualified, or whether

the designation would attach to the agent or only to the specific strain. Applied today, it is not clear which agents would qualify — highly pathogenic avian influenza H5N1, or SARS-CoV-2.

These are not hypothetical distinctions. They determine whether an institution must obtain federal approval before beginning work, and an institution that guesses wrong is noncompliant.

2.7 Recombinant agents constructed within a family should be reviewable by the IBC.

The Policy's definition of novel agent captures recombinant constructs assembled from parental agents that already have assigned risk groups or recommended biosafety levels. Investigators generate such constructs routinely to study the basic biology of these agents — exchanging a gene between two members of the same viral family, for instance, where both parents are well characterized and the containment appropriate to each is already established.

Research of this kind does not fit the Policy's own conception of higher-risk work requiring federal review. These experiments currently fall within Section III-D of the NIH Guidelines, which demonstrates that for decades NIH has determined they can be reviewed by the local IBC. It would also be inconsistent to require federal approval here while Section IV-2 assigns research with wild-type RG3 and RG4 agents to local review.

I recommend that the Policy permit IBC review of research involving recombinant agents generated within the same family for viruses, or the same genus for bacteria and fungi, and of research involving recombinant agents where the natural source agents have assigned risk groups or recommended biosafety levels.

2.8 Federal review requires a stated reviewer, published determinations and a response timeline.

Who reviews. The Policy replaces two former categories — research requiring NIH Director approval under Section III-A of the Guidelines and research requiring NIH OSP approval under Section III-B — with a single category requiring "NIH approval," without stating which office or person performs it. Institutions can reasonably expect materially different response times from the Director and from OSP, and OSP is staffed with subject matter experts across the range of biomedical science in a way no single official can be. The Policy should state, within the responsibilities of NIH in Section III-D, who is responsible for each duty assigned to NIH, and should publish submission checklists, completeness criteria, response targets and escalation routes.

Determinations must be reusable. The Policy implies a workflow for lowering containment — an institution submits an initial request for wild-type or genetically modified RG3 or RG4 agents; NIH determines whether lower containment is appropriate; NIH publishes approved determinations; subsequent research with those agents may thereafter be approved by the IBC alone. That workflow should be stated expressly, including an unambiguous statement that once NIH has published a determination, other institutions need not obtain their own approval. This would correct a significant limitation of the current system, under which approvals extend only to a single investigator at a single institution, requiring other investigators at the same institution to seek the same determination again.

NIH should publish all containment determinations — agent, modification, approved containment and rationale — in a searchable public resource that other institutions may rely upon, not only the RG3 and RG4 lower-containment determinations Section III-D currently commits to publishing. Section III-D makes no equivalent commitment for emerging or novel agents, and it should. The Policy should state the method and minimum frequency of publication, define what constitutes substantial equivalence and which deviations are permissible, identify who determines whether a prior determination applies, and state what documentation is expected. It should also set a target response timeline — 30 calendar days would be reasonable — rather than relying on the word "timely."

Finally, the Policy should state how much information accompanies a published determination, and specifically whether publication would include security-sensitive information or unpublished data.

Risk group and containment determinations should apply broadly. Determinations of risk group and recommended biosafety level should apply to all investigators and all institutions subject to the Policy, not to the requesting investigator alone. Differences in recommended containment arising from geography, climate or research conducted outside the United States should be accounted for in implementing this change.

2.9 The three-year approval ceiling imposes burden without a stated safety benefit.

The Policy provides that approval "should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required." It does not describe how biosafety or biosecurity is improved by this limit. Research projects continue over years and decades, and they rarely incorporate changes that significantly alter the original risk assessment; those that do are already captured by the requirement to obtain approval for significant changes before implementation.

Requiring de novo submission on a fixed three-year cycle will substantially increase administrative burden for both investigators and committees for little or no gain in safety. I recommend the requirement be removed, and that the Policy instead provide for risk-based continuing review between renewals. If the requirement is retained, the Policy should expressly permit grandfathering of previously approved registrations carrying approval periods longer than three years.

3. Continued utility of Risk Groups: 3.1 Risk Groups retain utility as hazard descriptors, but should not independently determine containment or review level.

Risk Groups remain valuable tools for initial hazard communication and agent characterization, and I do not recommend that NIH abandon them. They should not, however, independently dictate either the containment level at which research is conducted or the tier at which it is reviewed. The final Policy must preserve site-specific and experiment-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities and available mitigations.

This is consistent with the draft's own Section V-E, which acknowledges that Risk Groups and Biosafety Levels are related but non-equivalent concepts. A Risk Group describes the characteristics of an agent; a Biosafety Level describes a set of containment practices, equipment and facilities. The problem is that

other provisions of the Policy do not follow Section V-E's lead, and several of them treat the two as interchangeable.

3.2 Risk Groups cannot bear the structural weight the Policy places on them.

Section IV keys multiple oversight categories directly to Risk Group — research with RG3 or RG4 wild-type agents to Section IV-2, RG2 wild-type agents and genetically modified RG1 agents to Section IV-3, and lower-containment requests to Section IV-1 depending on the agent's Risk Group. A classification system used this way must be precise, authoritative and well matched to the decision it is being asked to drive. Risk Groups are not, for several reasons:

- They describe risk to a healthy adult in the community. Section V-A states that Risk Groups reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some personnel are more susceptible because of medications, immune status or pregnancy.
- They reflect community exposure, not laboratory conditions. The concentrations, volumes and manipulations used in a laboratory differ greatly from any exposure occurring in the community or the environment.
- They provide no baseline for novel constructs. Recombinant and synthetic nucleic acid constructs do not exist in the community until they have been made and studied in a laboratory, which is the purpose of the laboratory. There is nothing for a community-based classification to describe.
- They cover only human etiologic agents. The Policy's conception of biohazards is broader than agents that cause human disease, so Risk Group cannot serve as the general basis for classifying biohazardous material.
- They are routinely misinterpreted. Investigators and federal agencies alike treat the Risk Group number as a containment requirement. This is a safety problem in both directions: it invites containment decisions that are not grounded in the actual experiment, and it substitutes a label for the assessment that should be performed.

Retained as one input to the first step of a risk assessment — characterizing the hazard — Risk Groups are useful. Used as the trigger for an oversight tier, they import all of the limitations above into a compliance determination.

3.3 The petition provision contains a condition that cannot be satisfied.

The IBC Functions provision directs the committee to petition NIH to determine the minimum biocontainment level for emerging, novel or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and prohibits IBC approval of such research until authorized by NIH and other applicable entities. This provision has two defects.

First, it treats "RG classification" and "containment level" as alternative items that might be found in the BMBL, which contradicts Section V-E's own statement that the two are non-equivalent. NIH should use these terms consistently throughout the Policy.

Second, and more consequentially: the BMBL does not assign Risk Groups. It provides agent summary

statements with recommended Biosafety Levels. A condition framed as the absence of an RG classification "in the BMBL" can never be met, because no RG classification is available there for any agent. As drafted, the provision either applies to every agent or to none, depending on how a reader resolves an error in its premise. This language requires correction.

3.4 The petition requirement is undefined as to who else must approve, and overbroad as to what it reaches.

The provision conditions IBC approval on authorization by NIH "and any other applicable Federal, State, or local entities." That phrase introduces substantial ambiguity. NIH should identify which entities are contemplated, specify whether their approvals are sequential or concurrent, state how coordination is to occur, and establish a resolution pathway for the case where determinations conflict. An institution cannot comply with a requirement to obtain approvals from an unspecified set of authorities.

The requirement is also broader than its apparent purpose. As written it can be read to apply to non-pathogenic genetically modified constructs and to benign RG1 organisms that are not specifically named in the BMBL — which is to say, most of them. NIH should state expressly that unlisted, non-pathogenic RG1 agents do not require federal petitioning. Without that clarification, the petition pathway will accumulate a backlog of submissions concerning agents that present no meaningful hazard, at the expense of the submissions that warrant federal attention.

3.5 Because Section IV depends on Risk Group assignments, the absence of an authoritative source is a structural problem.

As described in Section 1.5, Risk Group assignments have been removed from the former Appendix B of the Guidelines and do not appear in the BMBL, while the Policy continues to assign oversight tiers by Risk Group and places wild-type RG1 agents outside its scope entirely. There is presently no authoritative source for the classification on which the entire Section IV structure depends.

NIH should provide an authoritative, version-controlled federal repository of Risk Group assignments, or publish clear objective criteria by which institutions are to assign Risk Groups to non-recombinant agents, or state expressly that the local IBC holds that authority. Absent one of these, institutions will reach conflicting conclusions about the same agent, and the national consistency the Policy is intended to produce will not be achieved. Where NIH or an IBC makes a containment determination, it should apply to all investigators and institutions subject to the Policy rather than to the requesting investigator alone; Section 2.8 above addresses publication and reuse of those determinations.

The Policy should also provide a transition rule for research already under IBC approval. Many institutions have agents in active use that have no Risk Group assignment and no BMBL agent summary statement, for which the local committee has assigned a containment level based on a documented risk assessment and the published literature. NIH should state whether those determinations remain valid, whether they must be submitted for federal confirmation, and on what schedule — and it should not require that ongoing work stop pending that process.

3.6 Rigid containment minima conflict with the performance-based risk assessment the Policy otherwise requires.

The Policy requires experiment-specific risk assessment in Sections V-A through V-E, then imposes fixed containment prescriptions that override it in particular cases. Two examples warrant revision.

A universal minimum of BSL-2 for gene drive modified organisms does not map onto the specialized containment systems in which much of this work is appropriately performed — arthropod containment levels, greenhouse standards, and aquatic facilities each describe containment in terms that do not correspond to laboratory biosafety levels. NIH should permit equivalent risk-based containment modalities and issue specialized guidance for these systems rather than requiring institutions to translate an ill-fitting minimum.

Containment requirements for influenza constructs should specify the phenotypic traits, host range and pathogenicity markers that warrant enhanced containment, rather than sweeping in constructs on the basis of raw genomic segment proportions. A requirement keyed to the proportion of a genome drawn from a particular source captures constructs whose phenotype does not warrant the containment imposed, and may fail to capture constructs whose phenotype does.

3.7 Risk assessment guidance would do more to improve consistency than classification would.

If Risk Groups are to serve as one input to risk assessment rather than as a determinant of oversight, the Policy and its implementation materials should give institutions a usable method. I recommend NIH:

- State plainly how the Policy's controlling requirements and its reference guidance interact, and how differences between them are resolved.
- Permit qualified staff to support risk assessments while investigators retain their own responsibilities and the IBC independently evaluates the conclusions reached.
- Provide a concise documentation format covering likelihood, severity, exposure pathways, uncertainty, controls, residual risk and decision authority — so that an assessment can be reviewed, compared and audited.
- Publish worked examples for the categories institutions find hardest: attenuated and opportunistic agents; toxin potency, dose and form; prions and self-aggregating proteins; and validated inactivation.
- Address how short, unknown, proprietary and computationally designed sequences are to be assessed, including how encoded function, expected phenotype and residual uncertainty bear on the containment decision.
- Distinguish functional gene drives from components, split systems and intermediates, which present materially different risks and should not be treated identically.
- Clarify how influenza strain, segment and pseudotype combinations are assessed, and when a previous containment determination remains applicable to a related construct.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comments at this time.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 5.1 The effort to establish clearer federal thresholds is welcome and should be carried further.

I support the draft's effort to identify specific categories of events warranting immediate notification and follow-up reporting. Clear thresholds improve consistency across institutions and allow NIH to focus its attention on events with genuine potential public health or community significance.

The definition of a reportable incident should be refined, and the thresholds stated more precisely, so that a risk-based approach is applied consistently rather than interpreted institution by institution. The sections below identify where the current language does not yet permit that.

5.2 The Policy must define the terms on which reporting obligations depend.

The reporting provisions turn on terms the Policy does not define: incident, release, potential exposure, minor spill, improper disposition, and the distinction between basic first aid and agent-specific medical treatment. An institution cannot build a compliant reporting workflow around undefined triggers, and the result will be inconsistent practice and unintentional noncompliance rather than better information reaching NIH.

I recommend NIH adopt the following definitions in Section II:

- Incident: A confirmed theft, loss, or release — such as an occupational exposure or a release outside the defined biocontainment barriers — of biological material under the scope of the Policy.
- Release (loss of containment or occupational exposure): A failure in biosafety practice and/or equipment such that there is occupational exposure of the person or persons working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
- Potential exposure: An event occurring in the active presence of a biohazard where primary barriers or personal protective equipment were breached, creating a credible exposure pathway. Equipment or PPE failures occurring in the absence of active biohazardous agents are not potential exposures.
- Minor spill: A defined term, replacing the current formulation that minor spills "generally do not need to be reported." Subjective qualifiers such as "generally" should be removed throughout.

NIH should also align "medical treatment" explicitly with the OSHA standard — care beyond basic first aid — and state that precautionary, non-specific post-exposure prophylaxis and routine medical consultation do not constitute agent-specific treatment triggering 24-hour federal reporting. The Policy should additionally clarify how precautionary medical evaluation, prophylaxis, potential adventitious agents, and mixed or uncertain exposures bear on reportability.

5.3 The Policy should not treat maintained containment as a potential release.

The draft requires reporting of "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly." This requirement is internally contradictory. Containment at higher biosafety levels is built on layered engineering barriers precisely so that the failure of one component does not result in the escape of biological material. When redundant systems function

properly and containment is maintained, no release has occurred and none was imminent; characterizing the event as a potential release describes the system working as designed as though it had failed.

Read literally, the provision makes a spill fully contained within a biosafety cabinet a reportable event. At BSL-3, a spill outside primary containment is a breach requiring room evacuation and air clearance, and directional airflow and exhaust filtration are what prevent escape from the room — these are meaningful distinctions that the current language collapses.

I recommend NIH remove this phrasing and instead:

- Anchor "release" to containment boundaries, as defined in Section 5.2 above.
- Calibrate reporting expectations to the containment level, recognizing that higher containment incorporates redundant secondary barriers that prevent environmental dissemination even during procedural disruption.
- State that PPE or equipment failures occurring without exposure to an active agent are not reportable incidents.
- Clarify whether any event occurring at BSL-3 or BSL-4 is reportable regardless of whether it bears on biohazard containment, and distinguish equipment malfunctions where backup containment was maintained from events where containment was actually compromised.

5.4 Administrative noncompliance should be distinguished from substantive noncompliance.

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories, with no distinction drawn between kinds of noncompliance. Late paperwork, a minor recordkeeping error or a missed administrative deadline are not the same as initiating research without approval or lowering containment without authorization, and they should not be reported on the same timeline.

I recommend the Policy distinguish administrative noncompliance from substantive biosafety noncompliance, identify which violations are reportable regardless of risk and which are eligible for internal correction, and state plainly that administrative noncompliance and low-risk items never require 24-hour reporting. "Significant violations" should be defined as noncompliance that directly compromises containment or involves initiation of unapproved high-consequence research.

5.5 The reporting workflow needs mechanics institutions can actually implement.

The Policy establishes a 24-hour notification and a 30-day report without specifying how either is operated. I recommend NIH address the following, ideally in the form of a reporting decision table accompanying the template:

- Who receives the initial report, and — critically — whose awareness starts the 24-hour clock. An institution cannot demonstrate timely notification without knowing when the clock began.
- The minimum information an initial notification must contain, and how uncertainty is to be handled

when the facts are not yet established.
- When the 30-day period begins, and whether an interim report is permitted where the investigation remains incomplete at that point.
- That investigations may be conducted jointly by qualified biosafety, occupational health, clinical and veterinary personnel, with escalation to the IBC based on risk, recurrence or unresolved concerns, while preserving each body's own reporting duties. Qualified response personnel should be able to investigate and take immediate protective action without waiting for a convened meeting.

Paired worked examples would resolve most of the ambiguity at once: a contained and disinfected spill with no exposure against an event creating a credible exposure or release; an equipment malfunction with backup containment maintained against an actual containment failure; and an administrative lapse against unauthorized initiation of work. In each pairing, NIH should identify the specific facts that change the reporting pathway.

5.6 Regulatory reporting should be decoupled from public website posting.

Section III-B requires institutions to post all incident reports on a public-facing website, including reports of lower-risk incidents that are managed institutionally and are never reported to NIH. The Draft Incident Reporting Template requires identification of the Principal Investigator and does not permit redaction of the PI's name, expressly excluding the PI from the exemption that allows other involved individuals to remain unidentified, on the rationale that information available from public sources may not be redacted. I support appropriate transparency about significant biosafety incidents and institutional responses, but the disclosure requirements as drafted produce four consequences that work against the Policy's own objectives.

Personnel can be identified from posted reports. Reports containing the PI's name, the agent, the grant number and the facility location frequently provide enough detail to identify the individuals involved in an incident, even where those individuals are nominally unidentified. The information required for public posting may therefore disclose what amounts to individual medical information, with attendant legal exposure for the institution.

Identification creates personal safety risk. Linking named investigators to specific agents, funding and facility locations exposes researchers and animal care personnel to harassment, threats and targeted cyber-attacks. This concern is most acute in animal research and in other areas that have historically attracted targeting, and it applies equally to the continuously updated IBC rosters and the contact information for IBC chairs, Biological Safety Officers and committee contacts contemplated by the Biosafety Assurance.

Aggregated postings constitute a research security exposure. Publicly posted incident reports and committee minutes accumulate over time and across institutions. Taken together they would reveal which agents institutions work with, the direction of unpublished work in individual laboratories, the locations of high-containment research, and which facilities have experienced failures of equipment, training or procedure. Automated collection tools can assemble these records into a map of national high-consequence research capability. That outcome is difficult to reconcile with federal research

security policy and with the Federal Select Agent Program's own restrictions on security-sensitive information. NIH should coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, before establishing public disclosure requirements.

Posting suppresses the reporting the Policy wants to encourage. Requiring minor, fully mitigated events to appear in public view discourages internal reporting of near-misses and borderline events, out of concern for public reaction and institutional reputation. The Policy elsewhere seeks to build a safety-learning system; this provision works directly against it.

NIH should calibrate disclosure to the significance and potential public health consequence of the incident. For lower-risk incidents that do not meet federal reporting thresholds, de-identified reports, standardized summaries or aggregated reporting would provide meaningful transparency and genuine opportunity for shared learning. NIH should also state the public interest or biosafety rationale for requiring PI identification in individual reports, and consider whether that identification contributes anything to understanding or preventing incidents. As a general matter, routine public disclosure should not extend to investigator names, grant or internal project numbers, sensitive animal research information, select agent and toxin information, proprietary materials and research outcomes, identifying facility information, or other details that could compromise safety, security or personnel protection.

The better route to transparency is aggregate reporting. NIH can meet its transparency objectives by publishing aggregated, de-identified incident data — an annual incident summary with trends, contributing factors and lessons learned — and through the National Biosafety Data and Safety Analysis Center, while full records remain available to NIH and other authorized reviewers to support investigation of laboratory-acquired infections and other public health needs. A confidential national reporting system of this kind is only useful if its boundaries are clearly drawn and if institutions and investigators trust that voluntary submissions will not be used for enforcement. NIH should state expressly how confidential voluntary reporting to the NBDSAC interacts with mandatory reporting and public posting, and identify the limits of that confidentiality, so institutions can participate without uncertainty about their disclosure obligations.

5.7 If public posting is retained, redaction standards and deadlines must be specified.

Should NIH retain a public posting requirement, two elements are presently missing.

First, redaction. The Policy should permit redaction of PI names, grant identifiers, and information necessary to protect proprietary and security-sensitive material. The current formulation of "appropriate and allowable" redactions should be replaced with "specific and allowed" redactions, accompanied by standardized examples that identify what institutions may withhold on safety or security grounds. Because state public-records laws vary and may constrain what an institution is permitted to withhold, NIH guidance should distinguish the federal posting and redaction standard from any additional disclosure obligations imposed by state law.

Second, timing. The Policy ties posting to NIH's final response without defining when that response

occurs. An institution cannot be held to a posting deadline that depends on an open-ended federal review. NIH should establish a defined endpoint for its final response, and state what an institution is to do if that endpoint passes without one.

5.8 The minutes template should specify content elements rather than a format.

Institutions differ in meeting structure, recordkeeping practice, information systems, and use of software platforms that may generate meeting records or summaries automatically. A mandated template will require many institutions to maintain parallel records — one set for operations and one for compliance — without improving the information NIH or the public receives.

NIH should instead require the specific content elements needed to support transparency and accountability: review category, approval decision, containment level, and any required conditions of approval. A content-based requirement allows institutions to use their existing processes and systems while ensuring the required information is consistently documented and made available, subject to appropriate protection of sensitive information. The same flexibility should apply to the documentation format of both public meeting minutes and incident reports.

6. Other feedback relevant to this resource: 6.1 A six-month effective date is not implementable; the Policy needs at least 24 months and a phased transition.

The proposed six-month effective date is not realistic given the scope of what institutions must accomplish before covered research may continue. Within that window an institution would need to inventory all newly covered research, obtain an approved Biosafety Assurance, revise institutional policies, redesign electronic submission and records systems, build public-facing posting processes, establish redaction standards, revise incident response and reporting workflows, train investigators and committee members on requirements that do not yet exist in final form, secure institutional approvals and funding for all of it, and in some cases establish an entirely new committee.

The Assurance requirement compounds the problem. No covered research may proceed after the effective date without a written Biosafety Assurance approved by NIH. That places every institution's entire covered portfolio behind a single federal approval, submitted on roughly the same schedule as every other institution's. It is not evident that NIH will have the staff to review and approve several hundred Assurances within six months of publication, and the consequence of a backlog falls on research that is already underway and already approved locally.

I recommend NIH provide at least 24 months after publication of both the final Policy and the complete implementation materials, structured as follows:

- Phased milestones for inventory of covered research, staffing, training, systems changes, Assurance approval, and conversion of existing registrations — so that institutions can sequence the work rather than attempt all of it simultaneously.
- Provisional or deemed assurance mechanisms that prevent interruption of ongoing research where federal review is incomplete through no fault of the institution.
- Staged conversion of existing approvals. Registrations approved under the NIH Guidelines should be

permitted to convert at their next significant amendment or scheduled renewal rather than all at once, with appropriate safeguards and with priority given to higher-risk work.
- Preservation of staggered renewal cycles. Institutions have deliberately distributed renewal dates across the year. A conversion process that collapses them into a single cohort would create a backlog that persists for years and would degrade review quality for the work that most needs attention.

6.2 The templates and tools should be piloted before they become mandatory.

NIH should pilot the Biosafety Assurance, meeting minutes, incident reporting, risk assessment and delegated review tools with institutions representing a range of sizes, missions, research portfolios and program maturity. The findings should be published and used to refine the instruments for burden, clarity and usability before compliance with them is required.

This is worth the time it costs. Several of the drafting problems identified elsewhere in these comments — the reference to Risk Group classifications in the BMBL, the requirement to report failures where redundant systems maintained containment, the absence of a precedence rule between review tiers — are the kind of issue that surfaces immediately when a practitioner attempts to apply a document to a real submission, and that is difficult to see when reading it in the abstract.

6.3 The implementation resource set should be complete and available before the effective date.

The resources institutions will need include: a Biosafety Assurance template; model institutional policies; decision trees for determining review pathway and scope; risk assessment forms with worked examples; training material directed separately at committee members, biosafety staff, principal investigators and laboratory personnel; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database as described in Sections 1.5 and 2.8 above; and guidance addressing external, shared and consortium committee models.

There is also a transition-integrity question that the resource list should resolve. The NIH Guidelines carry substantial operative detail in their sections and appendices — containment specifications, laboratory practice requirements, training expectations, animal research provisions and occupational health requirements that are referenced by, but not reproduced in, the draft Policy. When the Guidelines are retired, those requirements need to land somewhere. NIH has indicated that implementation resources will draw on existing provisions, and I support preserving these risk-based protections. NIH should identify which of them remain mandatory, state whether any differ from the current Guidelines, name the authoritative document in which each will reside, and issue those materials concurrently with the final Policy and sufficiently in advance of the effective date for institutions to assess and demonstrate compliance.

6.4 NIH should publish a crosswalk between the final Policy and the requirements it replaces or overlaps.

Institutions have years of registrations, standard operating procedures, training materials and committee practice built on the section structure of the NIH Guidelines. Retiring that document without a mapping leaves every institution to independently determine which provision of the new Policy corresponds to

which provision of the old one — and they will reach different conclusions about the same question.

I recommend NIH publish a crosswalk between the final Policy, the NIH Guidelines it replaces, and other federal requirements governing research with biohazards, identifying for each area which framework governs, who owns the review, what information is shared between oversight bodies, and the applicable effective dates. This would reduce duplicative review and would give a concrete answer to the jurisdictional question raised in Section 1.7 above, rather than leaving it to be resolved institution by institution and case by case.

6.5 Two areas where additional guidance is specifically needed.

Prions and self-aggregating proteins. The Policy's definition limits this category to misfolded forms of proteins that self-propagate and cause neurodegenerative disease. That definition is reasonable, but applying it at the bench requires judgment the Policy does not support. NIH should provide practical examples and risk assessment guidance, including explicit direction on distinguishing in-scope materials from ordinary physiological protein aggregation. Without it, institutions will either over-report routine protein biochemistry or fail to identify work that genuinely falls within the category.

Computational and AI-assisted work. NIH should clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. This is a distinct question from the risk assessment of physical agents that were designed using computational or AI tools, and the two should be addressed separately. For the latter, NIH should provide practical guidance on evaluating the resulting biological hazards and on recognizing when a committee needs expertise it does not have.

6.6 The Policy should not operate as an unfunded mandate.

The draft substantially expands institutional obligations — scope of covered research, volume of review, documentation, public posting, assurance and reporting — without addressing how that work is to be resourced. Other federal regulatory agencies are required to assess the financial impact of policy changes before imposing them. In the absence of such an assessment here, NIH should address compliance cost directly.

I recommend NIH consider dedicated biosafety funding supplements; explicit statements of allowability for appropriate biosafety costs in direct or indirect cost structures; workforce development programs; shared training resources; and implementation support targeted to smaller and less-resourced institutions, for which the proportional burden of this Policy is greatest. Estimates of the additional effort NIH anticipates institutions will require would also allow institutional leadership to plan and budget rather than absorb the requirement unprepared.

6.7 The Policy should expressly permit flexible institutional arrangements.

The final Policy should state clearly that shared or consortium committees, external committee services and mutual-aid arrangements are permitted. Requirements for unaffiliated members and for specialized

expertise should be flexible enough to remain workable in small, rural or geographically isolated communities, and in communities dominated by a single institution where genuinely unaffiliated members are difficult to recruit — while still preserving meaningful independent input. Guidance addressing how these arrangements satisfy the Policy's requirements should be part of the implementation resource set.

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Request for Comment — NOT-OD-26-112 (August 19, 2026)

Introductory statement

RE: Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards (Request for Comment — NOT-OD-26-112, dated August 19, 2026)

To whom it may concern,

I am a principal investigator at a research-intensive academic medical center, directing a laboratory that conducts research with human respiratory viruses, including both wild-type agents and recombinant constructs, under BSL-2 and BSL-3 containment. My research is federally supported, and the work of my laboratory is reviewed and approved by my institution's Institutional Biosafety Committee under the current NIH Guidelines. I submit these comments in my individual capacity as an investigator subject to the proposed Policy. I have elected to comment anonymously, as the Notice permits.

I support the replacement of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules with risk-based biosafety oversight. The current framework is organized around a technology rather than around hazard, and after nearly fifty years it no longer maps cleanly onto how biomedical research is actually conducted. The objective NIH has set — oversight calibrated to risk, with federal attention reserved for the circumstances that warrant it and local judgment relied upon elsewhere — is the right one, and I offer these comments in support of it.

The draft Policy does not yet achieve that objective, and in its current form I do not believe it can be implemented as written. Its central difficulty is that it expands the volume of research requiring prior approval while leaving undefined many of the terms on which those approval obligations depend. The combination is what concerns me most: investigators and committees will be obligated to obtain approvals they cannot reliably identify, on a six-month timeline, with noncompliance as a term of federal funding. The predictable result is not improved biosafety but widespread unintentional noncompliance, substantial administrative effort directed at research that NIH has previously and expressly determined to be low risk, and less committee attention available for the work that genuinely warrants it.

These problems are correctable, and most of them are correctable through drafting rather than through any change in NIH's policy objectives. I respectfully request that NIH revise the Policy and publish a further draft for public comment before final issuance.

Priority recommendations

1. **Preserve the existing exemptions, or explain what changed.** The draft brings within its scope routine plasmid propagation in *E. coli* K-12, transfection of cultured cells, and BL1 transgenic rodent work — all of which the NIH Director has affirmatively determined do not present a significant risk to health or the environment. No revised risk assessment is offered. (Section 1.1, Section 2.3)
2. **Define the terms on which compliance depends.** *Biohazard*, *organism*, *vector*, *GDMO*, *adventitious agent*, *transgenic*, *incident*, *release*, *potential exposure* and *potential risk to human health* are each undefined and each load-bearing. (Sections 1.2, 5.2)
3. **Limit "genetic modification" to intentional, stable modification.** As drafted it captures serial passage, mutagenesis and selection, placing conventional virology in immediate noncompliance. (Section 1.3)
4. **Provide a review pathway for agents absent from the BMBL, and for newly identified agents.** The draft offers none for well-established agents that simply lack a BMBL entry, and for genuinely new agents it requires federal approval that depends on data the investigator cannot lawfully generate. (Sections 1.4, 2.5)
5. **Correct the petition provision in Section III-B.** It conditions IBC approval on the absence of a Risk Group classification in the BMBL. The BMBL does not assign Risk Groups, so the condition cannot be satisfied as written. (Section 3.3)
6. **Decouple incident reporting from public website posting.** Posting identifiable reports of minor, internally managed events creates personal safety and research security exposure while suppressing the near-miss reporting the Policy seeks to encourage. Aggregate, de-identified publication would serve transparency better. (Section 5.6)
7. **Allow at least 24 months, phased, and publish the implementation materials first.** Six months is not implementable, particularly given that no covered research may proceed without an NIH-approved Biosafety Assurance. (Section 6.1)

---

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

I support replacing the NIH Guidelines with risk-based biosafety oversight, and I write in support of that objective. My comments identify where the draft Policy does not yet achieve it.

1.1 The draft expands oversight of research NIH has already determined to be low risk, without explaining what changed.

NIH has described this effort as expanding oversight at the high-risk end while reducing burden for low-risk research. The second half has not been achieved. The draft brings within its scope several categories of research that are currently exempt under the NIH

Guidelines because the NIH Director affirmatively determined that they do not present a significant risk to health or the environment.

- **Propagation of recombinant plasmids in *Escherichia coli* K-12 host-vector systems**, exempt under Appendix C-II where the host carries no conjugation-proficient plasmid or generalized transducing phage and the insert derives from neither an RG3/RG4 or restricted agent nor a potent toxin. Under Section IV-3 the same work becomes "research with genetically modified RG1 biological agents" and requires approval before initiation.
- **Transfection of such a construct into a cultured mammalian cell line**, exempt since 59 FR 34472 (July 5, 1994) for recombinant molecules containing less than one-half of a eukaryotic viral genome propagated and maintained in tissue culture. Under the draft this is a genetically modified cell, which appears in Section IV-2 as full-committee work and, as a well-characterized cell line or a plasmid expressing a low-risk transgene, also in Section IV-3 as delegable. The Policy states no precedence rule, so institutions cannot determine which tier applies.
- **Breeding, transfer and use of BL1 transgenic rodents**, exempt under Appendices C-VII and C-VIII. In adopting the breeding exemption at 76 FR 3150 (January 19, 2011), NIH concluded that these experiments "do not pose an appreciable risk to human health or to the environment" and that "the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk." Generation of such lines is addressed under Section III-E-3, requiring registration at initiation but not prior approval. Section IV-3 would require prior approval for all of it.
- **Certain research with RG1 agents** not involving sequences from RG3, RG4 or restricted organisms, exempt under Appendices C-II through C-V.

The first two categories deserve particular attention because they are not marginal cases. Construction of expression plasmids and their introduction into cultured cells are the most frequently performed experimental activities in molecular biology and virology laboratories; a single project may generate dozens of constructs in a year. The draft does not state what must be registered — the backbone alone, the backbone with each insert, or each insert with each point mutation — and the answer determines whether this is an annual formality or a continuous bottleneck. Approvals also expire at three years and require de novo submission, so the burden recurs.

The draft offers no revised risk assessment for any of these categories. The cumulative-burden concern NIH identified in 2011 applies with greater force today, and with substantially greater force to routine cloning and transfection than to the rodent breeding it was written about. I ask that NIH either preserve these exemptions expressly or state what evidence supports a changed determination.

1.2 The Policy does not define the terms on which compliance depends.

The Policy is titled for research involving biohazards and does not define "biohazard." It also uses, without definition: *organism*, *transgenic*, *vector*, *GDMO*, *gene drive modified*

biological agent, *adventitious agent*, *incident*, *release*, *shedding*, *peptide*, and *potential risk to human health*. Several were also undefined in the NIH Guidelines, which makes this the right occasion to correct the problem rather than carry it forward.

"Organism" is the most consequential. It is used inconsistently and is not readily definable, and as written it leaves the relationship between Section IV-2 (genetically modified organisms) and Section IV-3 (transgenic organisms at BSL-1/ABSL-1) unresolvable, because the Policy never says how the two differ. I recommend replacing it throughout with the specific categories intended — bacteria, fungi, archaea, protists, viruses, animals — and stating expressly if there is a further category of concern, such as a biological agent produced through synthetic biology that does not fall within conventional taxonomy.

"Potential risk to human health" carries the entire scope boundary and is undefined. As written it could reach chemical, radiological or physical hazards already regulated by other federal agencies, which I do not believe NIH intends. NIH should define it as the potential to cause human disease or adverse health effects arising from the biological materials within the Policy's scope, state expressly that the Policy does not address non-biological hazards, and identify who applies the threshold and against what standard.

"Toxin" should be limited to substances of living biological origin and should exclude proteins and peptides whose primary adverse effect is an allergic or hypersensitivity response. As drafted, read together with Section IV-3's category for non-Select-Agent biological toxin proteins, the Policy reaches common laboratory reagents of biological origin.

1.3 The definition of genetic modification captures unintentional change and routine virology.

The definition includes stable alterations introduced by passaging, reassortment, or chemical or radiological means, and does not distinguish deliberate engineering from change that occurs incidentally. Serial passage of any virus in cell culture produces unintended genomic alterations; so do chemical mutagenesis, irradiation, and selection under drug pressure. Investigators performing entirely conventional work would be out of compliance immediately and without knowing it.

The definition also reaches nucleic acid molecules that "can be transcribed or translated," which includes transfection of a synthetic mRNA into a cell line. This produces an unexplained inversion: the draft removes deliberate administration of recombinant nucleic acids to human participants from the scope that Section III-C-1 of the Guidelines currently covers, while bringing transfection of the same material into cultured cells within scope. NIH should state the risk assessment supporting the conclusion that the in vitro use warrants review and the in vivo use does not.

I recommend the definition be rewritten to cover intentional, stable modification of the genome, with oversight keyed to the resulting phenotype, and that NIH address expressly how it applies to reverse genetics and viral rescue systems, including recovery of wild-type virus from cloned cDNA.

1.4 There is no review pathway for agents that lack a BMBL entry but are not emerging, novel or zoonotic.

Section IV-1 provides federal review for emerging, novel or zoonotic agents lacking an RG classification or minimum containment recommendation in the BMBL. The Policy provides nothing for the much larger set of agents that are none of those things and still have no entry. Human metapneumovirus, non-polio enteroviruses, human parainfluenza virus 5 and Sendai virus are long-established laboratory agents handled routinely at BSL-2, with no risk group in the NIH Guidelines and no BMBL agent summary statement.

Read literally, they fall into Section IV-1 and require NIH approval — an outcome that cannot be intended, given that wild-type RG3 and RG4 agents require only IBC review under Section IV-2. The same problem applies to human and animal microbiota: if research with common commensal genera requires federal review, it is not clear that an investigator can collect a human or animal specimen without entering noncompliance.

NIH should state expressly that local IBCs may perform the risk assessment and assign containment for agents in this category, reserving federal review for circumstances involving substantial uncertainty or potentially significant public or environmental consequence.

1.5 The Policy does not say who assigns risk groups.

Risk group assignment determines both the review tier and, for RG1, whether research is within scope at all — the Policy places wild-type RG1 agents outside its scope while also stating that absence from the RG2–RG4 listing does not imply classification as RG1. With Appendix B of the Guidelines retired, there is no authoritative source for these assignments and no stated authority to make them.

NIH should either publish and maintain a version-controlled list of RG1 through RG4 agents supplementing the BMBL, using Appendix B as its backbone and including RG1 agents expressly, or state in the Policy that the local IBC holds that authority. Participation by USDA, CDC and other agencies in a single list, including plant and agricultural considerations, would be valuable.

1.6 Section IV-2 operates as a catch-all with no stated boundary.

Section IV-2 requires IBC approval for initial submissions "not otherwise specified in other sections." A catch-all of that kind requires a corresponding section stating what falls outside the Policy. Institutions cannot operate from isolated bracketed notes, such as the one indicating that experiments with RG1 wild-type biological agents are not subject to the Policy. Without an express out-of-scope section, practice will vary widely between unintentional noncompliance and defensive over-review of work the Policy never meant to reach.

1.7 The relationship to other federal oversight must be stated precisely.

Section II provides that research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency once approvals or other

applicable clearances have been obtained." Section I-A-1 of the current Guidelines is narrower and clearer: another agency's approval may substitute for *NIH* review or approval. It does not displace institutional IBC oversight. The draft's broader language can be read to eliminate both, and it conflicts with the Policy's own clinical provisions, which require IBC approval in addition to all other regulatory approvals.

Concretely: an investigator registered with the Federal Select Agent Program to work with a wild-type RG4 agent needs to know whether IBC approval under Section IV-2 is still required. An investigator registered with FSAP to construct recombinant viruses in that backbone needs to know whether NIH and IBC approval are required in addition. And an institution needs to know whether an incident in high containment involving a registered Select Agent is reported to NIH and posted publicly, notwithstanding FSAP's own restrictions on security-sensitive information. NIH should state which Policy requirements survive another agency's jurisdiction, and whether approvals are sequential or concurrent.

(Implementation timing is addressed under Question 6.)

---

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs. local).

2.1 The tiered structure is the right approach, and delegated review should be made to work as intended.

The three-tier structure is a genuine improvement over the current framework, and the provision permitting delegated approval of lower-risk research — comparable to the designated member review long used by IACUCs — should meaningfully reduce the time the full committee spends on work that does not require its collective judgment. I also have no objection to bringing wild-type RG2, RG3 and RG4 biological agents within the Policy's scope. Institutions conducting that work already require IBC approval for it, and stating the requirement federally creates no new burden.

Two features of the delegated pathway undercut its purpose. First, requiring every delegated approval to be reported in full at the next convened meeting and included in publicly posted minutes recreates much of the workload the pathway exists to avoid. Institutions should be permitted to provide the committee with a concise approval log or aggregate report, with complete records retained and available for audit, and the Policy should define what role the full committee retains after a delegated approval has been granted.

Second, the Policy should make delegation under Section IV-3 optional rather than mandatory. Institutions differ in committee structure, meeting frequency and administrative capacity, and some will find full-committee review of a given category simpler than administering a delegated process for it. The Policy should also state expressly that delegated review is available for minor amendments — including amendments to research originally reviewed under Section IV-2 — and should distinguish administrative changes from changes requiring reassessment of risk.

Where delegated review is used, the Policy should specify a procedure: notice to all members of a pending review with access to the submission materials; a reasonable period, defined in written institutional procedures, within which any member may request full committee review; assignment of qualified, unconflicted member reviewers; agreement among multiple reviewers, with unresolved differences referred to the full committee; and communication of the approval to the committee for inclusion in its records.

2.2 The Policy provides no rule for resolving overlapping categories.

Sections IV-2 and IV-3 overlap substantially. Genetically modified cells, viruses and organisms appear in Section IV-2 as full-committee work, while several subsets of the same research — well-characterized cell lines, genetically modified RG1 agents, plasmids and non-integrating vectors expressing low-risk transgenes — appear in Section IV-3 as delegable. Nothing in the Policy states which controls. The same construct transfected into the same cell line can be classified in either tier depending on which sentence the reviewer reads first.

The final Policy should state expressly that the most specific applicable category controls, and should include a review-pathway decision table with worked examples spanning full committee review, delegated review, registration, exemption and NIH review. The table should resolve routine cases that will otherwise be decided inconsistently across institutions: transfection of an established cell line, use of a previously edited cell line, a change in personnel, and a change in laboratory room. A room change should not be treated as administrative without first assessing its containment implications. The Policy should also state how de novo renewals are categorized.

2.3 Several categories are placed in tiers disproportionate to their risk.

The categories identified in Section 1.1 above are not merely formerly exempt; they are placed at review levels that do not correspond to any articulated biosafety concern. The Policy does not describe how oversight of this research increases biosafety or biosecurity, and in several cases the administrative burden is substantial while the risk is negligible.

Genetically modified cells, viruses and organisms (Section IV-2). This category is misplaced and internally inconsistent. Genetic modification of cells presents very low biosafety risk absent introduction of nucleic acids from RG3 or RG4 agents or sequences encoding toxins, and such work should be at most within Section IV-3, if not exempt. The category also contains terms that are undefined or poorly defined and that conflict with other categories: as written “organism” appears to include animals notwithstanding the separate transgenic category in Section IV-3; “vector” does not distinguish viral vectors from arthropod disease vectors; and “gene drive modified biological agent” cannot be reconciled with the Policy’s own definition of biological agent, while its relationship to the undefined acronym GDMO is unstated.

I recommend this category be removed or extensively rewritten as follows:

- The definition of genetic modification should be limited to intentional stable alterations of the genome, as described in Section 1.3 above. Definitions for

organism, *vector*, *GDMO* and *gene drive modified biological agent* must be added to the Policy or the terms removed.

- Research with genetically modified RG3 and RG4 biological agents should require IBC approval.
- Research with genetically modified RG2 biological agents should be eligible for delegated approval.
- Research with gene drive modified organisms should require IBC approval.
- Review of research with genetically modified cells should depend on the modification, with pathways ranging from IBC approval through delegated approval to complete exemption from the Policy.

Research with genetically modified RG1 biological agents (Section IV-3). Certain research with RG1 agents not involving DNA from RG3, RG4 or restricted organisms is exempt under Appendices C-II through C-V, having been determined by the NIH Director not to present a significant risk to health or the environment. This category contradicts that determination without explanation. I recommend it be removed.

Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes (Section IV-3). This research is of low biosafety and biosecurity risk and the Policy does not describe how regulating it advances either. Investigators generate plasmids continuously, and requiring prior approval for them will produce a severe bottleneck and extensive unintentional noncompliance. The Policy also fails to state the extent of what must be registered — the backbone alone, the backbone with each gene to be inserted, or each gene with each mutation of that gene. I recommend this category be removed.

Research with well-characterized cell lines (Section IV-3). The Policy does not identify the biosafety concern this category addresses, nor what must be registered: that an investigator works with cell lines at all, each individual line, or whether an entire catalog may be approved at once. Registration of this work will produce extensive unintentional noncompliance and crippling administrative burden for investigators and committees alike, with no corresponding benefit. I recommend this category be removed.

Research conducted with transgenic organisms at BSL-1/ABSL-1 (Section IV-3). For the reasons given in Section 1.1, work with transgenic rodents that may be housed at ABSL-1 should not require IBC approval. I recognize that research with some transgenic animals may not yet have accumulated a comparable safety record and should continue to require approval before initiation. NIH should also consider whether transgenic fruit flies and zebrafish warrant exemption on the strength of their own track record. I recommend this category be rewritten as: *Research conducted with transgenic animals, other than transgenic rodents, fruit flies and zebrafish, that may be housed at minimum BSL-1/ABSL-1/ACL-1.* Consistent with Section 1.2, "organism" should be replaced with "animal" in this category.

Research with biological toxin proteins not on the Select Agent list (Section IV-3). Under the Policy's definition of toxin, this category reaches food and animal allergens and other common reagents of biological origin, which cannot be the intent. There is also a conflict between the category's wording and the definition itself that makes the scope

difficult to determine. Work with toxins is in many institutions already overseen by a chemical safety committee, and additional committee review will not increase safety. I recommend this category be removed. If it is retained, it should be rewritten as: *Research with biological toxin proteins with an LD_{50} in vertebrates of less than 100 micrograms per kilogram of body weight* — and the Policy should include a list of toxins classified under it, using the LD_{50} classification currently available from NIH OSP under Appendix F-1 of the Guidelines as its backbone.

Institutions should additionally be permitted to clear work in any of these categories through a documented internal screening process where that process determines the work presents minimal biosafety risk, and should retain authority to elevate work to a higher tier when local circumstances warrant.

2.4 Primary cells "that may be contaminated by adventitious agents" sits at the wrong tier and rests on an undefined term.

Section IV-2 requires full IBC approval for research with primary cells that may be contaminated by adventitious agents. The Policy does not define "adventitious agent," so institutions cannot determine what is covered. Read literally, "may be contaminated" reaches nearly all primary cell work, including cells from low-risk sources, which conflicts directly with Section IV-3's treatment of well-characterized cell lines as delegable.

The tier assignment is also inverted. Research with material that *may* contain a contaminant requires full committee review, while research with a *known* RG2 agent requires only delegated review. For clinical specimens suspected to contain higher-consequence pathogens, the BMBL recommends BSL-2 practices, containment equipment and facilities for routine handling of specimens of human or animal origin. The Policy should harmonize the level of review accordingly.

I recommend this category be removed. If it is retained: "adventitious agent" must be defined — for example, as an unintended biological agent present in cells, tissues, animals or reagents that was not deliberately introduced and is not part of the planned research; "may be contaminated" should be replaced with risk-based criteria tied to the source and screening status of the material, such as unscreened primary human or non-human primate cells; the work should not require approval where the institution complies with the OSHA Bloodborne Pathogens Standard or its equivalent; and in no case should it require more than delegated review under Section IV-3. If the intent is instead to reach primary cells potentially contaminated by any unknown biohazard, such as field samples, that should be stated and defined.

2.5 Federal review as drafted leaves no path to study a newly identified agent.

Section IV-1 requires NIH and IBC approval for research involving emerging, novel or zoonotic agents for which an RG classification or minimum containment recommendation is not available in the BMBL. For investigators whose research involves identifying previously unrecognized agents, this creates a closed loop. Once an agent is identified and found to have no assigned risk group and no BMBL recommendation, the research requires NIH approval — but without the ability to work with the agent, the investigator cannot

generate the data on which NIH would base its risk assessment. The Policy offers no route out of this.

The practical consequence is that this work will not be done in the United States. Investigators will not undertake projects that cannot be initiated, and agent discovery and characterization will shift to institutions in other countries, leaving US researchers dependent on others for the foundational characterization of agents that may later matter a great deal.

The trigger is also drawn far more broadly than the category of genuinely high-consequence uncertainty it appears aimed at. As written it captures many uncommon agents currently handled routinely at BSL-1 and BSL-2, including organisms recovered during environmental screens, and — as described in Section 1.4 — well-established agents that are simply absent from the BMBL.

I recommend the Policy describe a clear approval pathway permitting investigators to generate the data required for a risk assessment, with that review performed by the local IBC. More generally, NIH should consolidate the overlapping petition provisions, define narrowly when an emerging, novel, zoonotic or unlisted agent requires federal review, include an explicit decision rule for the case where reference information is absent, permit qualified IBCs to make interim or final containment determinations for well-characterized agents, and reserve federal preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequence.

2.6 "Emerging agent" is not a stable category and the Policy does not say who applies it.

The Policy does not state who determines that an agent is emerging. If that determination rests with the local IBC, the Policy should say so. If it does not, NIH should issue rapid dissemination notices identifying emerging agents so that institutions can avoid noncompliance with a classification they had no way to anticipate.

The Policy also does not describe how an agent ceases to be emerging. Does the designation persist until NIH first reviews the agent under Section IV-1, until a risk group is assigned, or until the agent appears in the next edition of the BMBL? Nor is it clear whether the definition reaches a well-characterized agent that exhibits a change in pathogenicity or transmission: had this Policy been in effect, it is not evident whether the recent outbreaks of Zika virus, mpox virus or Andes virus would have qualified, or whether the designation would attach to the agent or only to the specific strain. Applied today, it is not clear which agents would qualify — highly pathogenic avian influenza H5N1, or SARS-CoV-2.

These are not hypothetical distinctions. They determine whether an institution must obtain federal approval before beginning work, and an institution that guesses wrong is noncompliant.

2.7 Recombinant agents constructed within a family should be reviewable by the IBC.

The Policy's definition of novel agent captures recombinant constructs assembled from parental agents that already have assigned risk groups or recommended biosafety levels. Investigators generate such constructs routinely to study the basic biology of these agents

— exchanging a gene between two members of the same viral family, for instance, where both parents are well characterized and the containment appropriate to each is already established.

Research of this kind does not fit the Policy's own conception of higher-risk work requiring federal review. These experiments currently fall within Section III-D of the NIH Guidelines, which demonstrates that for decades NIH has determined they can be reviewed by the local IBC. It would also be inconsistent to require federal approval here while Section IV-2 assigns research with wild-type RG3 and RG4 agents to local review.

I recommend that the Policy permit IBC review of research involving recombinant agents generated within the same family for viruses, or the same genus for bacteria and fungi, and of research involving recombinant agents where the natural source agents have assigned risk groups or recommended biosafety levels.

2.8 Federal review requires a stated reviewer, published determinations and a response timeline.

Who reviews. The Policy replaces two former categories — research requiring NIH Director approval under Section III-A of the Guidelines and research requiring NIH OSP approval under Section III-B — with a single category requiring "NIH approval," without stating which office or person performs it. Institutions can reasonably expect materially different response times from the Director and from OSP, and OSP is staffed with subject matter experts across the range of biomedical science in a way no single official can be. The Policy should state, within the responsibilities of NIH in Section III-D, who is responsible for each duty assigned to NIH, and should publish submission checklists, completeness criteria, response targets and escalation routes.

Determinations must be reusable. The Policy implies a workflow for lowering containment — an institution submits an initial request for wild-type or genetically modified RG3 or RG4 agents; NIH determines whether lower containment is appropriate; NIH publishes approved determinations; subsequent research with those agents may thereafter be approved by the IBC alone. That workflow should be stated expressly, including an unambiguous statement that once NIH has published a determination, other institutions need not obtain their own approval. This would correct a significant limitation of the current system, under which approvals extend only to a single investigator at a single institution, requiring other investigators at the same institution to seek the same determination again.

NIH should publish all containment determinations — agent, modification, approved containment and rationale — in a searchable public resource that other institutions may rely upon, not only the RG3 and RG4 lower-containment determinations Section III-D currently commits to publishing. Section III-D makes no equivalent commitment for emerging or novel agents, and it should. The Policy should state the method and minimum frequency of publication, define what constitutes substantial equivalence and which deviations are permissible, identify who determines whether a prior determination applies, and state what documentation is expected. It should also set a target response timeline — 30 calendar days would be reasonable — rather than relying on the word "timely."

Finally, the Policy should state how much information accompanies a published determination, and specifically whether publication would include security-sensitive information or unpublished data.

Risk group and containment determinations should apply broadly. Determinations of risk group and recommended biosafety level should apply to all investigators and all institutions subject to the Policy, not to the requesting investigator alone. Differences in recommended containment arising from geography, climate or research conducted outside the United States should be accounted for in implementing this change.

2.9 The three-year approval ceiling imposes burden without a stated safety benefit.

The Policy provides that approval "should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required." It does not describe how biosafety or biosecurity is improved by this limit. Research projects continue over years and decades, and they rarely incorporate changes that significantly alter the original risk assessment; those that do are already captured by the requirement to obtain approval for significant changes before implementation.

Requiring de novo submission on a fixed three-year cycle will substantially increase administrative burden for both investigators and committees for little or no gain in safety. I recommend the requirement be removed, and that the Policy instead provide for risk-based continuing review between renewals. If the requirement is retained, the Policy should expressly permit grandfathering of previously approved registrations carrying approval periods longer than three years.

---

3. Continued utility of Risk Groups as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels outlined in the BMBL.

3.1 Risk Groups retain utility as hazard descriptors, but should not independently determine containment or review level.

Risk Groups remain valuable tools for initial hazard communication and agent characterization, and I do not recommend that NIH abandon them. They should not, however, independently dictate either the containment level at which research is conducted or the tier at which it is reviewed. The final Policy must preserve site-specific and experiment-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities and available mitigations.

This is consistent with the draft's own Section V-E, which acknowledges that Risk Groups and Biosafety Levels are related but non-equivalent concepts. A Risk Group describes the characteristics of an agent; a Biosafety Level describes a set of containment practices, equipment and facilities. The problem is that other provisions of the Policy do not follow Section V-E's lead, and several of them treat the two as interchangeable.

3.2 Risk Groups cannot bear the structural weight the Policy places on them.

Section IV keys multiple oversight categories directly to Risk Group — research with RG3 or RG4 wild-type agents to Section IV-2, RG2 wild-type agents and genetically modified RG1 agents to Section IV-3, and lower-containment requests to Section IV-1 depending on the agent's Risk Group. A classification system used this way must be precise, authoritative and well matched to the decision it is being asked to drive. Risk Groups are not, for several reasons:

- **They describe risk to a healthy adult in the community.** Section V-A states that Risk Groups reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some personnel are more susceptible because of medications, immune status or pregnancy.
- **They reflect community exposure, not laboratory conditions.** The concentrations, volumes and manipulations used in a laboratory differ greatly from any exposure occurring in the community or the environment.
- **They provide no baseline for novel constructs.** Recombinant and synthetic nucleic acid constructs do not exist in the community until they have been made and studied in a laboratory, which is the purpose of the laboratory. There is nothing for a community-based classification to describe.
- **They cover only human etiologic agents.** The Policy's conception of biohazards is broader than agents that cause human disease, so Risk Group cannot serve as the general basis for classifying biohazardous material.
- **They are routinely misinterpreted.** Investigators and federal agencies alike treat the Risk Group number as a containment requirement. This is a safety problem in both directions: it invites containment decisions that are not grounded in the actual experiment, and it substitutes a label for the assessment that should be performed.

Retained as one input to the first step of a risk assessment — characterizing the hazard — Risk Groups are useful. Used as the trigger for an oversight tier, they import all of the limitations above into a compliance determination.

3.3 The petition provision contains a condition that cannot be satisfied.

The IBC Functions provision directs the committee to petition NIH to determine the minimum biocontainment level for emerging, novel or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and prohibits IBC approval of such research until authorized by NIH and other applicable entities. This provision has two defects.

First, it treats "RG classification" and "containment level" as alternative items that might be found in the BMBL, which contradicts Section V-E's own statement that the two are non-equivalent. NIH should use these terms consistently throughout the Policy.

Second, and more consequentially: **the BMBL does not assign Risk Groups.** It provides agent summary statements with recommended Biosafety Levels. A condition framed as the absence of an RG classification "in the BMBL" can never be met, because no RG

classification is available there for any agent. As drafted, the provision either applies to every agent or to none, depending on how a reader resolves an error in its premise. This language requires correction.

3.4 The petition requirement is undefined as to who else must approve, and overbroad as to what it reaches.

The provision conditions IBC approval on authorization by NIH "and any other applicable Federal, State, or local entities." That phrase introduces substantial ambiguity. NIH should identify which entities are contemplated, specify whether their approvals are sequential or concurrent, state how coordination is to occur, and establish a resolution pathway for the case where determinations conflict. An institution cannot comply with a requirement to obtain approvals from an unspecified set of authorities.

The requirement is also broader than its apparent purpose. As written it can be read to apply to non-pathogenic genetically modified constructs and to benign RG1 organisms that are not specifically named in the BMBL — which is to say, most of them. NIH should state expressly that unlisted, non-pathogenic RG1 agents do not require federal petitioning. Without that clarification, the petition pathway will accumulate a backlog of submissions concerning agents that present no meaningful hazard, at the expense of the submissions that warrant federal attention.

3.5 Because Section IV depends on Risk Group assignments, the absence of an authoritative source is a structural problem.

As described in Section 1.5, Risk Group assignments have been removed from the former Appendix B of the Guidelines and do not appear in the BMBL, while the Policy continues to assign oversight tiers by Risk Group and places wild-type RG1 agents outside its scope entirely. There is presently no authoritative source for the classification on which the entire Section IV structure depends.

NIH should provide an authoritative, version-controlled federal repository of Risk Group assignments, or publish clear objective criteria by which institutions are to assign Risk Groups to non-recombinant agents, or state expressly that the local IBC holds that authority. Absent one of these, institutions will reach conflicting conclusions about the same agent, and the national consistency the Policy is intended to produce will not be achieved. Where NIH or an IBC makes a containment determination, it should apply to all investigators and institutions subject to the Policy rather than to the requesting investigator alone; Section 2.8 above addresses publication and reuse of those determinations.

The Policy should also provide a transition rule for research already under IBC approval. Many institutions have agents in active use that have no Risk Group assignment and no BMBL agent summary statement, for which the local committee has assigned a containment level based on a documented risk assessment and the published literature. NIH should state whether those determinations remain valid, whether they must be submitted for federal confirmation, and on what schedule — and it should not require that ongoing work stop pending that process.

3.6 Rigid containment minima conflict with the performance-based risk assessment the Policy otherwise requires.

The Policy requires experiment-specific risk assessment in Sections V-A through V-E, then imposes fixed containment prescriptions that override it in particular cases. Two examples warrant revision.

A universal minimum of BSL-2 for gene drive modified organisms does not map onto the specialized containment systems in which much of this work is appropriately performed — arthropod containment levels, greenhouse standards, and aquatic facilities each describe containment in terms that do not correspond to laboratory biosafety levels. NIH should permit equivalent risk-based containment modalities and issue specialized guidance for these systems rather than requiring institutions to translate an ill-fitting minimum.

Containment requirements for influenza constructs should specify the phenotypic traits, host range and pathogenicity markers that warrant enhanced containment, rather than sweeping in constructs on the basis of raw genomic segment proportions. A requirement keyed to the proportion of a genome drawn from a particular source captures constructs whose phenotype does not warrant the containment imposed, and may fail to capture constructs whose phenotype does.

3.7 Risk assessment guidance would do more to improve consistency than classification would.

If Risk Groups are to serve as one input to risk assessment rather than as a determinant of oversight, the Policy and its implementation materials should give institutions a usable method. I recommend NIH:

- State plainly how the Policy's controlling requirements and its reference guidance interact, and how differences between them are resolved.
- Permit qualified staff to support risk assessments while investigators retain their own responsibilities and the IBC independently evaluates the conclusions reached.
- Provide a concise documentation format covering likelihood, severity, exposure pathways, uncertainty, controls, residual risk and decision authority — so that an assessment can be reviewed, compared and audited.
- Publish worked examples for the categories institutions find hardest: attenuated and opportunistic agents; toxin potency, dose and form; prions and self-aggregating proteins; and validated inactivation.
- Address how short, unknown, proprietary and computationally designed sequences are to be assessed, including how encoded function, expected phenotype and residual uncertainty bear on the containment decision.
- Distinguish functional gene drives from components, split systems and intermediates, which present materially different risks and should not be treated identically.
- Clarify how influenza strain, segment and pseudotype combinations are assessed, and when a previous containment determination remains applicable to a related construct.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).

No comments at this time.

5. Comments on the Draft Incident Reporting and Draft Meeting Minutes Templates.

5.1 The effort to establish clearer federal thresholds is welcome and should be carried further.

I support the draft's effort to identify specific categories of events warranting immediate notification and follow-up reporting. Clear thresholds improve consistency across institutions and allow NIH to focus its attention on events with genuine potential public health or community significance.

The definition of a reportable incident should be refined, and the thresholds stated more precisely, so that a risk-based approach is applied consistently rather than interpreted institution by institution. The sections below identify where the current language does not yet permit that.

5.2 The Policy must define the terms on which reporting obligations depend.

The reporting provisions turn on terms the Policy does not define: *incident*, *release*, *potential exposure*, *minor spill*, *improper disposition*, and the distinction between basic first aid and agent-specific medical treatment. An institution cannot build a compliant reporting workflow around undefined triggers, and the result will be inconsistent practice and unintentional noncompliance rather than better information reaching NIH.

I recommend NIH adopt the following definitions in Section II:

- **Incident:** A confirmed theft, loss, or release — such as an occupational exposure or a release outside the defined biocontainment barriers — of biological material under the scope of the Policy.
- **Release (loss of containment or occupational exposure):** A failure in biosafety practice and/or equipment such that there is occupational exposure of the person or persons working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
- **Potential exposure:** An event occurring in the active presence of a biohazard where primary barriers or personal protective equipment were breached, creating a credible exposure pathway. Equipment or PPE failures occurring in the absence of active biohazardous agents are not potential exposures.

- **Minor spill:** A defined term, replacing the current formulation that minor spills "generally do not need to be reported." Subjective qualifiers such as "generally" should be removed throughout.

NIH should also align "medical treatment" explicitly with the OSHA standard — care beyond basic first aid — and state that precautionary, non-specific post-exposure prophylaxis and routine medical consultation do not constitute agent-specific treatment triggering 24-hour federal reporting. The Policy should additionally clarify how precautionary medical evaluation, prophylaxis, potential adventitious agents, and mixed or uncertain exposures bear on reportability.

5.3 The Policy should not treat maintained containment as a potential release.

The draft requires reporting of "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly." This requirement is internally contradictory. Containment at higher biosafety levels is built on layered engineering barriers precisely so that the failure of one component does not result in the escape of biological material. When redundant systems function properly and containment is maintained, no release has occurred and none was imminent; characterizing the event as a potential release describes the system working as designed as though it had failed.

Read literally, the provision makes a spill fully contained within a biosafety cabinet a reportable event. At BSL-3, a spill outside primary containment is a breach requiring room evacuation and air clearance, and directional airflow and exhaust filtration are what prevent escape from the room — these are meaningful distinctions that the current language collapses.

I recommend NIH remove this phrasing and instead:

- Anchor "release" to containment boundaries, as defined in Section 5.2 above.
- Calibrate reporting expectations to the containment level, recognizing that higher containment incorporates redundant secondary barriers that prevent environmental dissemination even during procedural disruption.
- State that PPE or equipment failures occurring without exposure to an active agent are not reportable incidents.
- Clarify whether any event occurring at BSL-3 or BSL-4 is reportable regardless of whether it bears on biohazard containment, and distinguish equipment malfunctions where backup containment was maintained from events where containment was actually compromised.

5.4 Administrative noncompliance should be distinguished from substantive noncompliance.

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories, with no distinction drawn between kinds of noncompliance. Late paperwork, a minor recordkeeping error or a missed administrative deadline are not the same as initiating research without approval or lowering containment without authorization, and they should not be reported on the same timeline.

I recommend the Policy distinguish administrative noncompliance from substantive biosafety noncompliance, identify which violations are reportable regardless of risk and which are eligible for internal correction, and state plainly that administrative noncompliance and low-risk items never require 24-hour reporting. "Significant violations" should be defined as noncompliance that directly compromises containment or involves initiation of unapproved high-consequence research.

5.5 The reporting workflow needs mechanics institutions can actually implement.

The Policy establishes a 24-hour notification and a 30-day report without specifying how either is operated. I recommend NIH address the following, ideally in the form of a reporting decision table accompanying the template:

- Who receives the initial report, and — critically — whose awareness starts the 24-hour clock. An institution cannot demonstrate timely notification without knowing when the clock began.
- The minimum information an initial notification must contain, and how uncertainty is to be handled when the facts are not yet established.
- When the 30-day period begins, and whether an interim report is permitted where the investigation remains incomplete at that point.
- That investigations may be conducted jointly by qualified biosafety, occupational health, clinical and veterinary personnel, with escalation to the IBC based on risk, recurrence or unresolved concerns, while preserving each body's own reporting duties. Qualified response personnel should be able to investigate and take immediate protective action without waiting for a convened meeting.

Paired worked examples would resolve most of the ambiguity at once: a contained and disinfected spill with no exposure against an event creating a credible exposure or release; an equipment malfunction with backup containment maintained against an actual containment failure; and an administrative lapse against unauthorized initiation of work. In each pairing, NIH should identify the specific facts that change the reporting pathway.

5.6 Regulatory reporting should be decoupled from public website posting.

Section III-B requires institutions to post all incident reports on a public-facing website, including reports of lower-risk incidents that are managed institutionally and are never reported to NIH. The Draft Incident Reporting Template requires identification of the Principal Investigator and does not permit redaction of the PI's name, expressly excluding the PI from the exemption that allows other involved individuals to remain unidentified, on the rationale that information available from public sources may not be redacted. I support appropriate transparency about significant biosafety incidents and institutional responses, but the disclosure requirements as drafted produce four consequences that work against the Policy's own objectives.

Personnel can be identified from posted reports. Reports containing the PI's name, the agent, the grant number and the facility location frequently provide enough detail to identify the individuals involved in an incident, even where those individuals are nominally

unidentified. The information required for public posting may therefore disclose what amounts to individual medical information, with attendant legal exposure for the institution.

Identification creates personal safety risk. Linking named investigators to specific agents, funding and facility locations exposes researchers and animal care personnel to harassment, threats and targeted cyber-attacks. This concern is most acute in animal research and in other areas that have historically attracted targeting, and it applies equally to the continuously updated IBC rosters and the contact information for IBC chairs, Biological Safety Officers and committee contacts contemplated by the Biosafety Assurance.

Aggregated postings constitute a research security exposure. Publicly posted incident reports and committee minutes accumulate over time and across institutions. Taken together they would reveal which agents institutions work with, the direction of unpublished work in individual laboratories, the locations of high-containment research, and which facilities have experienced failures of equipment, training or procedure. Automated collection tools can assemble these records into a map of national high-consequence research capability. That outcome is difficult to reconcile with federal research security policy and with the Federal Select Agent Program's own restrictions on security-sensitive information. NIH should coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, before establishing public disclosure requirements.

Posting suppresses the reporting the Policy wants to encourage. Requiring minor, fully mitigated events to appear in public view discourages internal reporting of near-misses and borderline events, out of concern for public reaction and institutional reputation. The Policy elsewhere seeks to build a safety-learning system; this provision works directly against it.

NIH should calibrate disclosure to the significance and potential public health consequence of the incident. For lower-risk incidents that do not meet federal reporting thresholds, de-identified reports, standardized summaries or aggregated reporting would provide meaningful transparency and genuine opportunity for shared learning. NIH should also state the public interest or biosafety rationale for requiring PI identification in individual reports, and consider whether that identification contributes anything to understanding or preventing incidents. As a general matter, routine public disclosure should not extend to investigator names, grant or internal project numbers, sensitive animal research information, select agent and toxin information, proprietary materials and research outcomes, identifying facility information, or other details that could compromise safety, security or personnel protection.

The better route to transparency is aggregate reporting. NIH can meet its transparency objectives by publishing aggregated, de-identified incident data — an annual incident summary with trends, contributing factors and lessons learned — and through the National Biosafety Data and Safety Analysis Center, while full records remain available to NIH and other authorized reviewers to support investigation of laboratory-acquired infections and other public health needs. A confidential national reporting system of this kind is only

useful if its boundaries are clearly drawn and if institutions and investigators trust that voluntary submissions will not be used for enforcement. NIH should state expressly how confidential voluntary reporting to the NBDSAC interacts with mandatory reporting and public posting, and identify the limits of that confidentiality, so institutions can participate without uncertainty about their disclosure obligations.

5.7 If public posting is retained, redaction standards and deadlines must be specified.

Should NIH retain a public posting requirement, two elements are presently missing.

First, redaction. The Policy should permit redaction of PI names, grant identifiers, and information necessary to protect proprietary and security-sensitive material. The current formulation of "appropriate and allowable" redactions should be replaced with "specific and allowed" redactions, accompanied by standardized examples that identify what institutions may withhold on safety or security grounds. Because state public-records laws vary and may constrain what an institution is permitted to withhold, NIH guidance should distinguish the federal posting and redaction standard from any additional disclosure obligations imposed by state law.

Second, timing. The Policy ties posting to NIH's final response without defining when that response occurs. An institution cannot be held to a posting deadline that depends on an open-ended federal review. NIH should establish a defined endpoint for its final response, and state what an institution is to do if that endpoint passes without one.

5.8 The minutes template should specify content elements rather than a format.

Institutions differ in meeting structure, recordkeeping practice, information systems, and use of software platforms that may generate meeting records or summaries automatically. A mandated template will require many institutions to maintain parallel records — one set for operations and one for compliance — without improving the information NIH or the public receives.

NIH should instead require the specific content elements needed to support transparency and accountability: review category, approval decision, containment level, and any required conditions of approval. A content-based requirement allows institutions to use their existing processes and systems while ensuring the required information is consistently documented and made available, subject to appropriate protection of sensitive information. The same flexibility should apply to the documentation format of both public meeting minutes and incident reports.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

6.1 A six-month effective date is not implementable; the Policy needs at least 24 months and a phased transition.

The proposed six-month effective date is not realistic given the scope of what institutions must accomplish before covered research may continue. Within that window an institution would need to inventory all newly covered research, obtain an approved Biosafety Assurance, revise institutional policies, redesign electronic submission and records systems, build public-facing posting processes, establish redaction standards, revise incident response and reporting workflows, train investigators and committee members on requirements that do not yet exist in final form, secure institutional approvals and funding for all of it, and in some cases establish an entirely new committee.

The Assurance requirement compounds the problem. No covered research may proceed after the effective date without a written Biosafety Assurance approved by NIH. That places every institution's entire covered portfolio behind a single federal approval, submitted on roughly the same schedule as every other institution's. It is not evident that NIH will have the staff to review and approve several hundred Assurances within six months of publication, and the consequence of a backlog falls on research that is already underway and already approved locally.

I recommend NIH provide at least 24 months after publication of both the final Policy and the complete implementation materials, structured as follows:

- **Phased milestones** for inventory of covered research, staffing, training, systems changes, Assurance approval, and conversion of existing registrations — so that institutions can sequence the work rather than attempt all of it simultaneously.
- **Provisional or deemed assurance mechanisms** that prevent interruption of ongoing research where federal review is incomplete through no fault of the institution.
- **Staged conversion of existing approvals.** Registrations approved under the NIH Guidelines should be permitted to convert at their next significant amendment or scheduled renewal rather than all at once, with appropriate safeguards and with priority given to higher-risk work.
- **Preservation of staggered renewal cycles.** Institutions have deliberately distributed renewal dates across the year. A conversion process that collapses them into a single cohort would create a backlog that persists for years and would degrade review quality for the work that most needs attention.

6.2 The templates and tools should be piloted before they become mandatory.

NIH should pilot the Biosafety Assurance, meeting minutes, incident reporting, risk assessment and delegated review tools with institutions representing a range of sizes, missions, research portfolios and program maturity. The findings should be published and

used to refine the instruments for burden, clarity and usability before compliance with them is required.

This is worth the time it costs. Several of the drafting problems identified elsewhere in these comments — the reference to Risk Group classifications in the BMBL, the requirement to report failures where redundant systems maintained containment, the absence of a precedence rule between review tiers — are the kind of issue that surfaces immediately when a practitioner attempts to apply a document to a real submission, and that is difficult to see when reading it in the abstract.

6.3 The implementation resource set should be complete and available before the effective date.

The resources institutions will need include: a Biosafety Assurance template; model institutional policies; decision trees for determining review pathway and scope; risk assessment forms with worked examples; training material directed separately at committee members, biosafety staff, principal investigators and laboratory personnel; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database as described in Sections 1.5 and 2.8 above; and guidance addressing external, shared and consortium committee models.

There is also a transition-integrity question that the resource list should resolve. The NIH Guidelines carry substantial operative detail in their sections and appendices — containment specifications, laboratory practice requirements, training expectations, animal research provisions and occupational health requirements that are referenced by, but not reproduced in, the draft Policy. When the Guidelines are retired, those requirements need to land somewhere. NIH has indicated that implementation resources will draw on existing provisions, and I support preserving these risk-based protections. NIH should identify which of them remain mandatory, state whether any differ from the current Guidelines, name the authoritative document in which each will reside, and issue those materials concurrently with the final Policy and sufficiently in advance of the effective date for institutions to assess and demonstrate compliance.

6.4 NIH should publish a crosswalk between the final Policy and the requirements it replaces or overlaps.

Institutions have years of registrations, standard operating procedures, training materials and committee practice built on the section structure of the NIH Guidelines. Retiring that document without a mapping leaves every institution to independently determine which provision of the new Policy corresponds to which provision of the old one — and they will reach different conclusions about the same question.

I recommend NIH publish a crosswalk between the final Policy, the NIH Guidelines it replaces, and other federal requirements governing research with biohazards, identifying for each area which framework governs, who owns the review, what information is shared between oversight bodies, and the applicable effective dates. This would reduce duplicative review and would give a concrete answer to the jurisdictional question raised in Section 1.7 above, rather than leaving it to be resolved institution by institution and case by case.

6.5 Two areas where additional guidance is specifically needed.

Prions and self-aggregating proteins. The Policy's definition limits this category to misfolded forms of proteins that self-propagate and cause neurodegenerative disease. That definition is reasonable, but applying it at the bench requires judgment the Policy does not support. NIH should provide practical examples and risk assessment guidance, including explicit direction on distinguishing in-scope materials from ordinary physiological protein aggregation. Without it, institutions will either over-report routine protein biochemistry or fail to identify work that genuinely falls within the category.

Computational and AI-assisted work. NIH should clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. This is a distinct question from the risk assessment of physical agents that were designed using computational or AI tools, and the two should be addressed separately. For the latter, NIH should provide practical guidance on evaluating the resulting biological hazards and on recognizing when a committee needs expertise it does not have.

6.6 The Policy should not operate as an unfunded mandate.

The draft substantially expands institutional obligations — scope of covered research, volume of review, documentation, public posting, assurance and reporting — without addressing how that work is to be resourced. Other federal regulatory agencies are required to assess the financial impact of policy changes before imposing them. In the absence of such an assessment here, NIH should address compliance cost directly.

I recommend NIH consider dedicated biosafety funding supplements; explicit statements of allowability for appropriate biosafety costs in direct or indirect cost structures; workforce development programs; shared training resources; and implementation support targeted to smaller and less-resourced institutions, for which the proportional burden of this Policy is greatest. Estimates of the additional effort NIH anticipates institutions will require would also allow institutional leadership to plan and budget rather than absorb the requirement unprepared.

6.7 The Policy should expressly permit flexible institutional arrangements.

The final Policy should state clearly that shared or consortium committees, external committee services and mutual-aid arrangements are permitted. Requirements for unaffiliated members and for specialized expertise should be flexible enough to remain workable in small, rural or geographically isolated communities, and in communities dominated by a single institution where genuinely unaffiliated members are difficult to recruit — while still preserving meaningful independent input. Guidance addressing how these arrangements satisfy the Policy's requirements should be part of the implementation resource set.

Closing

I appreciate the opportunity to comment on this draft, and I want to be clear that the volume of comment above reflects engagement with the proposal rather than opposition to it. The modernization NIH has undertaken is overdue, and the structural choices in the draft — tiered review calibrated to risk, delegated approval for lower-risk work, scope organized around hazard rather than technique — are sound. What the draft needs is precision: definitions that allow an investigator to determine what applies to the work in front of them, review tiers that correspond to actual risk, and an implementation period long enough that institutions can comply rather than improvise.

The concerns raised in these comments, and those raised by the biosafety and research communities more broadly, indicate that the draft cannot be implemented in its present form. I respectfully request that NIH revise the Policy and publish an additional draft for public comment before final issuance, and I would welcome the opportunity to review and comment on that revision.

Thank you for your consideration.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): bacteriology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As a research microbiologist at an academic institution, I appreciate the thought that went into updating this policy, but I would like to see more clarity around its exact boundaries. As currently written, the term 'biohazard' is not explicitly defined, which leaves uncertainty about whether risks to animal health, plant health, agriculture, or the environment are inside or outside of scope. It would be helpful if the NIH could provide clear definitions and consistent terminology for 'biological agents' and 'biomedical research' so that universities — places where NIH and non-NIH funded environmental or microbiome studies happen side-by-side—know exactly when this policy applies. Additionally, providing clear rules on how existing local IBC approvals for agents without official Risk Group assignments will be transitioned would prevent significant administrative confusion.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): One of the main stated objectives of this modernization effort is to expand oversight of higher-risk activities while simultaneously reducing unnecessary burden for low-risk research. While the draft successfully broadens oversight to include many biological hazards beyond recombinant and synthetic nucleic acid technologies, it is less clear how the proposal reduces burden for lower-risk activities. For example, while RG1 wild-type agents are excluded from review, RG1 derivatives and other low-risk materials such as plasmids and well-characterized cell lines are included. This would be counter to the goal of removing “red tape for low-risk research”, as is stated in the draft.

3. Continued utility of Risk Groups: Risk Groups remain a good baseline, but the draft's expansive definition of 'genetic modification' introduces practical challenges. By including routine laboratory processes like passaging and chemical mutagenesis, the policy risks pulling standard, low-risk RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. The NIH should distinguish deliberate genetic engineering from these routine selection methods. Grounding risk assessments in the actual resulting phenotype and practical BSL guidelines will avoid administrative fatigue and maintain investigator engagement.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): To encourage non-NIH funded institutions to voluntarily comply with the new policies, it is important to keep administrative requirements risk-proportionate and clear. When compliance is seen as an exercise for low-risk work, it can dilute the institutional cooperation needed for overseeing higher-risk research.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: While I fully support transparency and institutional learning, publicly posting complete report templates that include PI names and specific funding details may have an unintended chilling effect on laboratory safety culture. In smaller academic departments or niche fields, these specific details make it simple to identify individual researchers, raising serious privacy and personal security concerns. This level of exposure risks undermining years of institutional effort to build a strong reporting culture for near-misses and minor incidents. The NIH could better achieve its transparency goals by sharing anonymized, aggregated incident data rather than identifiable institutional records.

6. Other feedback relevant to this resource: The research community wants to be a partner in making this new oversight policy successful, but the proposed six-month implementation timeline is simply unrealistic. Redesigning electronic portals, inventorying newly covered research, establishing Biosafety Assurances, and training faculty requires significant institutional coordination. Providing a 12 to 24-month window after the final materials are published would ensure a successful transition.

Date:	October 19, 2026
To:	Office of Science Policy National Institutes of Health 6705 Rockledge Drive, Suite 750, Bethesda, MD 20892
Submission Portal:	Submitted via NIH OSP Electronic Comment Portal
Subject / Notice:	Formal Public Comments and Recommendations on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice Number: NOT-OD-26-112)

ABSA International, the Association for Biosafety and Biosecurity, is a nonprofit professional association representing biosafety and biosecurity professionals in the United States and internationally. Our membership spans academic and research institutions, government laboratories, biotechnology companies, healthcare organizations, public health agencies, and consulting practices. Members bring scientific, technical, operational, and regulatory expertise across diverse biological research and laboratory settings.

ABSA's comments reflect the practical experience of professionals responsible for translating biosafety policy into daily practice. Our members conduct risk assessments, support Institutional Biosafety Committees (IBCs), develop training and containment practices, investigate incidents, and advise institutions on compliance. They understand how policy requirements affect laboratory safety, reporting culture, institutional resources, and the conduct of research.

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public

confidence in NIH-supported science. ABSA supports NIH's efforts to strengthen biosafety oversight. We offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

***Topic to Address**: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:

    a. the nature and stability of the genomic modification;

    b. whether the modification is heritable and the potential for transmission through breeding;

    c. effects on animal health, phenotype, host range, susceptibility, or disease;

    d. potential entry into breeding or food-production systems;

    e. potential environmental release or interaction with non-research animal populations;

    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and

    g. applicable federal, state, or other regulatory oversight.

2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

  Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

ABSA International believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, ABSA International requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, ABSA International welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. ABSA International does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. ABSA International recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, ABSA International recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with ABSA's earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. ABSA International recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, ABSA International kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. ABSA International encourages NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While ABSA supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: ABSA recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Reference basis: Draft NIH Biosafety Policy, Section V-E; NOT-OD-26-112 implementation-resource statement. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7, and Appendix G-II-C-5.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: This policy, while potentially well-intentioned, has a major flaw in that it defines genetic modification to include "ntroduction into cells, organisms, or viruses of nucleic acid molecules that... Can be transcribed or translated". This would include mRNAs, which are the basis for dramatic advances in personalized medicine, cancer treatment, and, of course, vaccines that can be rapidly produced to prevent severe illness and reduce transmission of novel infectious pathogens. mRNAs do not change any cells genetic code (contained in their genomic DNA), they have limited lifetimes, and are not passed down to offspring. mRNA technology has the potential to revolutionize medicine, and by including in under the umbrella of "genetic modification" is not only not accurate but would severely restrict our nation's ability to lead in this area of translational research and disease treatment. Limiting researchers and clinicians ability to work on mRNAs as therapeutic tools would prevent the rapid development of new therapies for previously untreated conditions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

I am responding: On behalf of myself

Name: Sandy Jensen

Name of Organization:

Type of Organization: Not Applicable

Role: Other

Role - Other: Director, IBC Office

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: • The scope is defined as "all biomedical research, in lab settings, involving biohazards" and the provided definition of "Laboratory Research" encompasses clinical settings, which makes the terminology confusing. Would NIH consider clarifying whether the scope includes clinical settings?
• The new policy applies to research supported in whole or in part by NIH and to non-NIH funded research at an institution that receives any NIH funding; does this include institutions that do not receive NIH funding for research involving biohazards but receive it for other research?
• Does record retention have to be based on funding or would the NIH allow it to stand alone on the basis of IBC records?
• Why is a BSO not required for BSL2 work? Most institutions conduct BSL2 work.
• What is meant by "periodically review approved research to ensure compliance" in Section II under IBC Roles and Responsibilities? Is this intended to refer to the de novo review of a protocol every 3 years or to a "Post Approval Monitoring" type program, similar to IACUC? How does it relate to (or is it the same as) the BSO's responsibility to conduct periodic inspections?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): • I support the tiered approach to review. However, can the terminology of "Delegated Review" be changed to "Designated Review" which is familiar to the research community in the IACUC and IRB realms?
• Could NIH consider more clearly stating the authority of the IBC? There are multiple references to approval, but does the IBC also have the authority to disapprove? Request modifications in order to secure approval? Does the delegated reviewer have the same authority, or are there restrictions (e.g. cannot disapprove but must instead call for full committee review)? Codifying the IBC authority in this way would be very helpful.
• "Section IV-3. Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members" as written would treat clinical and basic research identically and prohibit the use of delegated review for clinical studies of widely used therapeutics that involve infusion of genetically-modified, long lived cell types, including the class of CAR-T therapies that have

been used to treat tens of thousands of patients. Clinical studies are conducted on products that have undergone significant biosafety evaluation already and delegated review can improve the throughput and flexibility of clinical studies, thereby lowering their aggregate costs and improving the rate of new, life-saving therapies. It is thus recommended to allow delegated review of clinical studies or at least to provide a carve out for studies that involve investigational products that are substantially similar to currently approved products.

3. Continued utility of Risk Groups: • I find the RG information in the current NIH Guidelines useful when assessing biological agent risk. This works well in tandem with biosafety level information in the BMBL.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: • Institutions should not be forced to use a specific template for the Meeting Minutes. Many institutions use electronic systems, and requiring a specific template will require substantial programming changes (which further makes a 6-month implementation time unrealistic). Instead, would NIH consider stating the elements that must be included and allow institutions to develop their own format.
• Insisting on approval no later than the next convened meeting is unrealistic. Many IBC's allow their members to request changes to the Minutes prior to voting at the next meeting, which would then mean the minutes would come back for a vote to approve during the following meeting.
• Requiring the name of the PI and Grant number is appropriate unless publicly posted; then I believe that information should be redacted. In general, I believe public posting of all incident reports is unnecessary. Instead, would NIH consider allowing institutions to describe their incident reporting procedure in the Assurance, submit the appropriate ones to NIH, and maintain internal records of all others?
• Requiring immediate reporting of incidents within 24 hours in most cases is unnecessary. Would NIH consider allowing institutions to deal with situations and then file a report that includes resolution.

6. Other feedback relevant to this resource: • Six (6) months to implement is not enough time. Not only are there hundreds of protocols to convert, but we need time to obtain an approved Assurance. I recommend at least 18 months, although 3 years would be more realistic, based on the approval period and scope of changes.
• There are references to a "Biosafety Assurance" and its general content. I would like to see a template for that and have an opportunity to comment. Will it be structured similar to an Animal Welfare Assurance and will the review of it be similar? What is meant by "Other pertinent information requested by NIH"?
• While I am not concerned with providing the information in an Assurance, I have concerns with publicly posting some of the requested information on a website. (IACUC doesn't have to do that.) Our procedures are on intranet for benefit of our investigators. Incident reports that do not have to be submitted to NIH should not need to be included, and posting incident reports in general will create a punitive atmosphere that may interfere will full reporting by PIs. Instead, including a description of our incident reporting procedure in the Assurance would provide assurance to the NIH that we have the procedure in place.
• Please clarify the terminology for "externally administered IBC" and whether each site has to have its

“own” IBC of record and “own” Biosafety Assurance. Would NIH consider instead allowing a single local IBC to service multiple local locations under a single Assurance, provided the “covered components” are stated clearly in the Assurance? Again, this approach would be similar to how Animal Welfare Assurances are handled and does not include commercial IBC’s. However, this approach would greatly reduce administrative burden for local IBC’s.

• Please provide a definition of “non-affiliated” member on the IBC. I recommend stating the same definition as is used for IACUC.

• Please define what is meant by “minor” Amendment or clarify that institutions may create their own definition by policy which would then be stated in their Biosafety Assurance.

290. N/A

I am responding: On behalf of an organization

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Scope.
a. Suggest NIH limit its oversight to research covered by the Policy that is supported by NIH funds.
b. Shift from a blanket, process-heavy oversight to a targeted risk-based outcome-focused oversight. Suggest the Policy require less scrutiny and paperwork for low –risk work and more scrutiny for clearly defined high-risk categories.

2. Definition of “laboratory settings.”
a. If limited to laboratory settings - does this exclude animal work that does not occur in a lab setting, and what is lab in this case (are animal rooms considered labs)? Suggest providing a definition of “laboratory setting.”

3. Definition of “biohazard.”
a. It appears that the focus of the Policy is human health. However, it is unclear throughout the Policy if it also covers any plant work (or if it is all excluded, regardless if it’s genetically modified or contains gene drive), animal pathogens (or only if they are zoonotic), cell culture work, etc.. NIH should be explicit about what the Policy covers and be consistent throughout the policy.
b. Established cell lines are mentioned under delegated review, but are not mentioned under the scope unless it would fall under one of the 4 categories in the definition of biohazard. It is unclear if a normal cell line with no additional work with items 1-4 is covered.

4. Definition of Genetic modification.
a. What is included in the chemical or radiological means of altering a genome?

5. GDMO.
a. Define and use consistently throughout the Policy.

6. “Gene drive modified biological agents, GDMOs”
a. Define the difference between these two terms and use them consistently throughout the Policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 1. Implementation period of 6 months.
a. Six months does not give institutions enough time to update software systems, create new policies, and update processes to comply with the new Policy. Suggest at least a year implementation period.

2. Cost of compliance.
a. Compliance with new policies and regulations comes with a cost to institutions – either in staffing, infrastructure, or both. Suggest that NIH consider allowing biosafety costs to be included in direct or indirect cost structures (much like allowable costs for sIRB oversight or data sharing requirements), developing resources and support for the community to assist in compliance, such as training materials, workforce development, or offering funding opportunities for biosafety-related activities.

3. Biosafety Assurance.
a. What are the expectations of what is included in the Assurance (e.g., "other pertinent information requested by NIH")?
b. Is there a template with explicit and clear instructions, such as the PHS Assurance through OLAW for animal research?
c. Who is the Assurance submitted to?
d. Who is to submit it on behalf of the institution? AOR? IBC office staff? Suggest the IBC office staff have the authority to officially submit information to NIH regarding the Assurance rather than the AOR. AOR is typically in the Grant Administration office, and not familiar with biosafety work or interfacing with the IBC office staff.
e. Is all previously approved research to stop while the Assurance is under review and before it is approved? It is unrealistic for an institution to pause all ongoing research now covered by the Policy while Assurances are reviewed. Suggest allowing ongoing research to continue.
f. Is the IBC able to do any official business or reviews while the Assurance is under review?
g. What is the expected timeline for approval from NIH? Currently it takes 6-8 weeks to update committee members on our roster with NIH.
h. Are institutions allowed to rely on other institutions with an Assurance for approval of collaborative work (e.g. subawards) or are institutions required to oversee/approve work at other institutions?

4. Petitioning NIH for determinations.
a. There are many details outlined in what information must be included about the study in petitions for determining containment or lowering containment for RG3 and RG4 agents, including who can submit the petition. However, there are none of those detailed expectations or who can submit provided for cases when an institution petitions for determining biocontainment level for novel agents. Please clarify expectations.

5. IBC Function.
a. An IBC member who has a conflict with a study should not be able to count toward quorum for any decisions made about the study. Suggest NIH clarify quorum requirements and COI expectations for committee members.
b. IBC membership requirements, specifically unaffiliated member requirements, can be especially difficult to meet in communities where the institution is the largest employer. Suggest allowing

institutions to be flexible in their IBC unaffiliated membership requirements, such that it is easier to find an unaffiliated member, yet supports external input and review (e.g., allowing retired employees to serve on the committee).
c. The use of “de novo review.” This terminology can cause confusion. Suggest NIH clarify with a clear definition or use different terminology.

6. Research that requires IBC review and approval.
a. Clarify if minor modifications to full IBC level review studies that do not alter the biological risk assessment can be reviewed by delegated review.

7. “Periodically reviewing approved research.”
a. Clarify what this means for an institution. Is this an annual continuing review? Lab inspections? Post-approval monitoring?
b. How often will approved research be required to be reviewed?
c. Define “other staff” who are able to review ongoing research. Does this mean it is not a formal IBC or IBC delegate review?
d. Suggest defining yearly review (or a specific review interval) and clearly indicate if this review is an official IBC review.
e. The CURES Act was trying to reduce administrative burden and removed the yearly review requirement on the IACUC side - but now we are adding potentially a yearly requirement for IBC? Suggest removing the annual review, if that is what is meant by “periodic review.”

8. Emergency response plans approved by the IBC.
a. Clarify expectation – is this per lab, per study, or institution-wide? Suggest clarifying the acceptance of an institution-wide emergency response plan that has been reviewed/approved by the IBC.

9. Delegated review.
a. Suggest removing the requirement of notifying the IBC when approval is granted and only require notification at the next meeting. Allow for reporting to be a log of reviewed studies as opposed to a report “in full.”
b. Clarify required actions after delegated review such as approval period, continuing review, modifications, etc.
c. Allow institutions to create their own meeting template for delegated reviews and suggest removing the requirement of posting meeting minutes from delegated reviews. Having the same requirements for delegated review as full IBC review, such as meeting minutes and posting for delegated reviews, does not reduce administrative burden on the IBC Administrators or institutions.
d. Suggest NIH follow IACUC regulations and do not require meeting minutes for delegated reviews.

10. “Risk assessment for each specific experiment”
a. Suggest clarifying if this means each project/protocol or each experiment within a protocol?

11. Meeting minutes.
a. Requiring approval of the previous meeting minutes at the subsequent meeting is unrealistic. Suggest staying silent on approval timeline.

b. Why do meeting minutes (and incident reports) need to be posted for five years? Projects are re-written according to this policy every three years so studies from that long ago would no longer even be approved. Please consider shortening this period from five to three years.

12. Training requirement.
a. Training is required of the PI and research team "on the Policy." Will standardized training modules be provided by NIH for institutions to use?
b. What needs to be included in the training?
c. How often is training required?
d. Training is mentioned in the "Responsibilities of the Institution" and "Responsibilities of the PI"; however, the training requirements differ. Please clarify.

13. Responsibilities of the institution.
a. The administrative burden of posting the required information to publicly facing websites is extensive. Suggest not requiring posting details of BSL-2 work or the trainings provided to IBC staff.

14. Responsibilities of the Institutional Biosafety Committee
a. Petitioning NIH to determine the appropriate biocontainment level for research outlined in the draft Policy, including lowering containment involving RG3 and RG4 agents, should be updated as a role of the IBC, instead of specifically the IBC Chair or BSO.

15. Responsibilities of the Biological Safety Officer (BSO).
a. Define the BSO as a required institutional role.
b. Define the BSO as the institution's designated biosafety professional responsible for leading and managing the biosafety program and providing technical biosafety oversight.
c. Clearly outline the authority of the BSO to address significant biosafety concerns that may include: suspend unsafe research activities, require corrective actions, escalate biosafety concerns to institutional leadership, access laboratories and records relevant to research under the purview of the draft Policy. Alternatively, empower the institution to delegate this responsibility to the BSO.
d. Specify core duties tied to the expanded scope of the draft Policy (modernized from IV-B-3 of the Guidelines). These may include: risk assessment and containment guidance, laboratory inspections, incident reporting and response, training and competency verification, and biological safety program oversight.
e. Standardize expectations for inspections, incident reporting, and IBC support.
f. Clarify qualifications and authority of the BSO.

16. Record retention.
a. Request clarification on how long institutions need to keep materials as that section seems confusing. For example, on the IACUC side, the requirement is three years after the close of the study.

3. Continued utility of Risk Groups: 1. NIH Responsibilities – publishing approved determinations of appropriate lower containment…for RG3 or RG4 biological agents."
a. Suggest NIH also publish appropriate containment levels for emerging, novel or zoonotic agents that are not in the BMBL so that other institutions may use the determination.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comments.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1. Meeting minute template.
a. Suggest moving "Readout of Any Projects Approved by Delegated Review" to the bottom of the template. It is currently in the middle of the review elements for a specific project.
b. The amount of information required in template is extensive. For example, the details of the study, the risk assessment, the containment level, etc., are all captured in the protocol, which IBC members have access to. Recreating this information as part of the meeting minutes is a duplication of work/an extra step when information is already included in a protocol. Additionally, the minutes are after the fact - so the project has already been approved. The minutes should focus instead on controverted issues and resolutions rather than recreating protocol information.
c. The extensive nature of the information required in the template raises concerns about the security of the US research enterprise. Providing such detailed information on public facing websites allows the information to be scooped by artificial intelligence and raises security concerns, both to the publicly named PI, the institution, and the whole of the US research enterprise.
d. The template does not appear to be ADA compliant.
e. Suggest NIH provide a list of elements the minutes must contain and allow institutions to use their own templates.

2. Reporting incidents.
a. A 24-hour reporting window is not realistic for large institutions.
b. Thirty days is not long enough to complete a full report.
c. At 30 days, is the final report required, or a full report? Please distinguish between the two as both terms are used.
d. Suggest revising the timeline requirements. Suggest an initial report and then subsequent final report from the institution when the investigation is complete, the IBC is able to review the incident and make determinations of corrective actions, much like the expectation OLAW has for reporting.
e. Noncompliance in most cases does not include "incidents that impose a significant risk to human health" and thus should not be included in the mandatory reporting requirement.
f. Define "low risk incidents" that do not require reporting to NIH.
g. Suggestion – allow incidents that do not require reporting to be handled by the institution and do not require public posting. Additionally, requiring public posting of low-risk incidents may discourage researchers from reporting incidents to the institution.
h. What are we gaining from posting incidents publicly on each institution's websites? Suggest NIH post deidentified incidents reported to them and their response on a centrally located NIH-hosted website.

6. Other feedback relevant to this resource: 1. "Thus, NIH intends to provide additional supplemental materials for the community through implementation resources. These materials will include information about IBC functions, as well as content drawn from existing information, such as biosafety considerations for research with gene drive modified organisms, Risk Group (RG) classifications (currently articulated in Appendix B of the NIH Guidelines); and additional information about requirements for containment practices, occupational health plans, and training for research with RG3 influenza viruses (currently articulated in Section III-D-7 and Appendix G-II-C-5 of the NIH Guidelines)."

a. Will there be expectations beyond the Policy included in these documents? If so, will the community be able to provide comments or feedback? Suggest allowing the community to review and comment on supplemental materials and templates.
b. When are the supplemental materials expected?

2. Risk assessments required as part of IBC review.
a. Suggest NIH provide a template institutions may use to capture information for this review.

3. Risk mitigation plans.
a. Suggest NIH provide a template institutions may use to capture information for review.

Uploaded File: Comment-on-the-Draft-NIH-Biosafety-Policy-for-Research-Invovlving-Biohazards_BSP.docx

Description: Letter of support for CSHEMA Recommendations

16 October 2026

SUBJECT: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Support for CSHEMA Recommendations

To Whom It May Concern:
I am writing to express support for the National Institutes of Health's (NIH) efforts to modernize biosafety oversight and establish a comprehensive, risk-based framework. I appreciate the opportunity to offer feedback on the draft policy.

As a biosafety program associate my work would be directly impacted by the proposed NIH biosafety policy. I endorse the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA). CSHEMA'S recommendations appropriately reflects the practical needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

While I support CSHEMA's comments in full, I would like to draw particular attention to several priority areas that are vital to our institution's operations:

- **Clarification of Key Definitions:** Clearly define foundational terms (e.g. biological agent, toxin, genetic modification, laboratory research, genetically modified organism (GDMO) within the policy to ensure consistent interpretation and compliance across institutions.

- **Recalibration of Public Posting:** Adjust public disclosure requirements to balance public transparency with institutional security and administrative feasibility. Public posting of incidents as drafted is likely to discourage prompt reporting. If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. Remove wording that IBC rosters must be publicly-posted.

- **Implementation Resources & National Risk Database:** Develop comprehensive guidance tools, including a national database for Risk Group and containment determinations, to foster consistent, evidence-based risk assessments.

- **24-Month Phased Transition Period:** Provide a minimum 24-month phased transition period to enable institutions to update procedures, retrain staff, and adapt administrative systems smoothly. Where appropriate, permit conversion at a significant amendment or schedule d renewal, with safeguards and priority for higher-risk work. Preserving staggered renewal cycles will help to avoid unnecessary backlogs.

Thank you for your consideration of these comments and for your commitment to advancing biosafety oversight.

293. Bridget Barker

I am responding: On behalf of myself

Name: Bridget Barker

Name of Organization: Northern Arizona University

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Medical mycology; fungal pathogenesis; biosafety; Risk Group 3 fungal pathogens

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's effort to modernize biosafety oversight and agree that a contemporary framework should address biological hazards beyond recombinant and synthetic nucleic acid research. As an investigator working with Coccidioides, a Risk Group 3 fungal pathogen, I particularly support a framework that considers both wild-type pathogens and genetically modified derivatives. The policy covers wild-type biological agents that cause human disease as well as genetically modified cells and organisms, and it extends beyond NIH-funded projects to covered biomedical research conducted at institutions receiving NIH funding. This represents a substantial expansion from the current NIH Guidelines. I encourage NIH to ensure that this broadened scope is accompanied by correspondingly differentiated levels of oversight and funding support to avoid slowdown in research. Research involving a wild-type RG3 pathogen, an attenuated derivative, a targeted loss-of-function mutant, and a modification reasonably expected to increase pathogenicity may all fall within the policy, but they do not necessarily present equivalent risks. The final policy should emphasize that inclusion within its scope does not imply uniform oversight. Oversight should remain proportionate to the specific biological agent, experimental manipulation, genetic modification, route of exposure, and consequences of an accidental exposure or release.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I strongly support tiered oversight calibrated to actual risk. In particular, I support the distinction in the draft policy between research with RG3 and RG4 organisms requiring IBC review and circumstances requiring additional NIH review. For well-characterized pathogens being studied under established containment conditions, qualified institutional IBCs and biosafety professionals are best positioned to assess the specific facilities, procedures, personnel, and experimental manipulations involved. Additional federal review is most valuable where unusual uncertainty or additional risk exists. The distinction is important for genetic studies of RG3 organisms. Routine genetic modification of an RG3 organism at its established containment level should not automatically trigger federal review solely because a genetic modification has occurred. The nature and anticipated consequence of that modification are critical. A targeted gene deletion intended to determine gene function, reconstitution of that mutation, and a modification reasonably anticipated to increase pathogenicity present different risks. I support retaining local IBC

authority for genetically modified RG3 organisms when research remains at appropriate containment and does not otherwise meet criteria for additional federal oversight. The draft policy's approach of requiring NIH involvement for requests to lower containment for RG3/RG4 organisms provides a reasonable example of circumstances where federal review adds value. Clear boundaries between federal and institutional review will be critical. Ambiguity could result in different institutions sending similar experiments through different regulatory pathways, delaying research without necessarily improving biosafety.

3. Continued utility of Risk Groups: Risk Groups are useful as a baseline for risk assessment, but they should be treated as a starting point rather than as a substitute for experiment-specific risk assessment or as an automatic determination of containment. This distinction is particularly important for genetically modified pathogens. The risk associated with the parental organism provides an appropriate baseline, as recognized in the draft policy, but genetic modification may decrease risk, leave relevant risk essentially unchanged, or increase risk depending upon the biological function affected. My research involves genetic manipulation of the RG3 fungal pathogen Coccidioides. In this context, genetically modified organisms may include targeted loss-of-function mutants generated to investigate metabolism or virulence, complemented strains, mutants with altered developmental phenotypes, and other engineered strains. Classifying all such organisms solely according to the Risk Group of the parental organism does not capture the biological consequences of the modification. Conversely, reducing containment simply because a genetic alteration is predicted to attenuate an organism may also be inappropriate without adequate supporting evidence. I therefore favor an approach in which parental RG establishes the initial baseline, followed by an experiment-specific risk assessment incorporating the nature of the modification, known or anticipated phenotype, experimental manipulation, route of exposure, environmental stability, available phenotypic data, and proposed containment. RG and BSL should not be viewed as competing classification systems. Risk Group describes characteristics of the biological hazard, whereas appropriate containment must also account for how that hazard will actually be manipulated. The strongest framework would retain RG as a useful starting point while relying upon BMBL-aligned, experiment-specific risk assessment to determine appropriate containment and mitigation.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NA

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I support timely reporting and careful analysis of laboratory-acquired infections, meaningful exposures, releases, and significant containment failures. These reports provide an important opportunity to identify recurring risks and improve biosafety practice. For BSL-3 and ABSL-3 laboratories, however, reporting criteria must distinguish events that represent a potential exposure, loss of containment, or credible risk to personnel or the community from minor deviations or equipment events that remain fully contained by redundant engineering and procedural controls. The draft policy identifies multiple categories of reportable incidents at BSL-3/ABSL-3 and requires rapid notification for covered incidents. NIH should provide concrete examples distinguishing reportable incidents from events appropriately documented and addressed locally. Consistent definitions will be important both for meaningful national biosafety data and for consistency among institutions. I also support transparency in IBC oversight, but public posting of IBC minutes and incident reports presents particular concerns for high-containment pathogen research. The policy should establish clear, nationally consistent standards governing redaction of security-

sensitive facility information, personnel information, proprietary or unpublished scientific information, and information whose disclosure could itself create biosafety or biosecurity concerns. IBC minutes should communicate the basis and outcome of biosafety oversight without requiring the public disclosure of experimental or facility details unnecessary to demonstrate appropriate oversight and represents a safety risk to workers. As stated, any entity can access these records, including foreign competitors and bad actors.

6. Other feedback relevant to this resource: Implementation guidance will be critical to successful application of this policy. I particularly encourage NIH to develop scenarios involving a broad range of biological systems rather than relying predominantly on examples involving viruses or bacteria. RG3 fungal pathogens present distinct biosafety considerations involving developmental state, sporulation, environmental stability, route of exposure, animal infection models, and the phenotypic consequences of genetic modification. Coccidioides provides a particularly relevant example because modern studies increasingly combine genomics, targeted genetic manipulation, phenotypic characterization, and animal infection experiments. This pathogen is naturally growing in the environment with high genetic diversity, naturally infects thousands of US citizens every year, and is acquired through environmental exposure, not transmitted person to person. This is very different than viral or bacterial infectious agents. NIH should include fungal pathogens explicitly in its examples and engage investigators and biosafety professionals experienced with medical mycology and RG3 fungi in developing implementation materials. Fungi are distinct and non-transmissible. A policy that combines clear national standards with organism-specific scientific expertise and meaningful local risk assessment will provide stronger biosafety oversight than one relying primarily upon categorical classifications.

294. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Other

Role: Member of the Public

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Define "incident" better. Add RG definitions (especially if the RG list is being removed temporarily). Define clinical research. Take a "one health" approach, still seems focused on human and would be helpful to include human, animal and plant. Clarify whether oligonucleotides, cells, and toxins are intended to fall within the definition of biological agent. Broaden or clarify the definition of toxin, which appears limited to peptides and proteins and does not clearly address synthetic toxins (are they out of scope?) Clarify whether mycotoxins fall within the policy's definition of "toxin" and are considered biohazards under the policy. Include animal biosafety containment level (ABSL) laboratories within the definition of laboratory research. Define "organism" and clarify its boundaries relative to cells, viruses, biological agents, synthetic or minimal-cell systems, multicellular models, animals, and other engineered biological systems; include examples and exclusions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Bring back RG examples and expand to include animal and plant pathogens (rather than keeping the focus primarily on human pathogens). Risk group is a great "input" to the hazard characterization/identification part of your risk assessment. Although risk group is not all that is needed in hazard identification, it is a helpful component along with scale, physical form, environmental stability, routes of transmission, susceptible species, endemicity, and many other factors. Biosafety level is more of an output of the risk assessment, telling you how what containment level/ controls are needed to work safety with the biological material.

Clarify how synthetic nucleic acid molecules should be evaluated within the Risk Group framework, including whether they should be assigned a Risk Group or evaluated using separate risk-based criteria.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Do not require information in the report that may be deemed sensitive, such as the name of Principle Investigator as

documenting personal information may violate privacy regulations and result in under reporting.

Define 24-hour reporting (meaning 24 hours from what time? When the PI or BSO are alerted of an issue?) Consider defining as 24-hours from “confirmed “reportable event rather than just 24 hours report.

Define what a release is (may mean different things at different biosafety levels, and also within the context of biosecurity).

6. Other feedback relevant to this resource: Keep appendix K for large scale containment guidance. Currently BMBL, Appendix M states, "Appendix K of NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines) prescribes safety practices and containment procedures for large-scale (i.e., >10 liters per container) facilities. These guidelines can be applied to all large-scale work with biological materials (e.g., genetically modified organisms [GMO] and non-GMO, human, and animal/zoonotic pathogens). Please ensure familiarity with local regulations as these may differ from recommendations in this text." Until BMBL is updated to incorporate current appendix K information, where do we go to find large scale requirements? Is there an interim solution that can be written into NIH Guidelines until BMBL can be updated?

Why only require a BSO be on an IBC when the institution conducts research at BSL-3, BSL-4 or research involving GDMOs? Most LAIs result in BSL-2 labs, so would it not be beneficial to have a BSO evaluate BSL-2 work as well? They bring a unique risk-based perspective that a PI may not have.

At least two members who are not affiliated with the institution, other than their membership on the IBC, to represent the interest of the surrounding community with respect to health and protection of the environment - specify the qualifications or selection criteria for this role.

The policy should clarify whether IBC community members must reside within a specified distance of the site served by the IBC.

Provide for how institutions may petition NIH to assign a Risk Group to a new or emerging agent not addressed in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

Provide a single, clearly identified reporting pathway to report incidents.

Clarify whether theft of biohazardous material is a reportable incident and whether biosecurity incidents are within the scope of the policy.

Please provide stakeholders an opportunity to review and comment on the next draft of the policy.

295. N/A

I am responding: On behalf of myself

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Children's health

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definition of "genetic modification" as reported here is incorrect:
Genetic modification:
The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
-Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing);
or Have the potential for one or more cycles of replication in a cell;
or Can be transcribed or translated;

By definition any transient expression of a nucleic acid that "can be transcribed or translated" is not a genetic modification. Please fix this whohc might have much broader impact on many practices.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

296. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Government Agency

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Clinical research, Basic research, I am a biosafety professional

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: More containment guidance is needed from appendix B.
Terms have no definition or are poorly defined.
Biosafety language in clinical research should adhere more towards infection prevention terminology.
A One Health approach should include plant and animal research.
"Desgnated Member Review" should be explicitly defined as it is for IACUC's

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Requirements for a biosafety officer at an institution needs to be expanded beyond BSL3/4 and gene drive research. The proposed changes makes the need of a biosafety officer at an institution imperative for compliance and the role of the BSO needs to elevated in importance in the institutional safety hierarchy.

3. Continued utility of Risk Groups: The NIH requires approval of risk groups and containment, but provides no guidance in appendix B.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Posting full incident reports WILL result in hippa violations of research staff. PI and grant information should not be made public. Posting thr basic facts of a biosafety incident will accomplish the stated aim of reporting transparency.
Full and complete incident reports involving select agents will alert bad actors as to the location of these agents and constitute a security risk.
24hr reporting is poorly defined. 24hrs from what?

6. Other feedback relevant to this resource: The administrative burden proposed in these changes is an unfunded mandate.
NIH should provide direct guidance defininig risk groups and the required containements.

Insitutional requirements in designating a biosafety professional should be broadened beyond extreme containment use cases.

I am responding: On behalf of myself

Name: Jennifer Ramil

Name of Organization: Sanford Burnham Prebys

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Institutional Biosafety Committee, Safety, Research Compliance

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's efforts to expand biosafety oversight beyond recombinant and synthetic nucleic acid research to address biological hazards that may not be adequately covered under the current NIH Guidelines. However, I am concerned that the proposed scope is overly broad and is not consistently aligned with the subsequent categories of research requiring full IBC review.

In particular, the proposed definition of genetic modification includes stable genomic alterations resulting from passaging, reassortment, chemical treatment, or radiological means. These techniques are used in a wide variety of routine biomedical research activities, many of which do not meaningfully increase biological risk. When considered alongside the proposed review categories, this broad definition could substantially increase the amount of research requiring full IBC review rather than delegated review. This appears inconsistent with NIH's stated objective of reducing administrative burden for lower-risk research.

I am also concerned that the proposed requirement for IBC review of primary cells that may contain adventitious pathogens could effectively encompass most primary human and animal cell research, since the possibility of adventitious contamination cannot always be excluded. While certain primary-cell materials warrant additional oversight, routine primary-cell research should not automatically require full committee review based solely on the theoretical possibility of contamination.

I recommend that NIH clarify the scope of covered research and establish clearer, risk-based criteria that distinguish routine biological research from activities presenting meaningful biological hazards. The policy should also explicitly clarify the relationship between full committee and delegated review categories to ensure that research eligible for delegated review is not inadvertently captured by broader classifications.

Ultimately, the level of IBC oversight should be determined by the actual biological risks associated with the research, rather than the techniques used or the theoretical presence of a hazard. This approach

would allow institutions to focus their limited biosafety resources on research presenting meaningful risks while maintaining appropriate oversight of lower-risk activities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support the proposed tiered oversight framework and the concept of allowing lower-risk research to undergo delegated review while reserving full IBC and federal oversight for activities presenting greater biological hazards. However, I am concerned that the proposed review categories are not consistently calibrated to actual risk and may unintentionally increase full committee review of routine biological research.

In particular, the broad definition of genetic modification, which includes alterations resulting from passaging, reassortment, chemical treatment, or radiological means, could result in a substantial amount of lower-risk research requiring full IBC review. The proposed categories also appear to overlap, with certain genetically modified cells, viruses, and organisms potentially qualifying for both full committee and delegated review. NIH should clarify which review category takes precedence when research meets the criteria for more than one tier.

I am also concerned that requiring full committee review of primary cells that may contain adventitious pathogens could encompass most primary-cell research, regardless of whether the materials present an elevated biological risk.

From my experience as an IBC Chair, effective biosafety oversight depends on allowing institutions to evaluate the specific hazards associated with proposed research and assign an appropriate level of review. Institutional biosafety professionals and IBCs are well positioned to assess agent characteristics, experimental manipulations, containment practices, personnel training, and available institutional resources.

I recommend that NIH provide greater flexibility for delegated review and establish clearer criteria distinguishing research that requires full committee approval from research that can be appropriately reviewed at the institutional level through a delegated process. Full committee review should focus on research involving significant or increased biological hazards, while lower-risk activities should be eligible for delegated review even when they involve genetic modification or potentially infectious biological materials.

I also support retaining federal oversight for research presenting particularly significant or uncertain risks, including activities requiring NIH approval before initiation. However, routine determinations involving established agents, standard laboratory practices, and well-characterized risks should generally remain under local institutional oversight.

Expanding full committee review without a corresponding increase in biological risk will create additional administrative work for investigators, biosafety offices, and IBC members without necessarily improving laboratory safety.

The tiered framework should prioritize the biological risk of the research rather than the classification of the technique or material alone. Clearer distinctions between review categories, greater flexibility for

delegated review, and appropriate institutional discretion would help NIH achieve its goal of strengthening biosafety oversight while reducing unnecessary administrative burden.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I support NIH's efforts to standardize incident reporting and IBC meeting minutes to promote consistency, transparency, and accountability across institutions. However, I have significant concerns regarding the proposed public disclosure requirements, particularly the potential unintended consequences for institutional safety culture and the relationship between researchers and biosafety professionals.

Draft Incident Reporting Template

My greatest concern is the requirement for institutions to publicly post incident reports, including incidents that are reviewed by the IBC but do not meet the threshold for reporting to NIH.

As a biosafety professional and IBC Chair, I believe one of the most important elements of an effective biosafety program is maintaining an open, collaborative relationship with researchers. I work to foster an environment where researchers view the biosafety office as a resource and partner rather than simply a regulatory enforcement function. Researchers need to feel comfortable promptly reporting exposures, spills, procedural errors, equipment failures, near misses, and other potential safety concerns.

I am deeply concerned that requiring public disclosure of incident reports could undermine this relationship.

The proposed incident-reporting template includes the Principal Investigator's name and associated NIH grant information. Although individual laboratory personnel should not be identified, the PI's identity and funding information would generally remain publicly available. I worry that researchers may become reluctant to report incidents if they believe doing so could negatively affect their PI's reputation, research program, or future funding opportunities.

This concern is particularly relevant for graduate students, postdoctoral researchers, and other laboratory personnel who may hesitate to report an incident if they believe it could have consequences for their PI or laboratory.

I am especially concerned about requiring public disclosure of lower-risk incidents that do not warrant NIH reporting. If an institution has appropriately investigated an incident, evaluated the potential hazards, and implemented corrective actions, I question what additional biosafety benefit is achieved by publicly identifying the investigator and research program involved.

I strongly recommend that NIH establish a centralized, de-identified national biosafety incident reporting database rather than requiring institutions to publicly post individually identifiable incident reports.

Institutions could submit standardized incident reports to NIH for appropriate oversight, while NIH could maintain a publicly accessible database containing de-identified information about incident types, biological agents, contributing factors, root causes, containment failures, corrective actions, and lessons learned.

I believe this would be an incredibly valuable resource for biosafety professionals. Currently, lessons learned from laboratory incidents are often limited to the institutions where they occurred. A centralized national database would allow institutions to identify recurring problems, learn from incidents at other research institutions, and implement preventive measures based on shared experiences.

This approach would advance transparency and collective learning without creating unnecessary disincentives for researchers to report incidents.

Ultimately, we should be creating policies that encourage researchers to report more incidents, not policies that may make them think twice before contacting Safety.

Draft IBC Meeting Minutes Template

I support the use of a standardized meeting-minutes template to promote consistency in IBC documentation and ensure that committees appropriately document their risk assessments, discussions, and approval decisions.

However, I am concerned about the level of detail required in publicly accessible meeting minutes, particularly the inclusion of detailed experimental manipulations, biological agents, and protocol-specific risk assessments.

IBC members need comprehensive information to conduct meaningful risk assessments, and institutions should maintain detailed internal records documenting those assessments. However, I do not believe that all of this information needs to be included in publicly posted meeting minutes.

Requiring extensive technical details in public meeting minutes may result in disclosure of scientifically sensitive, proprietary, or preliminary research information. It may also increase administrative workload without necessarily improving public understanding of institutional biosafety oversight.

I recommend that NIH distinguish between the detailed documentation necessary for effective internal IBC review and the information necessary to demonstrate appropriate oversight to the public.

Public meeting minutes should provide sufficient information to demonstrate that the IBC evaluated the relevant hazards, established appropriate containment measures, and made an informed approval decision, without requiring unnecessary disclosure of detailed experimental information.

NIH should also provide clearer guidance regarding appropriate redactions and allow institutions reasonable discretion to protect legitimate research confidentiality and security interests.

Overall, I support standardized reporting and documentation requirements, but I encourage NIH to ensure that transparency requirements do not undermine the effectiveness of institutional biosafety programs. Transparency should promote accountability, shared learning, and improved safety practices without discouraging incident reporting or creating unnecessary administrative burdens.

6. Other feedback relevant to this resource: I appreciate NIH's efforts to provide standardized templates and implementation resources to support the transition to the proposed biosafety policy. However, given the substantial changes to the scope of covered research, IBC review requirements, incident reporting, and public disclosure obligations, I believe additional guidance and a longer implementation period will be necessary.

Implementation Timeline

I am concerned that the proposed six-month implementation period is insufficient given the magnitude of the changes. Institutions will need to revise their biosafety policies, IBC procedures, protocol registration systems, review classifications, incident-reporting processes, and public disclosure practices. Investigators, biosafety professionals, and IBC members will also need training on the new requirements.

I recommend a phased implementation period of at least 24 months, particularly for institutions with established IBC programs that will need to transition existing protocols to the new oversight framework.

Additional Guidance and Resources

I would particularly appreciate NIH providing guidance in the following areas:

1. Scope and applicability: Clear examples of research activities that fall within and outside the policy, particularly routine cell culture, primary-cell research, genetic modifications resulting from passaging or chemical/radiological treatment, and other activities that have not traditionally required IBC review.

2. Full committee versus delegated review: A decision tree or classification matrix that clearly identifies which research activities require full committee review and which are eligible for delegated review. NIH should clarify how to resolve situations where research appears to meet criteria for both categories.

3. Risk assessment and containment: Practical examples demonstrating how Risk Groups, genetic modifications, experimental manipulations, and BMBL recommendations should be considered together when determining appropriate Biosafety Levels and containment practices.

4. Transition of existing IBC protocols: Guidance on whether previously approved research must undergo immediate reclassification or review, how existing approval periods will be handled, and whether institutions may transition protocols at their next scheduled renewal.

5. Incident reporting: Clear reporting thresholds, examples distinguishing NIH-reportable incidents from incidents requiring only institutional review, and guidance on which lower-risk incidents require formal documentation. I also strongly encourage NIH to reconsider institutional public posting requirements and develop a centralized, de-identified national incident reporting database.

6. Public meeting minutes and redaction: Examples of appropriately completed public meeting minutes, including the level of risk-assessment detail expected and clear criteria for protecting sensitive research information.

7. Protocol approval and renewal: Guidance on the three-year approval requirement, including whether unchanged, lower-risk research may undergo streamlined or delegated renewal rather than a full de novo review.

I also recommend that NIH provide standardized training materials, frequently asked questions, and opportunities for institutions to submit implementation questions as the policy takes effect.

Additional Public Comment Opportunity

Given the breadth of the proposed changes and the ambiguities surrounding scope, review classifications, and public disclosure requirements, I encourage NIH to consider releasing a revised draft for an additional public comment period before finalizing the policy.

As a biosafety professional and IBC Chair, I recognize that implementation guidance must be sufficiently detailed to promote consistency across institutions while allowing flexibility for institution-specific risk assessments.

Ultimately, successful implementation should be measured by whether the policy improves biosafety oversight and allows institutions to focus their resources on meaningful biological hazards, rather than simply increasing the number of protocols, committee reviews, and administrative requirements.

298. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/16/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): allergy/immunology, autoinflammatory and immune dysregulation diseases, and clinical/translational research involving human biospecimens, patient-derived cells, molecular diagnostics, therapeutic development, registries, and non-replicating nucleic-acid or viral-vector technologies

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's goal of modernizing biosafety oversight and ensuring that oversight is appropriately aligned with scientific and technological developments. The proposed expansion from recombinant or synthetic nucleic-acid research to research involving biohazards is understandable and potentially valuable. However, the scope should be defined with sufficient precision to avoid treating biologically and operationally distinct activities as equivalent.

In particular, the definition of "genetic modification" should distinguish stable or heritable genetic alterations from transient, non-integrating, non-replicating nucleic-acid delivery and expression. As currently drafted, the definition includes nucleic-acid molecules that "can be transcribed or translated." This language could encompass transient systems such as synthetic mRNA, transient plasmid expression, siRNA-related systems, and other non-integrating platforms, even when they do not persist, replicate, integrate, alter the genome, or create a heritable change.

NIH should clarify that transient expression alone does not constitute genetic modification for purposes of this Policy when the nucleic acid:

does not integrate into or otherwise stably alter the genome;
cannot replicate or support replication;
is not maintained or propagated in the recipient cell or organism; and
does not create a meaningful biosafety hazard beyond the transient biological activity of the expressed product.
Alternatively, NIH could retain the broader definition but establish an explicit low-risk category for transient, non-integrating, non-replicating nucleic-acid systems. Such work could be subject to proportionate institutional notification or delegated review rather than full IBC review.

The scope should also clearly distinguish among:

genome editing or integrating systems;
replication-competent or potentially shedding vectors;
replication-defective, non-integrating viral vectors;
transient mRNA or nucleic-acid delivery;
well-characterized human or animal cell lines;
primary cells and tissues that may contain adventitious agents; and
clinical products administered to human participants.
The policy should avoid inadvertent gaps involving novel synthetic biology systems, engineered cell lines, gene-editing systems, replication-defective vectors, and biologic products with potential for shedding or environmental dissemination. At the same time, it should avoid imposing equivalent oversight on low-risk transient systems and high-risk systems capable of integration, replication, persistence, environmental spread, or clinically significant transmission.

A clear decision tree, with representative examples, would substantially improve consistency across institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered oversight structure is appropriate and preferable to a uniform review requirement. Oversight should be proportional to the characteristics of the biological material, the genetic modification, the experimental manipulation, the route and scale of exposure, the potential for replication or shedding, and the potential consequences of an accidental release.

The proposed division among federal NIH review, institutional IBC review, delegated IBC review, and investigator-level responsibilities is generally reasonable. However, the policy should provide more objective criteria for assigning research to each tier. Institutions and investigators need to be able to determine prospectively whether a project requires:

NIH and IBC approval;
full IBC approval;
delegated or expedited IBC review; or
documentation without prospective IBC approval.
NIH should consider a formal risk matrix that includes:

Risk Group and known pathogenicity of the parent agent;
whether the modification affects host range, tissue tropism, virulence, immune evasion, persistence, replication, or shedding;
whether the construct is integrating or non-integrating;
whether replication is competent, defective, or impossible;
the expression product and its biological activity;
route, dose, scale, and frequency of exposure;
use in humans, animals, or environmental settings;
potential for environmental persistence or dissemination; and

availability of effective prophylaxis, treatment, or containment.
The policy should also provide clear transition and grandfathering provisions for protocols already reviewed under the current NIH Guidelines. Requiring full re-review of every existing protocol could overwhelm IBCs and delay research without necessarily improving safety. Existing approvals should be recognized where the risk assessment remains substantively unchanged, with re-review triggered by material changes or at the next scheduled renewal.

Federal review should be reserved for research presenting substantial uncertainty, unusually high consequences, novel agents, or risks that cannot be adequately evaluated using existing classifications and guidance. Routine, well-characterized, low-risk research should remain at the institutional or delegated-review level.

NIH should establish expected review timelines, mechanisms for requesting clarification, and a process for resolving disagreements between NIH and an institutional IBC. The local IBC should be permitted to require more stringent controls based on local facilities, personnel, procedures, and institutional expertise.

3. Continued utility of Risk Groups: Risk Groups and Biosafety Levels serve different but complementary purposes and should both be retained.

Risk Group classifications provide a useful baseline description of the intrinsic hazards associated with an agent, including pathogenicity, transmissibility, disease severity, and availability of preventive or therapeutic measures. Biosafety Levels describe the containment practices, equipment, facilities, and operational controls needed for a particular activity.

Neither RG nor BSL should be used as a complete substitute for the other. A Risk Group classification should not automatically determine the required BSL for every experiment, and BSL alone does not adequately describe the biological hazard of an agent or genetic modification.

For genetically modified agents, the risk assessment should consider the characteristics of both the parent agent and the introduced genetic material. Relevant factors include whether the modification changes:

host range or tissue tropism;
replication competence;
virulence or pathogenicity;
toxin production;
immune evasion;
persistence or latency;
environmental stability;
shedding or transmission; or
susceptibility to available treatment or prevention.
NIH should provide a clear crosswalk showing how RG classifications, BSL/ABSL containment, genetic modifications, and experimental manipulations should be considered together. The policy should also clarify how institutions should proceed when a modified agent does not fit cleanly within an existing RG

classification or BSL recommendation.

A risk-based approach is particularly important for attenuated, replication-defective, non-integrating, or otherwise biologically restricted systems. These systems may warrant lower containment than the parental agent in some circumstances, but any reduction should be supported by data and reviewed by the IBC. Conversely, a nominally lower-RG agent may require additional controls if a modification increases biological activity, persistence, host range, or environmental risk.

The BMBL should remain an important primary reference for containment and laboratory practices, while NIH should provide additional guidance for genetic modifications and novel systems that are not adequately addressed in the BMBL. The draft policy appropriately recognizes that risk assessment must consider the characteristics of the biohazard, the manipulations, and the genetic modifications.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary compliance through education, practical tools, transparency, and recognition rather than through language that creates uncertainty or disproportionate administrative obligations.

The policy should provide a clearly defined voluntary framework for institutions and investigators conducting research outside the formal scope of the Policy, including research at non-NIH-funded institutions. This framework could include:

a voluntary biosafety assurance or institutional attestation;
model IBC policies and standard operating procedures;
access to NIH training materials;
a publicly available self-assessment checklist;
a risk-assessment template;
examples of appropriate review pathways;
access to consultation with biosafety experts; and
eligibility for voluntary submission of de-identified near-miss and incident data.
Voluntary reporting of near misses and procedural weaknesses is most likely to be successful if institutions are assured that appropriately submitted, non-negligent information will be used for learning and prevention rather than punitive enforcement. The draft policy proposes voluntary, confidential reporting of certain near misses and procedural issues to a national biosafety data center; NIH should provide clear safeguards regarding confidentiality, data de-identification, and limits on enforcement use. (grants.nih.gov)

NIH should also clarify whether voluntary adoption of the Policy by a non-NIH-funded institution creates any additional legal, reporting, or public-disclosure obligations. Institutions should be able to adopt commensurate oversight without unintentionally assuming requirements designed for NIH-funded institutions.

Voluntary compliance would be encouraged by making the framework straightforward, risk-based, and compatible with existing institutional biosafety programs and applicable federal, state, and local requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Standardized templates could improve consistency, transparency, and the quality of biosafety data. However, the templates should be designed to minimize unnecessary duplication and protect privacy, proprietary information, confidential personnel information, and sensitive security-related information.

For the incident reporting template, NIH should clearly distinguish among:

reportable incidents requiring notification to NIH;
incidents requiring institutional or IBC review but not NIH notification;
near misses and procedural deviations; and
minor spills or events that do not require formal reporting.
The template should include structured fields for:

date, location, and research activity;
biological agent or material;
Risk Group and containment level;
type and severity of exposure;
whether an environmental release occurred;
whether an infection, injury, or medical evaluation occurred;
immediate corrective actions;
institutional investigation and root-cause analysis;
corrective and preventive actions;
whether the IBC, BSO, occupational health program, IRB, IACUC, or other oversight body was notified; and
whether the incident is being reported to NIH or retained at the institutional level.
The template should not require personally identifiable health information or unnecessary details about individual employees or research participants. NIH should provide clear instructions regarding when an initial notification is due, what information may be submitted later, and how amended or final reports should be handled. The draft currently contemplates immediate notification for certain significant events, followed by a fuller report within 30 days. (grants.nih.gov)

For the meeting-minutes template, NIH should include fields for:

date and meeting type;
attendance and quorum;
conflicts of interest and recusals;
protocols reviewed;
risk assessment summary;
containment level and rationale;
required conditions or modifications;
vote or determination;
delegated reviews reported to the IBC;
incident reviews;
training or policy updates; and

identification of information redacted before public posting.
NIH should clarify what information must be publicly posted and what information may be redacted to protect privacy, proprietary interests, confidential information, and institutional or national security. The draft proposes public posting of IBC meeting minutes and incident reports, with redactions where appropriate. (grants.nih.gov)

NIH should also consider providing separate public and confidential versions of incident reports and meeting minutes. Public disclosure requirements should not discourage accurate reporting or cause institutions to omit useful safety information.

6. Other feedback relevant to this resource: Successful implementation will require detailed guidance, practical examples, and adequate transition time. NIH should publish implementation materials before the final policy becomes effective and should provide a reasonable transition period for institutions to update policies, train personnel, revise databases, and modify IBC workflows.

The following resources would be particularly valuable:

A scope and applicability decision tree

This should address wild-type agents, genetically modified cells, plasmids, mRNA, siRNA, gene-editing systems, viral vectors, replicons, cell lines, primary cells, human biospecimens, toxins, prions, and clinical products.

Clear examples of genetic modification

NIH should explicitly address transient mRNA, transient plasmid expression, non-integrating vectors, replication-defective vectors, genome editing, episomal systems, synthetic biology constructs, and engineered cell lines.

A risk-assessment worksheet

The worksheet should integrate agent characteristics, genetic modifications, experimental manipulations, host range, replication, persistence, shedding, route of exposure, scale, and available mitigation.

A crosswalk among RG, BSL/ABSL, and oversight categories

This should explain when a project requires NIH review, full IBC review, delegated review, or documentation only.

Clinical research guidance

NIH should clarify oversight for investigational products administered to humans, including products that are non-replicating and non-integrating but may transiently express a protein. Guidance should address shedding, persistence, product administration, interaction with IRB and FDA requirements, and the

endpoint at which IBC oversight may conclude.

Human biospecimen and cell-line guidance

Institutions need practical direction regarding primary human cells, adventitious agents, commercially available cell lines, patient-derived cells, organoids, and specimens obtained under clinical care.

Incident-reporting guidance

NIH should provide examples of reportable and non-reportable events, near misses, occupational exposures, minor spills, animal incidents, equipment failures, and potential laboratory-acquired infections.

Public-posting and redaction guidance

NIH should define how institutions should protect personal privacy, proprietary information, confidential medical information, and security-sensitive details while meeting transparency goals.

Transition and grandfathering guidance

Existing approvals under the current NIH Guidelines should remain valid unless the risk profile has materially changed. NIH should provide a process for updating existing protocols without requiring unnecessary full re-review.

Training and technical assistance

NIH should provide standardized training for investigators, IBC members, biosafety officers, and institutional officials, as well as a mechanism for obtaining timely answers to implementation questions.

NIH has appropriately recognized that additional resources will be needed to implement a modernized policy. The final policy should not become effective until institutions have access to sufficiently detailed guidance, templates, examples, and a workable mechanism for resolving ambiguous cases

SUBJECT: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Support for CSHEMA Recommendations

To Whom It May Concern:
I am writing to express support for the National Institutes of Health's (NIH) efforts to modernize biosafety oversight and establish a comprehensive, risk-based framework. I appreciate the opportunity to offer feedback on the draft policy.

As a member of Biosafety, my work would be directly impacted by the proposed NIH biosafety policy. I endorse the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA). CSHEMA'S recommendations appropriately reflects the practical needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

While I support CSHEMA's comments in full, I would like to draw particular attention to several priority areas that are vital to our institution's operations:

- **Clarification of Key Definitions:** Clearly define foundational terms (e.g. biological agent, toxin, genetic modification, laboratory research, genetically modified organism (GDMO) within the policy to ensure consistent interpretation and compliance across institutions.

- **Recalibration of Public Posting:** Adjust public disclosure requirements to balance public transparency with institutional security and administrative feasibility. Public posting of incidents as drafted is likely to discourage prompt reporting. If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. Remove wording that IBC rosters must be publicly-posted.

- **Implementation Resources & National Risk Database:** Develop comprehensive guidance tools, including a national database for Risk Group and containment determinations, to foster consistent, evidence-based risk assessments.

- **24-Month Phased Transition Period:** Provide a minimum 24-month phased transition period to enable institutions to update procedures, retrain staff, and adapt administrative systems smoothly. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserving staggered renewal cycles will help to avoid unnecessary backlogs.

Thank you for your consideration of these comments and for your commitment to advancing biosafety oversight.

Sincerely,

Member of Biosafety

300. Boston Children's Hospital

I am responding: On behalf of myself

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: First, the definition of genetic modification is inaccurate. Transient expression of nucleic acids that “can be transcribed or translated” is not a genetic modification by definition, because the host's DNA is NOT modified. This new oversight would impact the use of any transient gene expression system, which are not genetic modifications, for instance transient expression of proteins for recombinant antibody expression, or mRNA delivery.
Moreover, harmless Risk Group 1 (RG1) organisms containing basic plasmids, non-pathogenic mammalian cell lines, and standard reporter genes (like GFP) are now captured under federal oversight. Expanding the scope to include safe, non-pathogenic, and well-characterized laboratory models dilutes the term "biohazard." It creates unnecessary regulatory friction for foundational work that carries zero public health risk.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposal would force historically exempt, innocuous research into a pre-initiation review pipeline. Investigators would have to submit formal protocols and wait for an IBC member or subgroup to grant permission before they can start basic work. The proposed tiered oversight introduces a clerical bottleneck for thousands of low-risk laboratories. Shifting safe research from an "exempt" status to a mandated pre-approval process will choke institutional research velocity without providing any safety benefit.

3. Continued utility of Risk Groups: Trapping of RG1 Organisms via "Genetic Modification" Definitions will force historically low-risk or non-pathogenic laboratory models into a formal compliance pipeline and create an artificial regulatory burden without any measurable gain in public biosafety. Labeling standard, innocuous cellular tools as "biohazards" dilutes the meaning of the term and distracts Institutional Biosafety Committees (IBCs) from monitoring true high-consequence pathogens. For thousands of labs using innocuous agents, shifting from an "exempt" status to requiring pre-initiation approval introduces administrative bottlenecks. This slows down basic foundational research and places an immense clerical burden on institutional staff. This policy functions as an unfunded mandate and diverts limited biomedical research dollars away from actual science and into institutional compliance machinery to track harmless materials.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Publicly posting minor, zero-risk incidents (like a standard lab mouse escaping its cage or a minor spill of a benign agent) exposes institutions to unwarranted public scrutiny, media sensationalism, and reputational damage for events that carry absolutely no public health risk.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As the Principal Investigator of a research laboratory who has been leading research teams for 15 years at an R1 level university in the US: The definition of 'genetic modification' should NOT include transient expression or the ability to be transcribed or translated. Transient transfection of nucleic acids is a key technique in my field that is required to visualize the microscopic changes that allow us to distinguish one stage of cancer from another. Transiently transfected material cannot self-propagate, and persists for mere hours or days. Transfected material that is transcribed and translated in cells does not pose significant biosafety risk to humans, as there is no modification to the genome of the target cells, or any other living material that the constructs come into contact with.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): NA

3. Continued utility of Risk Groups: BSL are more robust.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NA

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biochemistry and Molecular Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Although I write in my personal capacity, it is worth noting my professional qualifications. I earned my PhD in Molecular Microbiology and Immunology, I have run an NIH-funded research laboratory for most of the last 22 years, I have taught upper level Biochemistry to about 5,000 undergraduate students, and I wrote molecular genetics curriculum that is currently delivered to medical students in five US states.

I am writing to point out a basic error in the proposed policy. The proposed policy states that:

"Genetic modification" includes "The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
[…] • Can be transcribed or translated…'"

As any of my undergraduate students, graduate students, or medical students would be able to explain, genetic material is by definition *heritable.* However, many types of nucleic acids that can be introduced into cells are *not heritable.* Examples of the latter include but are not limited to: nucleotides, oligonucleotides, and their derivatives; non-replicating and non-integrating nucleic acid chains delivered by replication-deficient viruses and pseudoviruses; and non-replicating and non-integrating DNA and RNA (and derivatives) introduced by transient transfection.

The proposed definition is incorrect. It is theoretically incoherent and in practice, useless. It must be amended.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definition of biohazards is problematic. The current definition appears to consider the introduction of mRNA (a non-heritable molecule) as a genetic modification. This is nonsensical and not appropriate for the regulations.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Many thanks for providing the opportunity to comment on the draft NIH guidelines.
(1) The draft NIH guidelines still seem to be rooted in the thinking of the early days of genetic engineering when pretty little was known about the intrinsic risks of genetic engineering. I would strongly recommend that the NIH carefully considers appropriate wording that reflects the current state of knowledge. Examples include the following:
(a) Page 14: "Research involving GDMOs requires risk assessments that incorporate a broader scope of considerations because of GREATER UNCERTAINTY of the technology and POTENTIAL UNCERTAINTY of the impact of the newly modified organism or biological agent." This is a statement focussing entirely on the technology (and precautionary thinking), making a blanket claim that the technology per se is risky. There is ample evidence from 50 years of risk assessment that this is not the case. What we now know is that we need to focus on the properties/characteristics of the modified (micro-) organisms, independently of the technology how these changes have been achieved. Thus, please delete the references to "greater uncertainty" and "potential uncertainty". Fine to keep the "broader scope of considerations", if that is meant to express that also the safety impact of the genetic modification needs to be assessed.
(b) Page 15: "Investigators and IBCs must consider the highest RG classification of all agents that are the source of sequences included in the construct, the PERCENTAGE of the genome contributed by each parent agent [...]" The percentage is entirely irrelevant. Considering that the whole-genome sequence of microorganisms can be fully determined, the entire focus should be on the sequences of concern. They may make up a minute contribution to the total genome size, making percentages meaningless.
(c) Page 15: "During risk assessment, it must be considered that there could be potentially new or unpredictable biosafety risks associated with an organism formed through combination of sequences from a number of organisms or due to the synergistic effect of combining transgenes that results in a new phenotype." This is speculation and should be deleted or adapted. Assessing whole-genome

sequences for sequences of concern is well established. Sure, further developments in WGS assessment will be made, and assessments accordingly refined. But there is no concrete basis to include a vague call for hypothetical hazards.
(d) Page 16: "Research involving GDMOs must be conducted at a minimum of BSL-2 containment." I do not think that this should be formulated as a sine qua non. A Risk Group 2 organism can be genetically modified to eliminate or inactivate sequences/proteins of concern. Such a GDMO would probably still be called a "biological agent" subject to the NIH guidelines, but could potentially be downgraded to BSL-1.

(2) It is regrettable that the updated guidelines should only apply to NIH-funded research. Given that the field of biosafety has matured, it would be highly desirable to have guidelines which are aligned and applicable across departments and institutions (at least) in the US.

(3) Definition of genetic modification (bottom of page 4 and top of page 5): this is an outdated definition, and does not reflect the ways of genetic engineering offered by genome editing techniques. Suggestion to rework.

More detailed comments:
(a) Scope description on page 3, point 2: suggestion to make it more consistent with point 1: "Biological agents, other than plants, that have been genetically modified;"
(b) Definition of "Genetic modification" on top of page 5: "The introduction into cells, organisms [...]". Introduction may mean physical introduction which would be misleading. Induction would seem more appropriate. Suggestion to write as follows: "The induction of stable alterations in the genome of cells, organisms, or viruses, e.g. by passaging, reassortment, chemical or radiological means".
(c) Definition of National Biosafety Data and Safety Analysis Center on page 5: unclear to me what "de-identify" should mean. Add "biosafety best practices" at the end of the definition. In addition, I would suggest to delete "metascience".
(d) Definition of wild type on page 5: suggestion to replace "introduced" by "induced" (see above).
(e) The abbreviation GDMO is currently not introduced appropriately in the document.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): No comment.

3. Continued utility of Risk Groups: In my understanding and experience, Risk Groups and Biosafety Levels serve two different purposes. Risk Groups are an important starting point, guiding the further assessment of the required biosafety levels. As done so far (and hopefully in the future), case-by-case evaluation can then be applied to determine the biosafety level required for a particular strain or activity. For instance, genetic modification, targeting sequences of concern, can result in the downgrading of the biosafety level. In contrast, genetic modification, introducing sequences of concern, may require an upgrading of the biosafety level. So, as said: very useful and important to keep.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comment.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: No comment.

6. Other feedback relevant to this resource: No comment.

306. Ali Asy

I am responding: On behalf of myself

Name: Ali Asy

Name of Organization: Animal Health Research Institute

Type of Organization: Academic Institution

Role: Other

Role - Other: Professor of Pharmacology and BRM Senior Advisor

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Animal Health Research Institute

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The expanded coverage of biohazards to include all biohazards was scientifically based, as well as reflective of the current research environment, specifically the One Health concept, which includes zoonotic and environmental agent intersections.
Although the focus was primarily on human health, the exclusion of genetically modified plants and plant pathogens that are not related to human illness may create an area of risk. Genetically modified plants and plant pathogens can have a major effect upon both ecological and agricultural biosafety, particularly when there is a possibility of gene drive or release into the environment.
Therefore, I suggest that NIH develop a low-cost notification system for this type of research so that ecological risks associated with this type of research are not left totally unmonitored, regardless of whether these risks pose direct threats to human health.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The suggested tiered review process provides the right balance between being comprehensive and being efficient. By allowing low-risk reviews (such as well-characterized cell lines, RG1 modifications) to be handled by IBC subgroups, the administrative workload will decrease while maintaining the same level of safety. Additionally, the policy should provide guidance on what documentation is required by institutions to prove that their delegated reviewers have adequate biosafety knowledge. Finally, there needs to be a way to establish mutual recognition of IBC approvals in the case of international or multi-site studies to avoid having to go through duplicate review processes that could delay important research into zoonotic diseases.

3. Continued utility of Risk Groups: The RG provides a useful baseline; however, it is static in nature and provides information regarding only wild-type agents. Because genetic modifications may unpredictably change the pathogenicity, transmissibility, or host range of an agent, the RG does not adequately address the risks associated with genetically modified organisms. Therefore, I agree with the policy's mandate to evaluate both the parent agent and the potential impact of any genetic modifications. However, the final

policy needs to clearly state that BSL is the primary metric for determining containment levels. RGs should serve as the starting point for risk assessment, but the final containment determination should be made using a comprehensive risk assessment (as described in Section V) rather than using a fixed mapping from RG to BSL. This will help avoid the false sense of security that results from assuming a modified RG2 agent is always safe at BSL-2.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary adherence to the NIH policy on biosafety will be more likely to occur with incentives as opposed to mandates. The NIH could provide some form of recognition ("Biosafety Excellence") or a simplified process for submitting grant applications to those organizations that choose to adhere to the fundamental principles of the policy, regardless of whether they receive federal funding. Providing free access to the National Biosafety Data and Safety Analysis Center (NBDSAC) for voluntary incident reporting, and explicitly guaranteeing that reported information will remain private, de-identified and used only for non-punitive purposes, would encourage institutions to report incidents. Additionally, NIH-developed peer-to-peer outreach and education programs, disseminated via professional organizations, would make it easier for institutions with limited resources to implement the best practices identified in the policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The templates are an important step toward transparency and consistency, however two improvements would increase their scientific value and the burden placed on institutions.
Incident Reporting Template:
The "lay language" requirement is an appropriate way to provide transparency to the public. However, there are times when this can result in the loss of critical technical information required by NIH to assess potential risks (e.g., precise genetic changes made, parameters used for aerosolization, or how containment systems may fail). I would suggest a two-part format: a lay summary available to the public and a technical annex that would be reviewed by NIH. If necessary, the technical annex could be labeled as confidential. This approach will allow us to achieve both transparency and maintain a high standard of scientific integrity.
The template should have a section where you can verify if institutional corrective actions were taken (e.g., when the BSO signed off or when there was a follow-up inspection). This is so that root cause analysis doesn't result in an endless series of deadlines, but instead results in completed, closed-loop corrective action. This supports the policy's emphasis on responsibility.
IBC Meeting Minutes Template:
While the template provides a comprehensive review, it may become too complex to use for delegating approvals that are routine, such as well-characterized cell lines and modifications to RG1. I would recommend using a simplified version of a consent agenda format when delegating low-risk approvals. This will allow for the continued transparency that is required, but will reduce the burden on administrators. Higher-risk or new protocols should receive more detailed narrative documentation.
The template used for reviewing gene drive modified organism (GDMO) applications must specifically state that the review process must include a justification of the ecological risk assessment rationale, which includes the documentation of off-target effects, the persistence of the organism in the environment, and the modeling assumptions, as all three of these areas represent highly uncertain issues that require greater transparency from the public, as well as an articulation of the IBC's reasoning.

6. Other feedback relevant to this resource: Additional guidance is needed in two areas: (1) emerging and zoonotic agents: The policy requires NIH approval for agents with no BMBL RG classification; however, the time frame for NIH approval is unknown. To prevent delays in conducting research related to outbreak response, it is necessary to establish an expedited review process (such as 30-60 days). (2) Gene drive modified organisms (GDMOs): Although the policy states that GDMOs require at least BSL-2 containment, the criteria used to assess ecological risks associated with GDMOs are currently unclear. NIH must develop a systematic decision tree or risk assessment matrix for GDMOs, which would include information on how to model potential off-target effects and persistence in the environment. This will allow IBCs to consistently make assessments of these uncertain projects.

Uploaded File: NIH-Guideline-Comments.docx

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

The expanded coverage of biohazards to include all biohazards was scientifically based, as well as reflective of the current research environment, specifically the One Health concept which includes zoonotic and environmental agent intersections.

Although the focus was primarily on human health, the exclusion of genetically modified plants and plant pathogens that are not related to human illness may create an area of risk. Genetically modified plants and plant pathogens can have a major effect upon both ecological and agricultural biosafety, particularly when there is a possibility of gene drive or release into the environment.

Therefore, I suggest that NIH develop a low-cost, notification system for this type of research so that ecological risks associated with this type of research are not left totally unmonitored; regardless of whether these risks pose direct threats to human health.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).

The suggested tiered review process provides the right balance between being comprehensive and being efficient. By allowing low-risk reviews (such as well characterized cell lines, RG1 modifications) to be handled by IBC subgroups, the administrative workload will decrease, while maintaining the same level of safety. Additionally, the policy should provide guidance on what documentation is required by institutions to prove that their delegated reviewers have adequate biosafety knowledge. Finally, there needs to be a way to establish mutual recognition of IBC approvals in the case of international or multi-site studies to avoid having to go through duplicate review processes that could delay important research into zoonotic diseases.

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

The RG provides a useful baseline; however, it is static in nature and provides information regarding only wild-type agents. Because genetic modifications may unpredictably change the pathogenicity, transmissibility, or host range of an agent, the RG does not adequately address the risks associated with genetically modified organisms. Therefore, I agree with the policy's mandate to evaluate both the parent agent and the potential impact of any genetic modifications. However, the final policy needs to clearly state that BSL is the primary metric for determining containment levels. RGs should serve as the starting point for risk assessment, but the final containment determination should be made using a comprehensive risk assessment (as described in Section V) rather than using a fixed mapping from RG to BSL. This will help avoid the false sense of security that results from assuming a modified RG2 agent is always safe at BSL-2.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).

Voluntary adherence to the NIH policy on biosafety will be more likely to occur with incentives as opposed to mandates. The NIH could provide some form of recognition ("Biosafety Excellence") or a simplified process for submitting grant applications to those organizations which choose to adhere to the fundamental principles of the policy, regardless of whether they receive federal funding. Providing free access to the National Biosafety Data and Safety Analysis Center (NBDSAC) for voluntary incident reporting, and explicitly guaranteeing that reported information will remain private, de-identified and used only for non-punitive purposes, would encourage institutions to report incidents. Additionally, NIH-developed peer-to-peer outreach and education programs, disseminated via professional organizations, would make it easier for institutions with limited resources to implement the best practices identified in the policy.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.

The templates are an important step toward transparency and consistency, however two improvements would increase their scientific value and the burden placed on institutions.

Incident Reporting Template:

The "lay language" requirement is an appropriate way to provide transparency to the public. However, there are times when this can result in the loss of critical technical information required by NIH to assess potential risks (e.g., precise genetic changes made, parameters used for aerosolization, or how containment systems may fail). I would suggest a two-part format: a lay summary available to the public and a technical annex that would be reviewed by NIH. If necessary, the technical annex could be labeled as confidential. This approach will allow us to achieve both transparency and maintain a high standard of scientific integrity.

The template should have a section where you can verify if institutional corrective actions were taken (e.g., when the BSO signed off or when there was a follow-up inspection). This is so that root cause analysis doesn't result in an endless series of deadlines, but instead results in completed, closed-loop corrective action. This supports the policy's emphasis on responsibility.

IBC Meeting Minutes Template:

While the template provides a comprehensive review, it may become too complex to use for delegating approvals that are routine, such as well characterized cell lines and modifications to RG1. I would recommend using a simplified version of a consent agenda format when delegating low-risk approvals. This will allow for the continued transparency that is required, but will reduce the burden on administrators. Higher risk or new protocols should receive a more detailed narrative documentation.

The template used for reviewing gene drive modified organism (GDMO) applications must specifically state that the review process must include a justification of the ecological risk assessment rationale, which includes the documentation of off-target effects, the persistence of the organism in the environment, and the modeling assumptions, as all three of these areas represent highly uncertain issues that require greater transparency from the public, as well as an articulation of the IBC's reasoning.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Additional guidance is needed in two areas: (1) emerging and zoonotic agents: The policy requires NIH approval for agents with no BMBL RG classification; however, the time frame for NIH approval is unknown. To prevent delays in conducting research related to outbreak response, it is necessary to establish an expedited review process (such as 30-60 days). (2) gene drive modified organisms (GDMOs): Although the policy states that GDMOs require at least BSL-2 containment, the criteria used to assess ecological risks associated with GDMOs are currently unclear. NIH must develop a systematic decision tree or risk assessment matrix for GDMOs, which would include information on how to model potential off-target effects and persistence in the environment. This will allow IBCs to consistently make assessments of these uncertain projects.

307. Debbie Eckert

I am responding: On behalf of myself

Name: Debbie Eckert

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: It would be helpful to have an expanded explanation of the intended scope of the policy, including examples of research within scope and outside of scope. As written, the scope is not entirely clear.

The beginning of the explanation of the scope of the policy indicates it "covers all biomedical research, in laboratory settings, involving biohazards." Is research using a tool described later in the scope (e.g., a genetically modified organism), in the lab, but with non-biomedical focus and non-NIH funding (e.g., environmental studies funded by NSF) considered outside of scope? One such example could be the study of the microbiome of a mammal, including genetic manipulation of said microbiome, to determine the impact on metabolism and survival in climate extremes.

The remaining definition of the scope in the policy is: "research involving … known or potential risk to human health and any of the following:
1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above."

Does the scope of covered research have to have a known or potential risk to humans AND be included on the list below? What if it is only one or the other? Or does the scope imply that anything on the numbered list could have a potential risk to humans? i.e., Is there flexibility for institutions to perform risk assessments to determine what requires IBC review? e.g., If the institution decides a genetically modified organism housed at ABSL1 is not a potential risk to human health, can their IBC decide it is outside of the scope of the policy and decline to review it?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): One of the primary objectives stated throughout the modernization effort was to expand oversight of higher-risk activities while simultaneously reducing unnecessary burden for low-risk research. Indeed, the introduction in the draft indicates the removal of "red tape for low-risk research." The draft successfully broadens oversight

to include many biological hazards beyond recombinant and synthetic nucleic acid technologies; however, it is less clear how the proposal reduces burden for lower-risk activities.

RG1 wild-type agents are excluded, but RG1 derivatives and other low-risk materials are included. These include:
• genetically modified RG1 agents, with an expansive definition for genetic modification;
• transgenic organisms at BSL-1/ABSL-1;
• plasmids with low-risk inserts;
• replication-incompetent, non-integrating viral vectors;
• well-characterized cell lines; and
• non-Select Agent toxins.

While the ability to use delegated review is a welcome addition, requiring it for low-risk activities will likely increase review and documentation requirements (for researchers as well as IBC delegates).

A gap analysis at our institution indicates we will have to invest substantial effort into identifying low-risk research that is not currently covered under the NIH guidelines but will be covered under the new policy. I do not believe this is the intent of the new policy, and request that research that can be safely conducted at BSL1 containment be exempt from the policy entirely. This will allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval. When the dominant interaction between biosafety professionals and researchers involves cataloguing low-risk biological agents, administrative fatigue decreases cooperation and buy-in for the more impactful, higher-risk research.

Along the same lines, the proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public posting of all incident reports using the required template including PI names and funding details could expose personal information, lead to security concerns, and substantially damage a strong reporting culture. At our institution, it could reverse our years' long effort to improve laboratory safety culture, including near-miss reporting. Some research areas are prone to security concerns for researchers, where identification, even generally, could put their personal safety at risk. In many small laboratories, the details contained in the required template could easily lead to identifying specific individuals involved in the incident, violating privacy concerns and in some cases HIPAA protected information.

The effort to gather incident data and provide actionable transparency in laboratory safety practice is noteworthy. I suggest these goals could be achieved with anonymized, aggregated public reporting.

6. Other feedback relevant to this resource: As the approval of an institutional Biosafety Assurance is an entirely new step in IBC operation, please provide additional implementation guidance regarding the process, including examples and/or suggested templates, the expected timeline, and the criteria for approval.

The proposed six-month effective date for implementation will place an unrealistic burden on research institutions and set them up for non-compliance from day one. The research community is supportive of oversight modernization and wants to be a partner in the process. Please allow us the time that will be required to realistically reach compliance with an entirely new oversight paradigm. Some of the tasks that will be required for complying include: inventorying newly covered research, obtaining an approved Biosafety Assurance, revising written institutional policies, redesigning electronic systems, and training researchers, administrators and the IBC. Please provide at least 24 months after publication of the final policy and complete implementation materials.

Uploaded File: DME-final-comments-on-NIH-Draft-Biosafety-Policy.docx

Thank you for the substantial effort dedicated to modernizing biosafety oversight and for the opportunity to provide comments on the published Draft NIH Biosafety Policy for Research Involving Biohazards. Although I am the Biosafety Officer at the University of Utah, these comments represent my personal opinion, and they should not be interpreted to be representative of the views of the University of Utah. I applaud the meaningful progress in proposed oversight which is demonstrated by the expansion beyond recombinant and synthetic nucleic acid research to wild type human pathogens and biological toxins, as well as the addition of a delegated IBC review tier.

At the same time, the proposed policy would substantially expand review, documentation, public-posting, assurance, and reporting obligations. The result will be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions, which is contrary to the stated objective of "removing red tape for low-risk research."

Below I provide constructive criticism that I hope will be considered for the next draft of the new policy. Additionally, due to the request for substantial changes in the final requirements, I request you will **provide an opportunity for public review and comment on the next draft before it is finalized.**

Topic: SCOPE

It would be helpful to have an expanded explanation of the intended scope of the policy, including examples of research within scope and outside of scope. As written, the scope is not entirely clear.

The beginning of the explanation of the scope of the policy indicates it "covers all biomedical research, in laboratory settings, involving biohazards." Is research using a tool described later in the scope (e.g., a genetically modified organism), in the lab, but with non-biomedical focus and non-NIH funding (e.g., environmental studies funded by NSF) considered outside of scope? One such example could be the study of the microbiome of a mammal, including genetic manipulation of said microbiome, to determine the impact on metabolism and survival in climate extremes.

The remaining definition of the scope in the policy is: "research involving … known or potential risk to human health and any of the following:

1. Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above."

Does the scope of covered research have to have a known or potential risk to humans AND be included on the list below? What if it is only one or the other? Or does the scope imply that anything on the numbered list could have a potential risk to humans? i.e., Is there flexibility for institutions to perform risk assessments to determine what requires IBC review? e.g., If the institution decides a genetically modified organism housed at ABSL1 is not a potential risk to human health, can their IBC decide it is outside of the scope of the policy and decline to review it?

Topic: STREAMLINING OF ADMINISTRATIVE BURDEN

One of the primary objectives stated throughout the modernization effort was to expand oversight of higher-risk activities while simultaneously reducing unnecessary burden for low-risk research. Indeed, the introduction in the draft indicates the removal of "red tape for low-risk research." The draft successfully broadens oversight to include many biological hazards beyond recombinant and synthetic nucleic acid technologies; however, it is less clear how the proposal reduces burden for lower-risk activities.

RG1 wild-type agents are excluded, but RG1 derivatives and other low-risk materials are included. These include:
• genetically modified RG1 agents, with an expansive definition for genetic modification;
• transgenic organisms at BSL-1/ABSL-1;
• plasmids with low-risk inserts;
• replication-incompetent, non-integrating viral vectors;
• well-characterized cell lines; and
• non-Select Agent toxins.

While the ability to use delegated review is a welcome addition, requiring it for low-risk activities will likely increase review and documentation requirements (for researchers as well as IBC delegates).

A gap analysis at our institution indicates we will have to invest substantial effort into identifying low-risk research that is not currently covered under the NIH guidelines but will be covered under the new policy. I do not believe this is the intent of the new policy, and **request that research that can be safely conducted at BSL1 containment be exempt from the policy entirely**. This will allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval. When the dominant interaction between biosafety professionals and researchers involves cataloguing low-risk biological agents, administrative fatigue decreases cooperation and buy-in for the more impactful, higher-risk research.

Along the same lines, the proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and **assign oversight based on the resulting phenotype and risk.**

Topic: SCOPE OF PUBLIC INCIDENT REPORTING

Public posting of all incident reports using the required template including PI names and funding details could expose personal information, lead to security concerns, and substantially damage a strong reporting culture. At our institution, it could reverse our years' long effort to improve laboratory safety culture, including near-miss reporting. Some research areas are prone to security concerns for researchers, where identification, even generally, could put their personal safety at risk. In many small laboratories, the details contained in the required template could easily lead to identifying specific individuals involved in the incident, violating privacy concerns and in some cases HIPAA protected information.

The effort to gather incident data and provide actionable transparency in laboratory safety practice is noteworthy. I suggest these goals could be achieved with anonymized, aggregated public reporting.

Topic: IMPLEMENTATION TIMELINE

The proposed six-month effective date for implementation will place an unrealistic burden on research institutions and set them up for non-compliance from day one. The research community is supportive of oversight modernization and wants to be a partner in the process. **Please allow us the time that will be required to realistically reach compliance with an entirely new oversight paradigm.** Some of the tasks that will be required for complying include: inventorying newly covered research, obtaining an approved Biosafety Assurance, revising written institutional policies, redesigning electronic systems, and training researchers, administrators and the IBC. Please provide at least 24 months after publication of the final policy and complete implementation materials.

Topic: IMPLEMENTATION GUIDANCE

As the approval of an institutional Biosafety Assurance is an entirely new step in IBC operation, please provide additional implementation guidance regarding the process, including examples and/or suggested templates, the expected timeline, and the criteria for approval.

Thank you again for your continued leadership in advancing and modernizing biosafety oversight. I appreciate NIH's engagement with the biosafety community and hope we can work together to ensure that the final policy is clear, allows the allocation of resources based on risk, and is effective in supporting both scientific progress and the safety of researchers and

Description: Dana-Farber Cancer Institute supports the draft NIH biosafety policy overall but urges revisions to public incident-report posting requirements to protect disclosure, reduce reputational harm, and exempt certain lower-risk incidents, while endorsing confidential near-miss reporting through NBDSAC.

DFCI Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards, Notice Number NOT-OD-26-112

Dear NIH Office of Science Policy:

Dana-Farber Cancer Institute (Dana-Farber) appreciates the opportunity to comment on the draft policy, *NIH Biosafety Policy for Research Involving Biohazards*. Dana-Farber is an NCI-designated comprehensive cancer center and a teaching affiliate of Harvard Medical School. Our mission is to deliver expert and compassionate care while advancing the science of cancer—improving understanding, diagnosis, treatment, cure, and prevention of cancer and related diseases. We are proud to be a global leader in cancer research, diagnostics, and clinical care. Dana-Farber is also a proud and longstanding partner of the federal government in U.S. scientific innovation and biomedical advancement. As you know, like other research institutions across the country, research conducted at or sponsored by Dana-Farber is subject to federal, state, local, and institutional biosafety requirements. The Dana-Farber Institutional Biosafety Committee (IBC) provides centralized biosafety review and oversight for biological research conducted at or sponsored by the institution.

Dana-Farber supports the draft policy, *NIH Biosafety Policy for Research Involving Biohazards*, which would strengthen institutional biosafety programs. The draft policy is consistent with the current policies and procedures of Dana-Farber's IBC, and its Environmental Health & Safety Office of Biosafety, which identifies biological safety practices, procedures, facility construction, and operational standards for the safe handling and use of biohazardous materials. Dana-Farber leadership supports the Office of Biosafety in its implementation of a risk-based and evidence-based approach to oversight of basic and clinical research involving biological materials.

We respectfully request that the NIH Office of Science Policy consider the following comments in its revision of the draft policy.

With regard to public posting of IBC minutes, Dana-Farber's IBC already publicly posts minutes of its convened committee meetings and Dana-Farber expects to be able to comply with the draft minutes template. However, Dana-Farber is concerned about the public posting of incident reports as this practice may discourage the institutional workforce from disclosing actual incidents, accidents, and near misses. Furthermore, the public posting of incident reports may create reputational harm for the Principal Investigator (PI). Dana-Farber therefore recommends revision of the incident report template to exclude the name of the PI, or alternatively, NIH allow redaction of this information. Dana-Farber further recommends exempting lower-risk incidents involving

BSL-1/ABSL-1 or certain BSL-2/ABSL-2 work from the requirement for public posting. The IBC must review certain lower-risk incidents described below:

1. Any incident involving research subject to the policy with an animal that is housed at BSL-1/ABSL-1 or BSL-2/ABSL-2 (e.g., bite, scratch, escape or improper disposition); or
2. Any incident at BSL-1/ABSL-1 or BSL-2/ABSL-2 that does not involve agent-specific medical treatment when first aid is administered.

Such lower-risk incidents do not require reporting to the NIH and are instead evaluated by the Environmental Health & Safety Office of Biosafety. These incidents are presented to the IBC for discussion and documented in the publicly posted minutes of the IBC meetings, so there is limited benefit of publicly posting separate reports of these lower-risk incidents, particularly given the potential to discourage the institutional workforce from disclosing actual incidents, accidents, and near misses, as well as the potential for reputational harm. Additionally, it should be clarified that minor spills of low-risk agents, that do not involve a breach of containment and that were properly cleaned and decontaminated, generally are not subject to the incident report requirements, including public posting.

Dana-Farber supports the draft policy's recommendations that institutions "submit voluntary, confidential reports regarding near-misses, secondary failures, or procedural issues to the National Biosafety Data and Safety Analysis Center (NBDSAC)." The proposed NBDSAC provides a more appropriate framework for public transparency and for analysis by biosafety practitioners in a non-punitive manner. The capability of the NBDSAC to aggregate and de-identify data will support subsequent analysis to identify recurring hazards, contributing factors, corrective actions, and national trends while minimizing potential harm to individual workforce members, principal investigators, or institutions that could result from incident-specific public reporting.

309. Peter K. Rogan

I am responding: On behalf of myself

Name: Peter K. Rogan

Name of Organization: Cytognomix

Type of Organization: Commercial Entity (Biotech/Device/Pharmaceutical Company/Small Business)

Role: Organizational Official

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Genomics bioinformatics

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy incorrectly states that altering the expression of genes for example mRNA therapies is covered by genetic modification. Altering gene expression is transient, unlike gene modification which is effectively permanent. Furthermore, many compounds or other environmental stimuli can alter gene expression without altering a genome.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): None

3. Continued utility of Risk Groups: Not applicable

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Don't redefine this policy in such a way that it is no longer scientifically compliant.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: None

6. Other feedback relevant to this resource: None

310. John McCarthy

I am responding: On behalf of myself

Name: John McCarthy

Name of Organization: Countermeasures Research

Type of Organization: Other

Type of Organization - Other: Analysis and Research

Role: Investigator/Researcher

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Medical countermeasures (antifungal and antiviral drug development); biosecurity.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: This comment supports basing the scope on biohazards rather than genetic modification and also recommends recognizing overlap with existing federal oversight and addressing an oversight gap.

The Policy should recognize that clinical specimens are already under federal oversight. A CLIA-certified diagnostic laboratory conducting research on patient blood under an IRB-approved protocol operates under the OSHA bloodborne pathogens standard and under the facility and safety requirements of its CLIA certification, and its practices and records are subject to inspection. Section IV-2 of the Policy nonetheless requires IBC review before initiating “Research with primary cells that may be contaminated by adventitious agents,” and patient blood can meet that description. The draft’s other-agency provision already allows such research to “proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained.” The Policy should name the OSHA bloodborne pathogens standard, as applied in a CLIA-certified laboratory, as oversight that qualifies, so that an IRB-approved study that handles and tests patient blood in a CLIA-certified laboratory under universal precautions is not also subject to an IBC review that duplicates any protections those programs already require. Culturing or propagating patient cells would remain under Section IV-2.

Proposed text, as an addition to the other-agency provision in Section II: "Research in which human clinical specimens are handled and tested in a CLIA-certified laboratory under the OSHA bloodborne pathogens standard, 29 CFR 1910.1030, is research under the purview of another federal agency for purposes of this provision. Culture or propagation of such specimens remains subject to Section IV-2."

The Policy should also address an oversight gap regarding genetically modified plants. The draft excludes them from the definition of biohazard, “Cells, viruses, or organisms, other than plants, that have been genetically modified,” and from Section IV-2. Appendix P of the current NIH Guidelines sets containment requirements for that work. The new Policy is expected to supersede the Guidelines and retain content

from Appendices B and G-II-C-5, but it does not currently address Appendix P. USDA review under 7 CFR part 340 covers the import, interstate movement, and environmental release of regulated plants, not contained laboratory work. The draft already directs IBCs to weigh harm to “the environment.” Rather than suggesting that the NIH adopt agricultural oversight, this comment suggests clarifying what will replace Appendix P for contained work with genetically modified plants at NIH-funded institutions.

Proposed text: "Contained laboratory and greenhouse research with genetically modified plants at institutions under this Policy will adhere to the containment practices of Appendix P of the NIH Guidelines, maintained as an implementation resource."

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): This comment supports the proposed three-tier (federal, institutional, and investigator) system calibrated to research risk and suggests further consideration of accountability and the administrative burden on small awardees.

The Policy does not define "institution." Its General Definitions cover Biosafety Assurance, the IBC, laboratory research, and NIH-supported research, but not the entity that bears the obligations. The obligations state that institutions must "establish an IBC" of "at least five members," include "at least two members who are not affiliated with the institution"; train principal investigators and "laboratory staff"; post minutes and incident reports "on a public-facing webpage on the website of the institution"; and have their biosafety officer or designated official conduct "periodic inspections to ensure that laboratory biocontainment facilities and equipment are functioning properly." These obligations describe an institution that operates its own laboratory facility, such as a university, a medical center, or an established company. However, early-stage start-up biotechnology companies often do not. They have a few employees, rent bench space in a shared laboratory run by an incubator, and outsource work to universities and contract research organizations.

Recommendation: Define "institution" and distinguish the awardee from the institution conducting the research.
Proposed text for the definition: "Institution: the legal entity that operates the facility in which research subject to this Policy is conducted, or that sponsors such research."

The obligations, as written, are disproportionate for small start-ups with few employees and a limited budget, and run counter to the draft’s own criterion of “streamlining of administrative burden.” Under the draft, “no research within the scope of this Policy is conducted until approved by the IBC, or IBC delegate,” so whatever its risk level, the work is reviewed where it is done; a second committee at the awardee would add burden and duplicate that review. The draft as written also applies to small start-ups as “an institution that receives any NIH funding,” which can be interpreted in two different ways. Under one interpretation, the Assurance comes from “the institution conducting the research,” which places it with the university or contract laboratory where the work is done. Under the other, the awardee is itself an institution that must “establish an IBC” and ensure that research “conducted at or sponsored by the institution, irrespective of the source of funding” complies. The draft does not clarify or choose between the two, and its templates set rules for an externally administered IBC that the Policy mentions once and does not define. Under the second interpretation, a start-up with one SBIR or STTR Phase I award must hold its own Assurance and a five-member IBC for every project, including privately funded ones. A five-

member committee with two unaffiliated members can be larger than the small start-up and would require it to meet the external committee requirement, with resources from a Phase I budget. That payment would buy a second review of work that the IBC of the institution where it is performed would approve. The split is not the start-up's choice: under an STTR award, the statute requires at least 30 percent of the work be performed at the research institution, so the split between the awardee and the laboratory is a matter of program design.

Recommendation: Every institution should still file its own Assurance so NIH maintains a signed commitment from each awardee it funds. However, awardees whose research is conducted at an institution holding an NIH-approved Assurance should be allowed to meet their obligations through that institution. The awardee's Assurance would document a written reliance agreement under which the performing institution's IBC and biosafety program review and oversee the work, and the agreement would assign incident reporting and posting to the institution where the work is performed. This mirrors IRB policy for human subjects research: institutions keep their own Assurance, with a single review board. When a start-up rents bench space in a shared laboratory run by an incubator, the Policy should clarify responsibility for the Assurance, the IBC, and any reliance agreement.

Proposed text for reliance: "An institution that sponsors research performed at another institution holding an NIH-approved Biosafety Assurance may satisfy Section III-A for that research by documenting, in its own Assurance, reliance on the performing institution's IBC and biosafety program under a written reliance agreement."

Three further recommendations. First, set a period within which NIH will act on a new Assurance: Phase I awards run up to twelve months, and the current draft does not address this. Second, companies can hold multiple awards; an NIH STTR alongside Department of Defense or BARDA awards, and Department of Defense award terms already require adherence to the NIH Guidelines. The draft can indicate whether such terms fall under the "regulation or purview of another federal agency," and NIH can work with those agencies so their terms reference this Policy from the same effective date; otherwise, a laboratory can be held to multiple guidelines by different funders. Third, contract research organizations and incubator laboratories may not have NIH funding and therefore not hold an Assurance for an awardee to rely on. NIH could offer voluntary Assurances to institutions performing research for NIH-funded sponsors without receiving NIH funding themselves.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: If the intent of the policy is to expand oversight for meaningful biosafety risks while avoiding unnecessary administrative burden for routine, low-risk work, the draft should be revised to better align its requirements with that objective. As currently written, the policy could substantially expand institutional review, documentation, reporting, and public-posting obligations for materials and activities that may present minimal biosafety risk. NIH should establish appropriate exemptions, administrative registration pathways, or other mechanisms for clearly defined low-risk activities.

Several important terms appear to be undefined or insufficiently precise. Clear and internally consistent definitions are needed for terms such as “biohazard,” “biological agent,” “genetic modification,” “biomedical research,” “toxin,” and “genetically modified organism.” Clear definitions are essential to ensure consistent institutional determinations and risk-based application of the policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: NIH-Comment.pdf

Subject: Support for CSHEMA Recommendations on the Draft NIH Biosafety Policy

To Whom It May Concern:

I am submitting this comment in response to NIH's request for public comment on the Draft NIH Biosafety Policy for Research Involving Biohazards, issued under NOT-OD-26-112.

I support the comment submitted by the **Campus Safety, Health, and Environmental Management Association (CSHEMA)** regarding this effort. CSHEMA's comment appropriately reflects the needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

As an environmental health and safety professional working in higher education, I support CSHEMA's recommendations and would like to amplify the following key points that I believe warrant particular attention:

- **Definitions:** Several important terms appear to be undefined or insufficiently precise. Clear and internally consistent definitions are needed for terms such as "biohazard," "biological agent," "genetic modification," "biomedical research," "toxin," and "genetically modified organism." Clear definitions are essential to ensure consistent institutional determinations and risk-based application of the policy.
- **Scope and risk calibration:** If the intent of the policy is to expand oversight for meaningful biosafety risks while avoiding unnecessary administrative burden for routine, low-risk work, the draft should be revised to better align its requirements with that objective. As currently written, the policy could substantially expand institutional review, documentation, reporting, and public-posting obligations for materials and activities that may present minimal biosafety risk. NIH should establish appropriate exemptions, administrative registration pathways, or other mechanisms for clearly defined low-risk activities.
- **Protect Personal Information:** As written, the incident report template raises privacy concerns for exposed individuals and would likely discourage reporting. Please allow public reporting that does not include information on the lab or role of the individual involved.
- **Second review opportunity:** Given the potential extent of revisions needed to address the concerns raised by CSHEMA and others, NIH should provide a second public review and comment period after substantial revisions are made and before the policy is finalized. A second review would allow stakeholders to evaluate how the revised definitions, scope, oversight categories, reporting requirements, and implementation provisions operate together.
- **Implementation timeline:** The proposed six-month implementation period is not sufficient for institutions to assess newly covered research, revise policies and procedures, update review and reporting systems, train affected personnel, obtain institutional approvals, and secure necessary resources. I support CSHEMA's recommendation for a minimum 24-month phased implementation period and believe that, given the breadth of the proposed changes, a three-year implementation period would be more realistic.

I also encourage NIH to engage representatives from CSHEMA or ABSA International while updating the draft policy to provide real-time feedback on changes that are being made.

Thank you for the opportunity to comment.

312. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Other

Type of Organization - Other: Biosafety Professional

Role: Organizational Official

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Expansion of the scope is helpful in addressing biohazards more broadly but the policy is inconsistent about the applicability of human, animal, and plant health impacting organisms and oversight. The definition of biohazards is not well defined. Many definitions in the document are lacking, unclear, or incorrect/incomplete.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Requiring an incident reporting template and meeting minutes template do not allow for flexibility in how organizations may collect and investigate these situations. Inclusion of personally identifiable information in the incident reporting template (like PI name and position title of involved individuals) and the requirement for it to be publicly available (not just submitted to NIH) will lead to underreporting of incidents which can negatively impact safety. Research security is also a concern for publicly reporting so much information about activities and their locations. Aggregated information should be compiled and reported as such, more akin to the way that the Public Health Agency of Canada (PHAC) does their incident reporting.

6. Other feedback relevant to this resource: 6 months for implementation is categorically insufficient especially for large organizations with large research programs especially those that have not been fully

covered by this expanded policy scope. Any required documentation/submissions should have templates as a starting point that are allowed to be modified so long as they contain the required information.

Uploaded File: NIH-comments.pdf

Firstly, I would like to thank the NIH for the opportunity to submit comments on the Draft NIH Biosafety Policy for Research Involving Biohazards. This policy has broad impact across organizations that handle biological materials and receive NIH funding, and the involvement of the regulated community is a welcome addition to the policymaking process.

This document is a good first draft policy however many changes are needed to make it acceptable to the regulated community and therefore I would suggest another draft after revisions and round of public comments would be appropriate.

I fully support the comments submitted by both CSHEMA on October 12th, 2026, and ABSA International dated October 19th, 2026, and am therefore incorporating them in their entirety by reference into my response.

The expanded scope is appreciated as it provides more coverage of biological hazards that are worked with in laboratory settings. However, not requiring that organizations have Biosafety Officers with institutional responsibilities and authority is short-sighted and impacts the ability of the IBC to evaluate risk associated with biohazards. This is also an unfunded mandate that requires a large administrative burden on the EHS/HSE office and the BSO and does not unfortunately elevate the IBC to level of institutional importance of an IACUC or IRB committee. Biosafety and biocontainment are critically important in organizations and needs to be treated as such by requiring trained and competent professionals be included in all biohazard risk assessments and regulatory oversight.

Requiring an incident reporting template and meeting minutes template do not allow for flexibility in how organizations may collect and investigate these situations. Inclusion of personally identifiable information in the incident reporting template (like PI name and position title of involved individuals) and the requirement for it to be publicly available (not just submitted to NIH) will lead to underreporting of incidents which can negatively impact safety. Research security is also a concern for publicly reporting so much information about activities and their locations. Aggregated information should be compiled and reported as such, more akin to the way that the Public Health Agency of Canada (PHAC) does their incident reporting.

Allowing for only 6 months for implementation is categorically insufficient especially for large organizations with large research programs especially those that have not been fully covered by this expanded policy scope.

Thank you again for this opportunity and I hope that we are able to see another draft before finalization of this critically important, wide-reaching biosafety policy.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Immunology and Inflammatory Bowel Diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definition of Genetic modification includes nucleic acid molecules that "can be transcribed or translated." Read together with Section II.2, which brings "cells, viruses, or organisms, other than plants, that have been genetically modified" into scope, this classifies any cell transfected with synthetic mRNA, siRNA, or a transient expression plasmid as a biohazard.

This is scientifically inaccurate, and I believe it is unintended. Three of the four criteria depend on stability or replication—including the fourth, which expressly requires "stable alterations into the genome." The third has no such limiter. Transfected mRNA alters no genome: it does not enter the nucleus, is not replicated, is not heritable, and is degraded within days. What changes is the proteome, transiently. As written, the criterion would equally capture any agent that alters transcription.

The practical consequence is substantial. The draft includes no equivalent to Section III-F-1 of the current NIH Guidelines, which exempts synthetic nucleic acids that can neither replicate nor integrate and do not encode a potent toxin. Section IV-3 instead routes to delegated review work that is exempt today, including "plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes" and "well-characterized cell lines." For a research division of moderate size this converts a large volume of routine, genuinely low-risk work into registered protocols — contrary to the policy's stated aim of removing red tape for low-risk research.

Recommendation. Amend the third criterion to read: "Can be transcribed or translated to yield a toxin, virulence factor, or select agent product, or a product meeting the criteria above." Alternatively, add an exempt category below Section IV-3 for non-replicating, non-integrating nucleic acids that do not encode such products. Either approach preserves NIH's coverage of hazardous encoded products without asserting that a transiently transfected cell has been genetically modified.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The new addition that genetic modification also relates to being "transcribed or translated" while the genome is not altered is too broad in my view. In most cases this does not alter the cells (genome) permanently and I think this would lead to an overregulation with severe consequences for research and technology that is highly beneficial to humans e.g. for their health. I could follow a logic that being "transcribed or translated" needs to be considered more, if the product yields a modification on the genome that can be inherited and replicated upon division. However, such path to such genetic modification would already be captured with the other categories.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): RNA Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Currently, definitions of genetic modification require a permanent change to the genetic material of the host cell or organism, for example modification of their genomic DNA (or genomic RNA for select viruses). The new policy language would reclassify any nucleic acid that “Can be transcribed or translated”, including most transiently introduced transfected plasmids, exogenous mRNAs, and several vaccine technologies as a "genetic modification". This re-classification could lead to confusion, misunderstanding, and loss of public trust in routine RNA research and in recombinant vaccine technologies, with potentially devastating public health outcomes.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): This is fine

3. Continued utility of Risk Groups: If it isn’t broken, don’t fix it!

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Waste of time.

Uploaded File: 4-Biosafety-Policy-Comments-to-NIH-OSP.docx

Description: high-level comments regarding Policy Draft

Priority requests to NIH OSP Regarding Biosafety Policy Draft

- **<u>Define the minimum requirements for an Instutional Biosafety Program.</u>**

  1. Partial quote: '*. . . the National Institutes of Health (NIH) is committed to ensuring that* ***gold-standard science*** *is conducted under* ***gold-standard biosafety conditions****.*"
  A single, egregious oversite is that the requirement for a "Biosafety Officer" defaults to that listed in the current NIH Guidelines. How can an institution empower and run a "**gold-standard biosafety program"** without mandating a program lead that has significant biosafety experience?

  2. Pick a consistent title for the policy that reflects what the NIH wants / needs: Is this a "Biosafety Policy", a "Biosafety & Biosecurity Policy", or a "Policy for work with Biohazards"? Each of the titles will be interpreted differently by institutional leadership.
  This is important because the draft title "***Biosafety Policy for Research Involving Biohazards"*** (Biosafety & Biosecurity Policy?) does not address the fact that biosafety programs include a comprehensive administrative portfolio that includes research safety, compliance, ethics, training, committee review, and approval portfolio.

  3. Define what level of institutional empowerment must be granted to the Biosafety & Biosecurity program. Must both components be supported or is either one, biosafety or biosecurity, adequate to satisfy this policy?
  A biosafety officer or biosafety professional overseeing this gold standard biosafety program must be granted administrative level empowerment equivalent to the "Director of Animal Welfare", Director of Human Research Protections" or the "Institutional Veterinarian". A more appropriate role, to accomplish what the NIH is striving toward, will be Assistant or Associate Vice Provost or Vice President for Biosafety & Biosecurity Programs. Someone at the institutional leadership level, with appropriate biosafety experience, must be empowered to oversee these programs. **This must be mandated by the policy or it won't happen.** Lack of this empowerment is currently what fails many biosafety programs.

- **<u>Codify the Institutional Biosafety Committee (IBC)</u>**

  1. Define what level of institutional support is adequate to satisfy policy requirements. Must Institutional resources include similar administrative structure for the IBC that is offered to the IRB and/or IACUC? What is the minimum? Office

space, administrative support adequate for the number of IBC committees (or sub-committees), Leadership team consisting of Director, Associate Director, Professional staff separate from the biosafety program? For example, the Director of the IBC office has a separate role from Institutional Biosafety Officer, etc.? The Biosafety Officer sits as a voting member only?

- **Fully Embrace Risk-Based Biosafety**

  1. It is stated that this policy intends to encourage and embrace risk-based oversight and reporting. Yet, the only risk criteria incorporated into this first draft are Biological Agent Risk Groups and Biosafety Levels. These criteria are not applicable to all life science research activities or agents proposed for enhanced biosafety oversight. For example, biologics used in clinical trials cannot be defined by a biological agent Risk Group. Biologics are typically risk assessed by Risk Banding. Include/acknowledge this aspect of risk assessment in the updated draft. Alternatively, allow the biosafety professionals overseeing biosafety programs the freedom to perform risk assessment without specifying the risk criteria that must be used, because in biosafety and especially because of rapidly developing life sciences research programs, "it depends". Please let life science research professionals do what they do best, without restriction.

Uploaded File: 3-NIH-Biosafety-Policy-Comments.docx

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public confidence in NIH-supported science. I offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

Topic to Address*: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any

resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.

3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory

rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:
    a. the nature and stability of the genomic modification;
    b. whether the modification is heritable and the potential for transmission through breeding;
    c. effects on animal health, phenotype, host range, susceptibility, or disease;
    d. potential entry into breeding or food-production systems;
    e. potential environmental release or interaction with non-research animal populations;
    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and
    g. applicable federal, state, or other regulatory oversight.
2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.
3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.
4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

  deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the

Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

b. State explicitly that the Policy does not address non-biological hazards.

c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

  Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

  the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate, and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

  Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and

Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

I believe the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, I request that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, I welcome the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. I do not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. I recommend that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice

- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, I recommend a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with my earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*
- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. I recommend that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior

leadership;

2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply

another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.
NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, I kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. I encourage NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE

BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The

Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While I support appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes
6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions

throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as “any incident,” “loss of containment,” “significant problems,” and “minor spills... generally do not need to be reported,” and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report “potential releases involving facility and/or equipment failures even when redundant systems were functioning properly” would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure

in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: I recommend the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and

occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. I support preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

319. N/A

Comment to NOT-OD-26-112

I appreciate NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions.

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk

and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under

the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure,"

“compliance violation,” and “minor spill.” The policy should clarify whether precautionary post exposure prophylactic treatment is considered “agent-specific treatment”. It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

5. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures,

workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

Recommend that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

Uploaded File: 1-Recommendations-to-the-NIH-OSP.docx

I ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

1. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts;

compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

2. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure

implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological

exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

3. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

4. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

5. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

6. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and

explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

7. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions.

Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: NIH's goal of modernizing biosafety oversight and expanding oversight beyond recombinant and synthetic nucleic acid research is commendable. However, the proposed scope is broader than necessary and would likely capture substantial amounts of routine, low-risk research without a clear idea of additional biosafety benefit. The definition of biohazards and the categories of research subject for oversight must be defined appropriately to help differentiate work scope, which is true biosafety risk from activities that are well characterized, routine, or adequately addressed through existing institutional controls.

The current scope will most likely and inadvertently create several administrative challenges:
• Expansion of IBC review to routine low-risk activities will divert or dilute institutional resources (these are finite resources) away from higher-risk research requiring greater biosafety scrutiny.
• The draft policy does not clearly distinguish research from diagnostic testing, assay development, quality assurance activities, method validation, or other operational laboratory functions, creating uncertainty regarding applicability.
• The policy applies broadly to all NIH-funded institutions, directly or indirectly through sub-contracts or other contract mechanisms. There will be high variability in interpretation and implementation across institutions.

Recommendation: NIH should establish clearer exclusion, exemption, notification, and/or registration categories for well-characterized, minimal-risk activities and provide examples illustrating what research falls within and outside the scope of the policy. This would improve consistency while preserving oversight of genuinely higher-risk research.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered oversight framework is appropriate and necessary. The concept that oversight requirements should be proportional to risk and uncertainty is appreciated. However, the proposed framework does not adequately distinguish between high-risk, moderate-risk, and routine low-risk activities. Although the draft includes delegated review pathways for certain lower-risk activities, significant administrative requirements are tied with protocol review, documentation, approval tracking, renewals, reporting,

public posting, and record retention. As a result of this draft policy, delegated review will affect committee discussion time without substantially reducing overall institutional burden.

Recommendation:
Reserve full IBC review for research involving novel hazards, significant uncertainty, elevated containment requirements, or substantial modifications to biological agents with true risks (e.g. use of synthetic biology to create an organism to increase biofuel production include a gain of function but this activity does not fall under high risk research).
• Introduce and expand exemption with examples, registration-only, and/or notification pathways for low-risk activities.
• Allow abbreviated continuation reviews for stable, previously approved protocols (i.e. umbrella projects). E.g. allow reliance on existing federal oversight mechanisms where equivalent reviews have already occurred.

Without additional calibration to perceived risks, the proposed draft policy will shift biosafety resources toward administrative processing of routine work while reducing institutional capacity to focus on emerging technologies, high-containment research, and incident prevention.

3. Continued utility of Risk Groups: Risk Groups (RG) provide a very useful and widely understood baseline framework for biological-agent hazard identification. However, Risk Groups alone are insufficient for evaluating the full spectrum of risks associated with modern biotechnology and should not be used as the sole determinant of oversight requirements. Risk assessments should continue to incorporate: Agent pathogenicity, Genetic modifications, Route of exposure, Experimental design, Host range, Scale and concentration, Environmental considerations, Available countermeasures, Containment and operational practices.

Recommendations:
Maintain RGs as an initial reference point and emphasize comprehensive project-specific risk assessment.
NIH should provide additional guidance on how RGs interact with Biosafety Levels, genetically modified agents, synthetic biology platforms, gene-drive technologies, and emerging technologies that do not fit neatly into traditional agent-based classifications. This is critical given the increased interest in synthetic biology and use of AI into research designs.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH's goal of fostering broader adoption of biosafety best practices beyond institutions formally subject to the policy is appreciated. However, voluntary compliance is unlikely to increase if the final policy is perceived as excessively burdensome, highly prescriptive, or punitive (which frankly is how it is read and perceived). The following aspects/requirements will definitely discourage participation:
1. Extensive public disclosure requirements.
2. Significant documentation and reporting obligations.
3. Administrative costs associated with implementation (NOTE: all institutions have finite funding, receive limited indirect costs with their grants, and thus EHS has limited staff, who are already overworked).

4. Potential reputational consequences arising from public incident reporting (Practical scenario – no graduate student or postdoctoral fellow or PI will willingly come forward for any type of incident reporting if they knew that NIH plans to post or rather splatter their names on public website. This can be perceived as a public shaming exercise in the name of transparency.

NIH must make sure that institutions adopting this approach voluntarily are not expected to implement the full administrative infrastructure required of large NIH-funded research organizations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: NIH's effort to improve lesson-sharing and incident-learning across the research enterprise is very commendable. However, the current public reporting and transparency provisions create substantial concerns related to security, confidentiality, intellectual property, and reporting culture.
The draft requires public posting of:
• IBC meeting minutes.
• Incident reports.
• IBC rosters.
• Training summaries.
• Related biosafety program information.

While transparency is important, broad public disclosure creates risks including but not limited to National Security and Biosecurity Risks. Publicly available incident reports, meeting discussions, facility information, and governance documentation will lead to aggregation of information about:
• High-containment capabilities.
• Research focus areas.
• Operational vulnerabilities.
• Security controls.
• Incident response procedures.
Do you see countries like China, Iran, North Korea, and Russia provide this level of granularity of information openly? These countries are using our/United States'publicly available information against us and NIH's transparency approach is feeding right into it.

Intellectual Property and Proprietary Research Risks: IBC discussions frequently involve unpublished research concepts, novel methodologies, sponsor-confidential projects, patent-sensitive information, and emerging technologies. Publicly accessible meeting minutes definitely will expose high-value scientific concepts before intellectual property protections are secured.

Reporting Culture Risks: Extensive public disclosure requirements WILL discourage reporting of near misses, procedural deviations, and low-consequence incidents due to concerns regarding reputation, public misunderstanding, and institutional liability.

Recommendation for reporting:
• Create a centralized national de-identified incident-learning/reporting system.
• Release aggregate lessons learned/concepts rather than institution-specific details.
• DO NOT request any proprietary, export-controlled, classified, client-sensitive, and security-sensitive information from institutions

• Establish NIH (internal) standardized redaction criteria before publishing anything.
• Request minutes for public that highlight oversight actions and outcomes rather than scientific or operational details.

6. Other feedback relevant to this resource: Successful implementation of proposed NIH draft policy will require significantly more guidance than what is currently described in the draft policy. NIH appropriately recognizes that supplemental implementation resources will be needed, but no suggestions are provided as to how to achieve this without additional resources or funding.

NIH must consider and provide guidance on
Scope Determination
• Definitions of covered research.
• Exemptions and exclusions.
• Research versus operational laboratory activities.
• Treatment of assay validation, diagnostics, and service laboratories.
Risk Assessment
• Relationship among Risk Groups, Biosafety Levels, and project-specific risk assessment.
• Guidance for synthetic biology and emerging technologies.
• Criteria for containment determinations and containment reductions.
Transparency and Public Disclosure
• Uniform redaction standards.
• Protection of intellectual property.
• Protection of sponsor-confidential information.
• Protection of security-sensitive information.
• Criteria for public versus confidential records.
Administrative Implementation
• Model Biosafety Assurance documents.
• Standardized protocol forms.
• Renewal and amendment workflows.
• Responsibilities of delegated reviewers.
• Expectations for external or centralized IBCs.

Most importantly, Resource and Workforce Needs:
The proposed policy significantly increases institutional responsibilities including oversight, reporting, record-keeping, training documentation, public posting, and compliance monitoring. NIH must conduct a formal assessment or a dry run of implementation costs and staffing impacts and consider phased implementation and must provide additional funding support. Without additional resources, the policy risks becoming an unfunded mandate that disproportionately affects smaller institutions and biosafety programs.

322. Nils Walter

I am responding: On behalf of myself

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): RNA biophysics, molecular biology and genetics

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's goal of modernizing biosafety oversight through a transparent, scientifically grounded, and risk-proportionate framework. However, I am concerned that the proposed definition of "genetic modification" is overbroad as currently written and could inadvertently bring routine, low-risk research activities within the scope of a policy intended to oversee research involving biohazards.

Specifically, the draft defines genetic modification to include the introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of three criteria, including molecules that "can be transcribed or translated." Because these criteria are joined by "or," this language appears to encompass nucleic acids that are transiently introduced into cells and expressed without replication, integration, or any stable alteration of the recipient genome.

This interpretation would potentially classify routine transient transfection with non-replicating plasmids, the introduction of exogenous messenger RNA (mRNA) for transient protein expression, and research involving non-replicating nucleic acid-based vaccine technologies as genetic modification. Such activities are fundamental to contemporary molecular biology, RNA biology, cell biology, biotechnology, and vaccine research. Transient expression of a protein does not, by itself, constitute a stable genetic modification of the recipient cell, nor does it necessarily introduce a biohazard.

The distinction is scientifically consequential. Nucleic acids differ substantially in their capacity for replication, integration, persistence, and alteration of cellular or organismal properties. Their potential risks depend on their sequence and biological function, the properties of the delivery system, the recipient cell or organism, the duration and consequences of expression, and the experimental manipulations involved. The ability of a nucleic acid to be transcribed or translated, considered in isolation, is not an adequate indicator of biohazard potential.

The proposed definition could therefore create unnecessary uncertainty for investigators, institutional biosafety committees (IBCs), and research administrators. Even if many such activities ultimately qualify

for streamlined review, as contemplated elsewhere in the draft policy, ambiguity about whether routine experiments constitute genetic modification could increase administrative burden, produce inconsistent institutional interpretations, and divert biosafety resources from research presenting more substantive risks.

There are also broader implications for public communication and trust. Conflating transient expression of exogenous RNA with genetic modification may reinforce misconceptions about the nature of RNA research and recombinant vaccine technologies. Clear, scientifically accurate terminology is particularly important in areas of research that have direct implications for public health. Biosafety policies should distinguish genuine biological hazards from molecular techniques that are widely used and can be conducted safely under appropriately calibrated laboratory practices.

I recommend that NIH clarify and revise the definition before finalizing the policy. In particular, the definition should distinguish among:

1. Stable genetic modification, involving heritable or persistent genomic alterations, including integration and genome editing;
2. Replication-competent nucleic acid systems, including constructs capable of one or more cycles of replication in the relevant host cell or organism; and
3. Transient nucleic acid expression, involving non-replicating, non-integrating nucleic acids that may be transcribed or translated but do not themselves produce a stable genomic alteration.

The third category should not automatically constitute genetic modification for purposes of this policy solely because the introduced nucleic acid can be transcribed or translated. Instead, such research should be subject to oversight proportionate to its actual biological properties and experimentally defined risks. Appropriate oversight would, of course, remain warranted when the introduced material, encoded product, delivery vehicle, or experimental procedure presents a relevant biological hazard.

NIH should also clarify the intended relationship between this definition and the draft policy's provisions for delegated IBC review of plasmids and replication-incompetent, non-integrating viral vectors expressing reporter genes or low-risk transgenes. Explicitly addressing transiently introduced mRNA and other non-replicating expression systems would help ensure consistent implementation across institutions and experimental platforms.

A corrected phrase could, e.g., simply combine the two statements:
- Have the potential for one or more cycles of replication in a cell; or
- Can be transcribed or translated
into:
- Have the potential for one or more cycles of replication in a cell and can be transcribed or translated

Finally, I encourage NIH to further evaluate the operational implications of the proposed definition with experts in molecular biology, RNA biology, gene delivery, vaccine development, and institutional biosafety. The objective should be a definition that is mechanistically precise, readily interpretable, and proportionate to risk.

A modern biosafety policy should provide robust oversight of genuinely hazardous biological research while avoiding unnecessary regulatory ambiguity for routine, low-risk research. Revising this definition would advance both objectives, preserve institutional resources for higher-risk activities, and support public confidence in biomedical research and its applications.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support a tiered oversight framework that assigns review and approval responsibilities according to the potential biological risk of the research. Federal review should be reserved for activities presenting substantial risk, significant uncertainty, or implications extending beyond the local institution. For well-characterized, lower-risk research, appropriately trained institutional biosafety committees (IBCs), with delegated review where warranted, are better positioned to make timely, context-specific decisions.

The policy should clearly define the criteria that trigger federal review and provide mechanisms for consistent interpretation across institutions. NIH review should have transparent timelines and a process for resolving disagreements or obtaining timely clarification. The framework should also recognize that biological risk depends on the properties of the agent, the specific genetic modification, the experimental procedure, and the containment environment—not simply on the presence of recombinant nucleic acids. This approach would strengthen accountability while avoiding unnecessary duplication, delays, and administrative burdens for low-risk research.

3. Continued utility of Risk Groups: Risk Groups remain a useful starting point for characterizing the inherent hazards of biological agents, but they should not be used as a substitute for activity-specific risk assessment. Conversely, Biosafety Levels, as described in the Biosafety in Microbiological and Biomedical Laboratories (BMBL), define combinations of containment practices, equipment, and facility requirements; they are not themselves measures of an agent's inherent hazard.

I recommend retaining RG classifications as a baseline while explicitly distinguishing them from the risk assessment needed to determine appropriate BSLs for particular experimental activities. Genetic modification does not invariably increase biological risk, and some modifications may attenuate an agent or render it replication-incompetent. Other modifications may introduce new hazards that warrant additional precautions. NIH should therefore provide clear criteria for evaluating the effects of specific modifications, including relevant evidence of attenuation, replication competence, host range, and biological activity. A transparent, evidence-based process should permit justified adjustments to containment while maintaining appropriate safeguards for genuinely higher-risk research.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I support encouraging voluntary adoption of sound biosafety practices at institutions and in research settings not formally subject to the policy. Effective voluntary compliance is most likely when NIH provides practical guidance, accessible training, model procedures, and proportionate risk-assessment tools that can be adopted without requiring institutions to reproduce the full administrative infrastructure of NIH-funded research programs.

NIH should distinguish clearly between recommended best practices and mandatory requirements, and should avoid creating the impression that non-NIH-funded research is subject to identical obligations when it is not. Outreach through professional societies, biosafety organizations, universities, and other

research networks could promote consistent practices across the broader scientific community. A confidential, nonpunitive mechanism for seeking advice and reporting near-misses would further encourage transparency and learning. Voluntary participation should be designed to build trust and strengthen safety culture rather than inadvertently discourage investigators from sharing information or conducting beneficial research.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed templates could improve consistency, transparency, and institutional learning, but they should be concise, practical, and proportionate to the nature and severity of the event or activity being documented.

For incident reporting, I recommend distinguishing events that pose a credible risk of exposure, infection, or release from minor procedural deviations and near-misses that are appropriately managed locally. The templates should capture the nature and potential consequences of the event, immediate corrective actions, contributing factors, and preventive measures without requiring redundant narrative or information unrelated to risk assessment. Clear definitions of reportable events, reporting timelines, and expectations for follow-up would help institutions apply the requirements consistently.

For meeting minutes, the template should document the substance of the IBC's risk assessment, the rationale for its decision, the required containment and mitigation measures, and any conditions imposed. It should not require unnecessarily detailed reproduction of the protocol or sensitive operational information that does not contribute to meaningful oversight.

Because the draft contemplates public posting of incident reports and meeting minutes, NIH should provide explicit guidance on protecting personally identifiable information, employee and student privacy, confidential medical information, proprietary research, and sensitive security-related details. Standardized redaction procedures and clear criteria for determining what information must be disclosed would help reconcile transparency with privacy, security, and responsible research conduct. NIH should also consider whether the same reporting requirements and level of detail are appropriate for institutions of very different sizes and administrative capacities.

6. Other feedback relevant to this resource: Successful implementation will require clear, accessible guidance that translates the policy's principles into consistent decisions in real laboratory settings. I encourage NIH to develop practical examples and decision trees addressing common research activities, including transient plasmid transfection, exogenous mRNA expression, non-replicating and non-integrating viral vectors, genome editing, recombinant vaccine technologies, and work involving attenuated or replication-incompetent agents. These examples should illustrate how the scope of the policy is determined and how the appropriate level of oversight follows from a documented, activity-specific risk assessment.

Additional guidance would be particularly valuable on the distinction between genetic modification and transient nucleic acid expression; the relationship between RG classification and BSL selection; the criteria for delegated IBC review versus full committee or federal review; and the evidence required to justify changes in containment. Model procedures, standardized terminology, frequently asked questions, and training materials for investigators, IBC members, and biosafety professionals would

promote consistent implementation.

NIH should also provide a reasonable transition period, opportunities for institutions to seek authoritative clarification, and a mechanism for updating guidance as scientific methods evolve. Consultation with researchers across disciplines, institutional biosafety professionals, and institutions with differing levels of administrative resources will be essential. These implementation resources should support a risk-based policy that is scientifically rigorous, predictable, and feasible, while minimizing unnecessary burdens on routine biomedical research.

I support the overall goal of streamlining, simplifying or removing regulations wherever safely possible.

323. Iris Lindberg

I am responding: On behalf of myself

Name: Iris Lindberg

Name of Organization: University of Maryland Baltimore

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/17/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): neurogenerative disease; neuroscience

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope is too wide. The added requrirement for a new IBC application every 3 years adds a significant regulatory burden (I have used the same viruses for 8 years now and it is much easier to simply renew). I strongly recommend permitting renewals.

I also do not think we need to provide additional details on commonly used research viruses, ie AAV2s and lentiviruses. We have been using these reagents for a decade to generate amazing results. There is no emergent biohazard. Section V-C will be especially difficult for IBC offficers to address. (and the idea that a component of a new virus will function as it did in the original virus is incorrect. Current versions of lentiviruses contain parts of other viruses that are *intentionally incapacitated* when reconstituted into the new viral reagent.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Federal oversight should address only REAL risks to human health, ie risk organisms that require handling procedures stonger than Biosafety Level 2 (ie biosafety cabinets). More oversight of BSL2 work will only add a significant regulatory burden for both universities and researchers. Even our own IBC people are telling us this.

3. Continued utility of Risk Groups: The Biosafety Levels outlined in the CDC documents are working well. No need to revise.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Disseminate information on safe handling and current information on KNOWN "likely risky" constructs (ie NOW we know that addition of a furin site specifically to coronaviruses is bad!).

But it is almost certain that all PIs constructing viruses are already aware of this specific construct; and the idea that the federal government could ever assess these risky constructs ahead of time to block their construction is simply not a reasonable assumption.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: none

6. Other feedback relevant to this resource: The current guidelines are adequate. Let's be honest here: if researchers really wanted to make a malignant virus, which they categorically do NOT, they would not report its construction to the IBC ahead of time so that it could be denied via regulation!
And the idea that a local IBC could "catch" the construction of a pathogen ahead of time is simply not feasible.

Adding more regulatation does nothing to keep us safer.

Uploaded File: 2026-10-17-Biosafety-Policy-COmment.docx

Description: Comment on the proposed changes, primarily focused on the need for continued class-wide approvals for some types of research that are determined to be safe

I appreciate the chance to provide input on the new draft NIH Biosafety Policy.

My lab studies how cells get their specific identity during development to empower regenerative therapies that aim to replace particular kinds of cells. We are particularly focused on understanding how the proportion of different intestinal cells is regulated, since this is disrupted in most kinds of intestinal disease. To visualize different types of intestinal cells, we regularly make new transgenic lines that cause that type of cell to glow under a microscope by expressing fluorescent proteins. These plasmids are constructed in standard lab E. coli strains that are non-pathogenic, and neither the plasmid nor the resulting fish line have any components that could affect human health. In fact, fish that have been similarly engineered to express such fluorescent proteins are readily available in pet scores as "Glofish" and pose no risk. To test the role of different genes in regulating the development of different intestinal cell types, we regularly use CRISPR/Cas9 with synthetic guide RNAs to create fish lines where particular genes are disrupted, in order to study their effect. Similarly, this approach poses no risk to the public, since there are no transmissible elements here.

Under the current biosafety protocol, these activities were reviewed in a 'blanket' fashion and judged to pose no risk, and so minor variations do not require re-review. For instance, creating a transgenic fish line that fluorescently labels a cell type was determined to pose no risk, and so I currently do not need to have each individual line we create pre-reviewed when a different color protein is expressed or it is moved into a different cell type. We do not use dual-use reagents or viruses, any components that could be expected to cause human disease, and none of the work that we do with recombinant DNA could be transmissible or affect human health.

Our lab creates up to 100 new plasmids per year, including the intermediates during the process of constructing them as well as a similar number of guide RNAs for CRISPR experiments. Obtaining specific advance approval for each construct or guide RNA would likely take 30 minutes or longer, given the time required to assemble the application, submit it through an online system, and verify the results. This would introduce 100 hours per year of extra administrative burden that could not be handled by administrative assistants, given the technical nature of the documentation, which would be multiple weeks of researcher time taken away from scientific work. This would be approximately $8,000 per year of salary spent on this administrative work.

I agree that stringent oversight is critical for research that has potential biosecurity implications, dual-use implications, or works with potentially transmissible or pathogenic materials. However, for work like ours, this administrative burden will provide no additional safety, since none of the above apply to us, as has been determined by Biosafety

Committee review of our research program. I would be extremely grateful if the NIH preserved exemptions for low-risk activities, where more blanket approvals for categories of safe activities can be granted after stringent biosafety committee review of a laboratory's program. I think this would be in the taxpayer's interest to make sure that the money they spent on science goes toward critical research to help improve human health, rather than potentially ineffective administrative work.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: transient expression does not equal gene modification . Transient aaaaaaexpression allows us to rapidly test gene function and protein localization without the time-consuming process of generating stable transgenic lines. This speed is essential for validating constructs and confirming experimental results before committing to longer-term studies.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I do not think federal oversight is required.

3. Continued utility of Risk Groups: Transient expression is not modification. Guidlines are useful but perhaps not useful in this case.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Useful

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Materials were not available to me

6. Other feedback relevant to this resource: I don’t believe that NIH should spend any of it’s resources on regulation of this area of research.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Gold Standard Science

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support effective biosafety oversight, but I am concerned that the proposed definition of "genetic modification" is scientifically broad. Biosafety policy should use precise biological terminology and establish requirements proportionate to demonstrated risk.

Section II includes the introduction of nucleic acids that can be transcribed or translated, without requiring a stable alteration of the recipient's genome. This conflates distinct biological processes: transient gene expression, infection, and lasting genetic modification.

A common respiratory viral infection illustrates the problem. Viral nucleic acids enter host cells and undergo replication and expression, but describing a person with a cold as "genetically modified" would be misleading. I recognize that this policy concerns laboratory research rather than ordinary community infections. Nevertheless, a definition that invites this interpretation needs revision.

NIH should distinguish stable genomic alteration, transient delivery and expression of nucleic acids, and infection with an unmodified biological agent. Each may warrant biosafety assessment in a research setting, but they should not be treated as interchangeable concepts. Oversight of an infection experiment can be justified by the properties of the pathogen and the procedures involved; it does not require redefining infection as genetic modification.

I am also concerned about the public consequences of this terminology. An authoritative federal policy should improve understanding of genetics, biotechnology, and infectious disease. Language that blurs these distinctions could instead reinforce misconceptions and politicize subjects that require careful scientific explanation.

I urge NIH to revise this definition before finalizing the policy, clearly identify the hazards each category is

intended to address, and explain the evidence supporting the proposed scope. Genetic modification should not itself be used as a substitute for identifying a credible mechanism of harm.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Oversight should be calibrated to the actual hazards of an experiment, including pathogenicity, transmissibility, toxicity, exposure routes, scale, and available containment measures. The presence of introduced nucleic acids alone is not a sufficient measure of risk.

NIH should provide explicit exemptions or streamlined institutional determinations for well-characterized activities presenting negligible biosafety risk. Delegating review can reduce committee workload, but it does not eliminate the burden of preparing, processing, and maintaining approvals.

Before expanding mandatory oversight, NIH should explain what safety gap each additional requirement addresses and assess its likely benefits against its administrative costs. Unnecessary review can consume the same investigator and biosafety personnel time needed to evaluate consequential hazards.

The final policy should strengthen the capacity to recognize and manage meaningful risks while preserving efficient conduct of low-risk research. Scientific evidence and proportionate safeguards should determine the requirements.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

329. Kate Keller

I am responding: On behalf of myself

Name: Kate Keller

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): vision research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of work regarding use of human primary cells is not well defined. I have been working with primary human cells for 20+ years. They are critical to my work on deciphering how glaucomatous cells are different from healthy cells.
We get eye tissues from the eyebank, who have their own set of rules that they adhere to about who's eyes can be donated for transplant and research. These are well-defined and follow strict regulation at the Federal level. Moreover, we also exclude eyes from donors with certain conditions e.g. sepsis, that could pose risk to personnel in our labs.
If we have to start screening for adventitious agents the financial cost and time spent screening each of our cells would cripple much needed research in my lab. The proposed changes don't even define which agents I am meant to screen for.
I realize that the importance of preventing spread of disease and the health of our research workers, but this policy does little above what we already do to keep them safe. It just causes unnecessary burden for scientific research. NIH is pushing the use of NAMs to reduce animal work and these proposed changes make it more difficult to make this change.
Importantly, NIH needs to define "adventitious agent"

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed changes seem to over-burden folks at the local level, with no help from the Federal level to alleviate the increased administrative and financial burdens that come with these proposed changes.

3. Continued utility of Risk Groups: As I already mentioned above, NIH needs to define "adventitious agent". If we do not know what we need to screen for, then we're uncompliant. There is research already being done using viruses to deliver gene therapies to the eye (e.g. FDA-approved Luxturna), which are helping humans see again. Not all genetically modified agents are bad. There needs to be careful consideration about those modifications that can help, from those that cause harm. Again, the definitions and guidance from the NIH are critical in determining this at a local level.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It's very unclear how you will separate minor events from those that are of real concern. There needs to be much more thought and guidance into how researchers should document incidents that support accountability without compromising research security or mischaracterizing minor indicents.

6. Other feedback relevant to this resource: If these guidelines are adopted, it is going to take much longer than 6 months to implement at the local level. Institutional policies will need to be updated, personnel will need to be trained, IBC will need to be expanded with knowledgeable personnel, etc, etc. Again, this is placing undue burden at the local level without support from the Federal level. NIH / DDS will need to publish practical implementation tools before any implementation can be done at the local level. This all takes time and I do not see how this can be done in the proposed 6 month timeline.

Description: Comments regarding NIH Biosafety Policy Draft

Priority requests to NIH OSP Regarding Biosafety Policy Draft

- **<u>Certify Instutional Biosafety Program Compliance with Policy.</u>**

  1. Certification of **compliance** with the new NIH Biosafety Policy, and **confirmation of programmatic structure**, institutional **empowerment of Biosafety Program**, and **leadership position of Biosafety Officer** must become part of the grant application. Similar to animal program section.

- **<u>Define the minimum requirements for an Instutional Biosafety Program.</u>**

  1. Partial quote: '*. . . the National Institutes of Health (NIH) is committed to ensuring that* ***gold-standard science*** *is conducted under* ***gold-standard biosafety conditions****.*"
  A single, egregious oversite is that the requirement for a "Biosafety Officer" defaults to that listed in the current NIH Guidelines. How can an institution empower and run a "**gold-standard biosafety program"** without mandating a program lead that has significant biosafety experience?

  2. Pick a consistent title for the policy that reflects what the NIH wants / needs: Is this a "Biosafety Policy", a "Biosafety & Biosecurity Policy", or a "Policy for work with Biohazards"? Each of the titles will be interpreted differently by institutional leadership.
  This is important because the draft title "***Biosafety Policy for Research Involving Biohazards"*** (Biosafety & Biosecurity Policy?) does not address the fact that biosafety programs include a comprehensive administrative portfolio that includes research safety, compliance, ethics, training, committee review, and approval portfolio.

  3. Define what level of institutional empowerment must be granted to the Biosafety & Biosecurity program. Must both components be supported or is either one, biosafety or biosecurity, adequate to satisfy this policy?
  A biosafety officer or biosafety professional overseeing this gold standard biosafety program must be granted administrative level empowerment equivalent to the "Director of Animal Welfare", Director of Human Research Protections" or the "Institutional Veterinarian". A more appropriate role, to accomplish what the NIH is striving toward, will be Assistant or Associate Vice Provost or Vice President for Biosafety & Biosecurity Programs. Someone at the institutional leadership level, with appropriate biosafety experience, must be empowered to oversee these programs. **This must be mandated by the policy or it won't**

happen. Lack of this empowerment is currently what fails many biosafety programs.

- **Codify the Institutional Biosafety Committee (IBC)**

  1. Define what level of institutional support is adequate to satisfy policy requirements. Must Institutional resources include similar administrative structure for the IBC that is offered to the IRB and/or IACUC? What is the minimum? Office space, administrative support adequate for the number of IBC committees (or sub-committees), Leadership team consisting of Director, Associate Director, Professional staff separate from the biosafety program? For example, the Director of the IBC office has a separate role from Institutional Biosafety Officer, etc.? The Biosafety Officer sits as a voting member only?

- **Fully Embrace Risk-Based Biosafety**

  1. It is stated that this policy intends to encourage and embrace risk-based oversight and reporting. Yet, the only risk criteria incorporated into this first draft are Biological Agent Risk Groups and Biosafety Levels. These criteria are not applicable to all life science research activities or agents proposed for enhanced biosafety oversight. For example, biologics used in clinical trials cannot be defined by a biological agent Risk Group. Biologics are typically risk assessed by Risk Banding. Include/acknowledge this aspect of risk assessment in the updated draft. Alternatively, allow the biosafety professionals overseeing biosafety programs the freedom to perform risk assessment without specifying the risk criteria that must be used, because in biosafety and especially because of rapidly developing life sciences research programs, "it depends". Please let life science research professionals do what they do best, without restriction.

- **Risk-Based Biosafety**

  1. Since Biosafety Oversight mandated by the New NIH Biosafety Policy is supposed to be risk-based, registration, IBC review, and reporting of Biosafety Level 1 (BSL-1) or biologics band 1, materials and research, is a **NO GO**. Please exempt these low-risk materials from the Policy.

Uploaded File: 3-NIH-Biosafety-Policy-Comments-1.docx

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public confidence in NIH-supported science. I offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

Topic to Address*: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any

resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.

3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory

rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:
    a. the nature and stability of the genomic modification;
    b. whether the modification is heritable and the potential for transmission through breeding;
    c. effects on animal health, phenotype, host range, susceptibility, or disease;
    d. potential entry into breeding or food-production systems;
    e. potential environmental release or interaction with non-research animal populations;
    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and
    g. applicable federal, state, or other regulatory oversight.
2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.
3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.
4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

  deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the

Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

b. State explicitly that the Policy does not address non-biological hazards.

c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

  Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

  the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate, and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

  Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and

Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

I believe the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, I request that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, I welcome the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. I do not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. I recommend that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice

- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, I recommend a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with my earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*
- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. I recommend that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior

leadership;

2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply

another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.
NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, I kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. I encourage NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE

BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The

Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While I support appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes
6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions

throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as “any incident,” “loss of containment,” “significant problems,” and “minor spills... generally do not need to be reported,” and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report “potential releases involving facility and/or equipment failures even when redundant systems were functioning properly” would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure

in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: I recommend the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and

occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. I support preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Comment to NOT-OD-26-112

I appreciate NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions.

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk

and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under

the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure,"

“compliance violation,” and “minor spill.” The policy should clarify whether precautionary post exposure prophylactic treatment is considered “agent-specific treatment”. It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

5. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures,

workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

Recommend that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

6. Other feedback relevant to this resource: N/A

Uploaded File: 1-Recommendations-to-the-NIH-OSP-1.docx

I ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

1. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts;

compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

2. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure

implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological

exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

3. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

4. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

5. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

6. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and

explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

7. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions.

Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Description: Commentary provided during Listening Session #1

NIH Hearing Comments (296 words)

Andrew Maksymowych, Biosafety Officer at the University of Pennsylvania.

These opinions are my own and do not necessarily represent the views of my employer

(1) The designation "Biosafety Modernization Initiative" is presumptuous. The Biosafety profession existed before the *NIH Guidelines* and will exist with or without guidance from the NIH.

(2) Science and technology have evolved, and the Biosafety profession has endeavored to keep pace. Programs do not exist exclusively to support the *NIH Guidelines*.

(3) Biosafety professionals are practicing "risk based" biosafety. It is the *NIH Guidelines* that have been stuck in the past. With that perspective this initiative is overdue and welcome.

(4) 21 Century Biosafety is not currently defined, nor will it be in the future, strictly by the NIH Policy. The OSP acknowledged that other Federal agencies may have different expectations for biosafety, independent from the new NIH Policy.

Step one, must be to define programmatic pillars for this policy:

(5) **Harmonization:** Will new NIH Policy be harmonized with international biosafety standards?

(6) **NIH Policy:** Must not confound the practice of biosafety.

(7) **Institutional Biosafety Committees:** Have evolved to address biosafety risk assessments beyond narrowly addressing NIH guidance. Are there expectations for significant operational changes?

Will the NIH detail expectations regarding IBC status within institutional compliance committee hierarchy, mandating institutional support and provision of adequate resources?

(8) **The Biosafety Profession:** Empowerment for Biosafety Programs from the NIH is welcome. What this may look like remains to be defined and must be coordinated by biosafety professionals.

(9) **Finally:** "Because we are dealing with the federal government" only Leadership is empowered to pursue such interactions. Guard against persistent tendencies for policy activities such as this to be appropriated by leadership. Consider preferentially, input from biosafety profession "boots on the ground".

Thank you!

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed NIH biohazards-policy language is harmful because it expands "genetic modification" far beyond its conventional meaning. Genetic modification generally implies a stable or permanent alteration to an organism's genetic material. Under the proposed definition, however, any introduced nucleic acid that "can be transcribed or translated" could qualify—even when it does not integrate into the genome or create a lasting genetic change.
This would sweep routine and often transient research tools into the same category as genome-altering technologies. Examples could include transfected plasmids, exogenous messenger RNA (mRNA), and several recombinant vaccine platforms. Treating these fundamentally different technologies as equivalent would:

1) Create scientific and regulatory confusion by blurring the distinction between transient gene expression and stable genomic alteration.
2) Impose unnecessary oversight and administrative burdens on common research methods that do not permanently modify genomes.
3) Produce inconsistent interpretations and compliance decisions across institutions and Institutional Biosafety Committees.
4) Mislead the public into believing that routine RNA research or certain vaccines permanently alter a person's DNA.
5) Undermine trust in biomedical research and vaccination, reinforcing existing misinformation about mRNA and recombinant vaccine technologies.
6) Delay research and public-health responses by subjecting well-established, comparatively low-risk methods to requirements designed for genuinely genome-altering work.

A scientifically sound policy should distinguish among temporary expression, replication-capable nucleic acids, and stable genomic changes, with oversight proportional to each technology's actual biological risk. Without those distinctions, the proposed definition could hinder research while producing little

corresponding biosafety benefit—and could have serious downstream consequences for vaccine confidence and public health.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: This change in language absolutely should not be adopted, it has the potential to would bring to a staggering halt all fundamental RNA and DNA research in the U.S.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Thank you for the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. I support NIH's efforts to strengthen biosafety oversight and recognize that transient nucleic acid expression can pose significant risks that require careful review.

My concern is that the proposed definition of "genetic modification" groups permanent changes to the genome together with transient expression. Both warrant oversight, but they present distinct safety considerations that should remain explicit in the policy.

Permanent genomic modification raises concerns about unintended genetic changes and their persistence in cells and their descendants. Transient expression using mRNA, nonintegrating DNA, or self-amplifying RNA raises distinct concerns such as the amount and duration of expression, the cells and tissues affected, immune responses, and the effects of the delivery system and expressed product. These approaches differ from one another and should not be treated as interchangeable.

When transient expression does not alter the genome, it can reduce some risks associated with permanent modification. This does not mean that transient expression is always safer or that its effects are necessarily temporary. For example, transient delivery of gene-editing machinery can still produce permanent genomic changes. The important point is that each approach requires assessment of its specific risks.

Although this policy addresses research biosafety, NIH's terminology may influence how these technologies are understood elsewhere, including by drug regulators. A broad definition without clear distinctions could make it harder to assess and communicate the risks that matter for patient safety.

I encourage NIH to distinguish permanent genomic modification from transient expression, through clear subcategories. This would preserve appropriate oversight while making clear that inclusion under the same policy does not imply the same biological effects, risks, or regulatory needs.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): molecular biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As written, the draft policy is overbroad in its definitions of what needs extra oversight. By including "introduction of nucleic acids that:
can be transcribed or translated,
can replicate,
can cause stable genomic alterations,
and also includes genomic changes introduced through passaging, reassortment, chemical mutagenesis, or radiological means," it captures much of the basic biology research that is very common and safe in research labs. We have 50+ years of data demonstrating the safety of introducing engineered vectors into cells to understand both normal biology and disease processes. I suggest being more specific to focus on the intended target which is presumably generating anything that would harm humans rather than everything that happens in a molecular biology, biochemistry, genetic, pharmacology, cell biology, etc. research setting

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

RE: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Reviewing Officials:

Duke University appreciates the opportunity to provide comments on the draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112). Duke is a private research university with a major academic medical center and one of the nation's largest academic research enterprises. As a member of COGR, Duke would like to note that we endorse the letter submitted by that organization.

Subject matter experts in the Biological Safety Division of the Duke Occupational and Environmental Safety Office reviewed the draft policy and compiled the following comments. The concerns outlined below could reduce researcher safety and slow scientific advancement in the United States by introducing unnecessary regulatory burdens and creating fear among scientists. The areas of greatest concern are as follows:

1. **Public Posting of Identifiable Information**
   The draft NIH policy requires public posting of IBC meeting minutes without redacting information such as Principal Investigators' (PIs) names, biological agents, grant numbers and other information. Notably, the requirement to post IBC meeting minutes has been in place since June 2026. When carefully implemented, such measures help the public understand how the IBC deliberates the risks associated with biomedical research and recommends appropriate biocontainment practices. While Duke supports such transparency, we are concerned that the new requirement to publicly post incident reports will have an adverse impact in discourage reporting, therefore creating an unintended safety risk.

   NIH proposes requiring incidents to be reported using a standardized template. Although the template states that personally identifiable information should not be reported, it requires the PI's name, grant number, general location and position titles of involved individuals. Providing the foregoing information could allow individuals to deduce the location where IBC covered work is taking place, as well as the individuals involved. This not only presents public safety risks if individuals with nefarious intent seek to target locations where IBC work is occurring, but also the safety of the individuals involved. A chilling effect on reporting will limit biosafety professionals' ability to assess individual incidents, recommend mitigation measures, monitor trends and develop awareness and training initiatives that reduce injuries and exposures.

These fears are not unfounded. Researchers have faced well-documented threats from activist groups. If NIH proceeds with the proposed incident reporting requirements, it should strongly consider an anonymized, aggregated reporting system, with access to identifiable information restricted to authorized users who have a legitimate need to know and whose access can be tracked.

Additionally, under the current draft, all Select Agent work would require IBC review, be documented using the required template, and be subject to public posting. These changes raise concerns about consistency with the biosecurity measures required under federal select agent regulations to prevent unauthorized access to restricted select agents and toxins. As noted above, PI names and associated location information could link personnel to laboratories. Making this information publicly available is inconsistent with regulatory precedent, which seeks to impose the utmost security parameters around Select Agent projects.

Requiring standardized templates for IBC meeting minutes and incident reports, combined with mandatory public posting, provides information publicly that would be accessed efficiently by adversaries to the U.S through automated tools and sophisticated machine learning capabilities, resulting in a loss of US based and funded intellectual property. These cyberbiosecurity concerns, combined with potential physical security concerns, substantially expand institutions' exposure to attacks and increase the vulnerability of the American scientific enterprise.

2. **Unfunded Administrative Burden**

The draft policy significantly expands IBC responsibilities compared with the current NIH Guidelines and introduces more prescriptive recordkeeping requirements. The scope of biological materials requiring IBC review would expand to include all wild-type organisms, all toxins and all genetically modified cells, viruses and organisms. Previously, this scope was limited to a defined subset of recombinant or synthetic nucleic acids.

Institutions have historically relied on biological safety professionals as subject matter experts to review research, conduct risk assessments and recommend mitigation measures to ensure safe research practices. This expert review has enabled institutions to address biological hazards in the workplace as they arise without delaying research through review by a committee that meets periodically, often monthly. The proposed changes will deflect those limited resources that historically focused on higher- risk research, to review research activities that pose little risk, thus creating delays in the advancement of science.

Additionally, the draft policy limits each registration approval to three years, after which an entirely new registration must be submitted and approved. This would substantially increase the number of registrations requiring full review on a recurring basis without a corresponding benefit since existing mechanisms at many institutions encourage updates more frequently than every three years, making mandatory expiration and full resubmission unlikely to provide meaningful additional risk reduction.

3. **Conditional Recordkeeping Requirements**

The recordkeeping requirements tie IBC records, including meeting minutes and incident reports, to individual grants and stages in their lifecycles.

An individual IBC registration may support multiple grants with different end dates and retention requirements, while a single set of meeting minutes may document decisions concerning several registrations. Linking retention requirements to individual grant lifecycles therefore creates uncertainty about which retention period governs these shared records. NIH should establish a clear baseline retention period for IBC records and clarify how institutions should apply longer grant-specific requirements when records cover multiple projects or funding sources.

Duke respectfully urges the NIH incorporate community feedback before finalizing the draft Biosafety Policy for Research Involving Biohazards. Any changes should address concerns related to research safety and impacts to scientific advancement in the U.S.

On behalf of Duke University, I appreciate the opportunity to comment on this proposed policy. I would be most willing to continue discussing matters related to these considerations.

Respectfully submitted,

[redacted]

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I would like to comment on the definition of Genetic Modification. The way the new draft is phrased, it defines not only the stable introduction of a DNA alteration as a genetic modification, but also the transient introduction, e.g., of an mRNA, which meets the criterion of being 'translatable'. I believe this to be factually wrong and misleading, as such an introduction does NOT alter the genome, and an mRNA that is introduced will not be stably present in the cells.
Defining such an introduction as a genetic modification will almost certainly (further) erode the public trust in routine RNA research, as well as in RNA-based treatments and vaccines, with adverse public health outcomes due to reduced funding and reduced public acceptance.
Even as a non-U.S. researcher, not undertaking NIH-funded research, I believe such a change in policy to potentially have consequences also for global research. Therefore, for the benefit of U.S. and global research, I would invite the NIH to refrain from introducing the criterion 'Can be transcribed or translated' as part of the definition of Genetic Modification.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The overall objective of establishing a comprehensive biosafety policy for research involving biohazards is supported. However, the policy should explicitly recognise that institutions outside the United States may already be subject to robust national legislative and regulatory oversight frameworks.

In New Zealand, biological hazards are managed through a combination of statutory and institutional controls, including the Biosecurity Act 1993, Hazardous Substances and New Organisms Act 1996, Health and Safety at Work Act 2015, Environmental Protection Authority approvals, and institutional biosafety governance processes. Similar frameworks exist in many other countries.

The policy should therefore clarify that oversight requirements are intended to complement, rather than duplicate, equivalent national regulatory systems. Foreign institutions should be permitted to demonstrate compliance through existing national oversight arrangements where these achieve equivalent biosafety outcomes.

The proposed scope would create an additional oversight burden for research activities that are not funded by NIH but occur within institutions that receive some NIH funding. Applying NIH biosafety obligations across all institutional research regardless of funding source could extend the policy beyond its intended purpose and create unnecessary duplication where risks are already managed by national regulators.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered and risk-based oversight model is appropriate and supports the efficient allocation of regulatory and institutional resources.

Oversight should be proportionate to the nature and magnitude of risk, with higher-risk activities receiving greater scrutiny and lower-risk activities managed through institutional processes. Local biosafety committees and institutional governance bodies are often best positioned to assess specific research activities, local facilities, workforce capability, and operational controls.

For international institutions, tiered oversight should explicitly recognise the role of national regulators and existing legal obligations. Federal NIH requirements should focus on matters directly relevant to NIH-funded research and should not duplicate reviews, approvals, reporting, or containment determinations already required under national regulatory systems.

A key principle should be subsidiarity: oversight should occur at the most appropriate level, with NIH requirements addressing genuine gaps rather than replicating existing controls.

3. Continued utility of Risk Groups: Risk Groups should continue to be used as the starting point for biological risk assessment. Risk Group classification provides an assessment of the inherent hazards associated with an organism and remains a useful foundation for evaluating biological risk.

However, containment requirements should not be determined solely by an organism's Risk Group or through automatic assignment of a Biosafety Level. Effective biosafety management requires a broader risk assessment that considers the specific activities being undertaken, including:
• The nature of the experimental procedures.
• Scale and volume of work.
• Potential exposure pathways.
• Routes of transmission.
• Environmental considerations.
• Competency and training of personnel.
• The impact of any genetic modifications on the organism's risk profile.

This approach is consistent with the principles set out in the WHO Laboratory Biosafety Manual and aligns with the risk assessment framework used in New Zealand containment standards, where risk assessment is the primary determinant of appropriate containment measures. Under these frameworks, Risk Group classification informs the assessment but does not, by itself, prescribe the containment level required for a particular activity.

This distinction becomes particularly important for genetically modified organisms. Genetic modifications may increase, decrease, or otherwise alter risk in ways that cannot be adequately captured through organism classification alone. Consequently, containment decisions should be based on a comprehensive assessment of the modified organism and the proposed work rather than a predetermined linkage between Risk Group and containment level.

An additional consideration for international institutions is the proposed role of the Biosafety and Containment Steering Committee (BCSC) in determining or approving containment requirements. Where the policy contemplates referral of containment decisions to NIH bodies, a framework in which overseas institutions must seek NIH approval for containment determinations that are already subject to established national regulatory and institutional processes should be avoided.
In New Zealand, containment requirements for regulated organisms are determined within a legislated framework that includes Environmental Protection Authority approvals, applicable containment standards, institutional biosafety expertise, and activity-specific risk assessments. Institutional Biosafety Committees and subject matter experts are expected to exercise professional judgement within these

legal requirements. Requiring external approval of containment decisions would create uncertainty regarding regulatory accountability and could conflict with obligations under national legislation.

While consultation, advice, and guidance from NIH may be valuable, the policy should recognise the authority and competence of equivalent institutional and national oversight systems outside the United States. International institutions should retain the ability to determine appropriate containment measures through their own regulatory and governance frameworks, provided these achieve outcomes consistent with the objectives of the NIH policy. The role of NIH committees should therefore be advisory or limited to clearly defined circumstances, rather than becoming a routine approval pathway for containment decisions that are already governed by national regulatory requirements.

A risk-based approach that uses Risk Groups as an initial input, while determining containment requirements through activity-specific assessment, is likely to provide greater scientific rigour, flexibility, and proportionality than an approach that relies primarily on Biosafety Level designation.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH biosafety resources and guidance documents provide valuable reference material that may assist institutions beyond the formal scope of the policy.

However, adoption of these requirements outside NIH-funded research should remain voluntary. Guidance intended for non-NIH-funded research should not become an indirect prerequisite for institutional eligibility to receive NIH funding or participate in NIH-funded collaborations.

Voluntary uptake is most likely where NIH provides:
- Practical guidance documents.
- Model policies and templates.
- Training materials.
- Case studies and examples of good practice.
- Flexible implementation approaches that can be adapted to local regulatory environments.

Institutions should retain discretion to adopt NIH guidance where it adds value and aligns with national regulatory frameworks.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The development of standardised incident reporting and meeting documentation templates has the potential to improve consistency, transparency, and institutional learning across the research sector. Standardisation can support clearer communication of biosafety issues and facilitate oversight where required.

However, the implementation framework should allow sufficient flexibility to accommodate differing governance models across institutions, particularly large and complex organisations.

Many institutions now manage incident reporting and investigation through central Health and Safety functions rather than through Biosafety Committees alone. This approach should not be interpreted as a weakness in biosafety governance or a failure of institutional oversight. In many cases it is an operational necessity driven by organisational size, the volume of incidents and near misses managed across

multiple hazard domains, and the need to maintain efficient, professional investigation and corrective action processes.

Under these models, Biosafety Committees often retain responsibility for policy, oversight, specialist advice, and review of significant biosafety matters, while day-to-day incident management, investigation, corrective actions, trend analysis, and organisational reporting are undertaken through established Health and Safety systems. This integrated approach can improve consistency and ensure that biological hazards are managed alongside other workplace risks within a unified risk management framework.

The policy and associated templates should therefore accommodate equivalent governance arrangements and focus on outcomes rather than prescribing a specific organisational structure. Institutions should have flexibility to demonstrate that appropriate biosafety expertise, oversight, and escalation pathways exist, regardless of whether routine incident management is administered through a Biosafety Committee, a Health and Safety function, or a combination of both.

For international institutions, the reporting framework should also recognise differences in legal and regulatory requirements regarding information collection, disclosure, and retention. Particular consideration should be given to:
• Privacy and data protection obligations.
• Commercially sensitive information.
• Intellectual property considerations.
• Confidential research information.
• National security restrictions.
• Legal obligations imposed by foreign regulators.

The policy should clearly specify:
• The minimum information required for reporting.
• How submitted information will be protected and stored.
• Circumstances in which information may be disclosed.
• Circumstances where foreign institutions may appropriately redact or withhold information.

Where information has already been reported to a competent national authority, NIH should also consider mechanisms that minimise duplicate reporting requirements while ensuring that the objectives of institutional learning and oversight are achieved.

6. Other feedback relevant to this resource: Implementation guidance for international institutions would be particularly beneficial.

Institution-wide application of NIH biosafety requirements will create substantial administrative and resource implications for overseas organisations, including increased biosafety review activities, training requirements, record-keeping obligations, reporting responsibilities, and governance costs. Without careful calibration, these costs will be borne by institutions and funding sources that receive little or no direct NIH support.

To support practical implementation, NIH should consider developing additional guidance that:

• Clarifies how equivalent foreign regulatory systems will be recognised.
• Explains how NIH requirements interact with existing national laws and regulatory approvals.
• Provides examples and case studies relevant to international institutions.
• Identifies circumstances where compliance with national regulatory requirements may satisfy NIH expectations.
• Reduces duplicative reporting where information has already been provided to competent national authorities.
• Clearly defines the extent to which institution-wide obligations apply to non-NIH-funded research conducted within NIH-funded organisations.

Such guidance would improve consistency, reduce uncertainty, and support effective implementation across the international research community.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: It is recommended that NIH maintain the previously established categories of exempt research. NIH describes the purpose of the modernization as expanding oversight to biohazards while "removing red tape for low-risk research" and specifically asks commenters whether the proposed tiered oversight is appropriately calibrated to risk and administrative burden.

Exempt from IBC oversight is not synonymous with exempt from safe laboratory practice. Rather, it represents a determination that the incremental safety benefit of mandatory IBC oversight does not justify the administrative burden for a defined class of low-risk research. Currently exempt research was previously determined by NIH, following notice and opportunity for public comment, not to present a significant risk to health or the environment.

The scope of work with primary and well established cell lines that requires review is unclear. As written, "may be contaminated" could be interpreted to include virtually any primary human or animal cells (including any research involving NHP cells or tissues) for which the infectious-agent status of the source has not been comprehensively established.

NIH should define "adventitious agent," establish a risk-based threshold for determining when contamination is reasonably anticipated, and clarify whether donor screening, testing, source information, or other documentation can establish that primary cells do not fall within this category. The Policy should also clarify its application to commercially obtained cells, repository specimens, patient-derived cells, and primary animal cells and provide examples of included and excluded materials. A merely theoretical possibility of contamination should not independently trigger IBC oversight; the definition should be tied to a known or reasonably anticipated potential hazard to human health. Clear criteria are necessary to avoid additional administrative burden by unnecessarily expanding IBC oversight beyond research presenting a meaningful biosafety risk.

Additionally, The Policy does not provide sufficiently objective criteria for determining when a cell line

qualifies as well-characterized, creating the potential for inconsistent interpretations among investigators, biosafety professionals, and IBCs. NIH should specify what level of information regarding identity, provenance, biological characteristics, and adventitious-agent testing is necessary; whether established commercially available or widely used cell lines may be presumed to satisfy the definition; and how primary, immortalized, genetically modified, and patient-derived cells should be treated. NIH should also provide examples of included and excluded cell lines. Because this determination may affect the scope and level of institutional oversight, a clear, risk-based definition is necessary to ensure consistent implementation and avoid additional administrative burden by unnecessary review of research that does not present a meaningful biosafety risk.

Section IV-2 outlines the only clinical research provision and specifically identifies IBC review for biohazards that shed, replicate, integrate, require higher-risk manipulation, or involve RG2 or higher wild-type agents. There is no discussion of other genetically modified agents being used in clinical research, such as plasmids or RNA, and no discussion of exemptions. Given the https://www.hhs.gov/press-room/hhs-launches-clinical-trials-reform-initiative.html, additional administrative burden should not be introduced by expanding IBC oversight in the clinical research arena.

The Policy should also exempt any covered clinical research studies from mandatory three-year de novo IBC review or permit an administrative continuation process confirming that no material changes affecting biosafety have occurred. Full IBC review should be required only for clinical research presenting local biosafety risk, where there may be questions regarding product handling and possible shedding. This approach would maintain appropriate biosafety oversight while reducing unnecessary regulatory burden.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The incorporation of delegated review has the potential to decrease regulatory burden and expedite review of low-risk research. However, the draft policy is unclear in what may qualify for delegated review. It appears that it is the intent that an initial protocol may qualify for delegated review if it only contains work identified as eligible for delegated review under Section IV-3. Clarified wording is recommended “for minor amendments to previously approved submissions or for initial research protocols”

There are inconsistencies between the descriptions of research that require committee review (Section IV-2) and research that may be eligible for delegated review (Section IV-3). A potential clarification is to state that “Where research is described by both Section IV-2 and Section IV-3, research meeting all applicable criteria specified in Section IV-3 may undergo delegated review unless another characteristic of the research independently requires review under Section IV-1 or IV-2. A delegated reviewer may refer any submission to the full IBC when warranted based on the risk assessment.”

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It is strongly recommended that NIH revise the approach to public posting of incidents so that detailed incident

reports are submitted to NIH but are not routinely required to be posted publicly in their entirety. Alternatively, NIH could provide a template for public posting of standardized, de-identified high level summary information of incidents that might include root-cause categories and corrective actions. NIH could separately require disclosure of additional information when a particular incident presents a compelling public health or safety interest.

This approach balances transparency objectives with the equally important need to preserve a just, non-punitive reporting culture in which researchers and staff are encouraged to report incidents, near misses, and potential safety concerns promptly and completely. It also provides protections for researchers that are increasingly threatened or harassed due to the tools or subject matter of their research.

Importantly, NIH would receive the information necessary to evaluate significant incidents, institutional responses, and compliance. The distinction would therefore be between information necessary for regulatory oversight and information necessary for public transparency, rather than assuming that the same level of detail is needed for both purposes.

6. Other feedback relevant to this resource: The timeline for institutional implementation and compliance with the revised policy should be at least a year after the publishing of the final rule instead of 6 months.

A six-month implementation period is insufficient given the breadth, complexity, and institutional impact. Revising electronic systems to accommodate the new regulations is a significant challenge that will likely prevent many institutions' ability to meet this timeline. Additionally, updating policies and procedures and ensuring that researchers have the training they need to understand the new requirements, including newly covered areas of research, will require additional time. The time required to identify newly covered research is one reason why it is critical for entities to be held to realistic and achievable implementation timelines.

NIH should provide a detailed description of the required elements of an institutional assurance and publish accompanying implementation guidance before policy adoption, including model assurance language, implementation templates, and sufficient lead time for institutions to develop. Administrative burden should be kept in mind in considering required elements.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Molecular and behavioral neuroscience

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: My laboratory uses hundreds of distinct adeno-associated viral (AAV) vectors to study how genes in specific brain cell types contribute to addiction and depression. These are engineered tools — they cannot replicate, they do not cause disease, and they are classified at the lowest biosafety level (BSL-1) by our institution. Every one of them has already been reviewed and approved by our Institutional Biosafety Committee (IBC). The draft policy would upend that entire body of approved work without providing any guidance on what happens next.

The draft says nothing about what happens to research that is already approved. Can we keep working under our current approvals? Do we have to resubmit everything from scratch? Can we amend existing protocols? Without clear answers, institutions will take the safest legal route: stop everything and resubmit. For a lab with hundreds of approved vectors, that could mean months of paperwork before a single experiment can move forward — for tools that pose no meaningful safety risk and have been in use for years.

The draft also lumps all viral vector research into a single broad category without the practical guidance that the current NIH Guidelines provide. The existing guidelines include specific, usable direction for common research tools like AAVs — what containment is required, how to assess risk, what paperwork is needed. The new policy removes all of that without replacing it. Investigators and biosafety committees will be left guessing, and different institutions will interpret the rules differently, creating a patchwork of inconsistent oversight across the country.

One additional gap: the draft provides no direction for laboratories like ours that are beginning to work with human stem cells (iPSCs) in combination with viral vectors. This is an increasingly common research approach, but the draft does not say how it should be classified or reviewed. Guidance on this combination needs to be developed and released before the policy takes effect.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The idea of tiered oversight, matching the level of review to the actual level of risk, is the right approach in principle. The

problem is that the draft does not define the tiers clearly enough to use them. Our AAVs are BSL-1 materials: the lowest risk category that exists. They cannot replicate, they do not cause disease in healthy people, and they have been used safely in research laboratories for decades. Yet under this draft, it is not clear that they would qualify for a lighter-touch review track. Without explicit criteria, our institution will default to full IBC review for everything, adding months of overhead for materials that pose no meaningful hazard.

The three-year renewal requirement is the single most damaging part of this draft for our lab. We have hundreds of approved AAV constructs. Every three years, we would need to resubmit them all — vectors that have not changed, that have been used safely year after year, that our IBC has already reviewed and approved. There is no safety justification for this. It is paperwork for the sake of paperwork, and it will consume enormous amounts of time from both researchers and biosafety staff that could be spent on actual science. NIH should allow institutions to use a "master protocol" approach, where a single protocol covers an entire class of well-characterized vectors, with individual new constructs added through a simple review process. Resubmitting hundreds of unchanged protocols every three years is not a safety measure.

What the draft also does not acknowledge is the real cost of all this compliance work. Tracking renewal deadlines for hundreds of constructs, preparing detailed incident reports within 24 hours, managing the public posting of meeting minutes, meeting new committee composition requirements — none of this happens for free. Most research labs do not have dedicated administrative staff for biosafety compliance. The practical result is that someone in the lab — a postdoc, a lab manager, the PI — will have to do it, taking time away from research. Or the lab will need to hire additional staff, which means spending grant money on administration instead of science. NIH has not estimated what this policy will cost the research community, and it should before moving forward.

The impact will be felt most by those who can least afford it. Junior faculty who are just starting their labs are building their research programs from scratch, generating new AAV constructs, and submitting initial protocols — all while on a tenure clock that stops for nothing. Unclear policy requirements and mandatory renewal cycles will slow them at the worst possible time. Graduate students and postdoctoral researchers are also directly harmed. NIH has invested heavily in fellowship and training programs specifically designed to help trainees complete their work on time. Administrative delays caused by this policy work directly against those investments.

There are also significant downstream complications that the draft does not address. Many research reagents, including plasmids and viral vectors, are obtained under Material Transfer Agreements (MTAs) that were negotiated under specific protocol conditions. When IBC protocols expire, are restructured, or are split across tiers, those MTAs may no longer cover the materials as they are now being used, requiring new rounds of negotiation with the originating institution before research can continue. This a predictable consequence of forcing protocol restructuring on materials whose biological properties have not changed.

One of the strengths of the current IBC system is that it maintains a continuous, evolving record of a laboratory's research within a single protocol. When a lab makes small changes — adding a new

construct, adjusting a payload, refining a method — those changes are tracked as modifications to an existing record. This makes audits, inspections, and reviews far more manageable, because the full history is in one place. The draft's push toward mandatory renewals and tiered restructuring would fragment that history across multiple records and time periods without providing any safety benefit. Biosafety oversight should be designed to make it easier to track what is happening in a lab, not harder.

Finally, IBC approvals do not exist in isolation. They are often directly linked to IACUC protocols and other institutional oversight systems that govern animal research. When an IBC protocol number changes, expires, or is restructured, that change can trigger required amendments across every linked IACUC protocol, even if nothing about the actual research has changed. For a lab with active animal studies and dozens of linked protocols, this could mean a wave of administrative amendments — submitted, reviewed, and approved — for procedures and animal welfare considerations that are completely unchanged. This kind of cascading compliance burden diverts time and institutional attention away from the oversight activities that actually matter.

3. Continued utility of Risk Groups: Risk Groups (RGs) were developed to describe how dangerous a naturally occurring pathogen is to a healthy person. They work reasonably well for that purpose, but they break down when applied to the engineered research tools we use. Our AAVs start from a naturally occurring virus, but that virus has been extensively modified — key genes that allow it to replicate have been removed entirely. What remains cannot reproduce, cannot spread, and cannot cause disease. Our institution classifies these vectors as BSL-1 specifically because of those modifications. But if risk classification starts from the parental virus's RG category, none of that transformation is captured. We would be assessed against the natural virus, not the tool we actually use.

Biosafety Levels (BSLs) are a better fit for this kind of work because they describe what safety practices are actually required in the lab. This is what matters for day-to-day research. Our AAVs are classified BSL-1, meaning they require standard lab practices and no special containment. That classification reflects the actual risk of working with these materials. We strongly recommend that BSL serve as the primary framework for classifying genetically modified research tools, with RG used only as a starting point when the research involves or is closely related to the natural, unmodified version of an agent. If RG is kept as the primary system, the policy must spell out exactly how classifications are adjusted for genetic modification — because right now, different institutions are making those adjustments differently, leading to inconsistent and sometimes arbitrary differences in what is allowed and under what conditions.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Encouraging biosafety practices beyond NIH-funded institutions makes sense. But the draft does not give non-NIH institutions a realistic path to get there. The main obstacle for most of these institutions is not willingness but capacity. Many do not have a full-time biosafety officer, an established safety committee, or staff with experience reviewing viral vector research. Asking them to voluntarily adopt a complex new framework without providing model templates, training resources, or step-by-step guidance is not a strategy that will work. Voluntary compliance provisions need to be paired with real tools that make compliance achievable for smaller or less-resourced institutions.

The draft also misses an important opportunity to reduce unnecessary duplication. Some non-NIH institutions are already operating under rigorous federal safety oversight through the CDC, USDA, FDA, or Department of Defense. They are not operating without safeguards; they are operating under different but comparably strict ones. Rather than requiring these institutions to build a parallel compliance structure just to meet NIH's framework, the policy should formally recognize equivalent oversight programs. Redundant bureaucracy does not improve safety it just creates more work.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting template requires a report within 24 hours for any "serious" incident, but the template never defines what "serious" means for research using BSL-1 viral vectors. A needlestick during an AAV injection is not the same as an exposure to a dangerous pathogen, but the draft treats them as if the same reporting process applies. Without a clear, practical definition — one that accounts for what the actual material is and what real risk it poses — labs and biosafety offices will not know how to apply this requirement consistently. Some will report everything out of caution; others will under-report. Neither is the right outcome. The template needs to include plain-language guidance that helps labs determine whether a given event actually requires a 24-hour report.

The public posting requirement for IBC meeting minutes raises a serious problem that the template does not address at all. IBC minutes describe ongoing research — often in detail, often before that research has been published or patented. Posting five years of unredacted minutes publicly would expose unpublished findings, novel research tools, and investigator-specific information. The template must specify what can and cannot be redacted before posting, and institutions need clear legal authority to make those redactions. Without that, the requirement will either discourage candid discussion in IBC meetings or result in researchers' unpublished work becoming public. The template also needs to allow batch review entries for labs with many similar constructs — requiring a separate detailed entry for each of hundreds of nearly identical AAV vectors would make meeting minutes unmanageably long.

6. Other feedback relevant to this resource: The most direct thing I can say about this draft is that it cannot be put into practice as written. Too many of the questions that labs and biosafety committees need answered are left for "future guidance." However, the six-month implementation clock starts when the policy is finalized, not when the guidance is ready. That means institutions will be expected to comply with a policy they cannot yet fully interpret. The result will be inconsistency, confusion, and for many labs a research pause while they wait for clarity.

There is no set effective date until the supporting guidance is finalized and publicly available. Six months is not enough time to restructure compliance systems when the practical meaning of the policy is still being worked out. The effective date should follow the guidance, not precede it.

AAV-specific guidance should be released on the same day the final policy goes live. The current NIH Guidelines include detailed, practical information about how to handle common research vectors like AAVs — what containment is required, how to assess risk, what a protocol should include. The new policy removes all of that. If it is not replaced before the policy takes effect, labs and biosafety committees will have less usable guidance than they do today. That is not an acceptable outcome. Clear written examples that provide direction for labs with existing IBC approvals will be necessary. Are current approvals still valid? Do we have to resubmit? Can we amend existing protocols? Without explicit

answers to these basic questions, institutions will require full resubmission of everything to be safe. For a lab with hundreds of approved AAV constructs, that is months of work — for research tools that have not changed and pose no new risk.

There is a need for transparency and honesty about what this policy will cost. Keeping up with renewal deadlines, writing 24-hour incident reports, managing public minute posting, and meeting new committee requirements all take real time and real money. Most labs do not have the staff to absorb this. Investigators will either redirect their own time from research to paperwork, or spend grant funding on additional administrative personnel. NIH has not estimated this cost or weighed it against the safety benefits. It should.

The impact on junior faculty and trainees should be addressed. A new faculty member building their lab from scratch, generating their first AAV constructs, and establishing their IBC protocols is in a fundamentally different position than an established lab. They have less staff, less institutional support, less margin for administrative delays and they are on a tenure clock that does not stop. This policy will slow them at the moment when momentum matters most. NIH also funds thousands of graduate students and postdocs through fellowships and training grants built on the assumption that trainees can complete their work on schedule. Paperwork-driven delays undermine that assumption directly. NIH should be required to assess the impact of this policy on trainee timelines and early-career productivity before it is finalized.

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Zoonotic Disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft describes safe, responsible and secure research, but is unclear in title consistency and whether the required program encompasses both biosafety and biosecurity. Please describe the program's full portfolio, including research safety, compliance, responsible conduct & ethical considerations, training, committee review & approval, and security where appropriate. It would be useful to provide an applicability table and consistent definitions for screening.

Our committee has commented widely and such comments need not be detailed again, with few exceptions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The draft requires an IBC, but should explicitly define appointment authority, institutional support, delegation and independent decision-making. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their required workload.

3. Continued utility of Risk Groups: Publish a standardized template distinguishing required, conditional, and optional fields.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): One item that was presented at our discussion, at least briefly, was that only IACUC and institutional IRB members receive stipends for attending meetings. Since Community members spend an equivalent amount of valuable time, travel, etc., it would seem appropriate and fair for them to be likewise compensated.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft links Assurances to public program records and requires public minutes and incident reports. But please consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary and security information.

6. Other feedback relevant to this resource: The proposed IBC Policy and Reporting Requirements are extensive and detailed in some ways and lacking in others. For example, it seems that our Committee repeatedly noted , or via some version thereof, that Institutions need timely, consistent decisions and coordination with related oversight systems.

347. Doni Bloomfield and Tom Inglesby

I am responding: On behalf of myself

Name: Doni Bloomfield and Tom Inglesby

Name of Organization: Fordham Law School and Johns Hopkins University Center for Health Security

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biosecurity, pandemic preparedness, law

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: a. The NIH should provide greater clarity about which experiments will be subject to central NIH review.

The draft Policy requires NIH review for "[r]esearch involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL," with some exceptions.

Unfortunately, the draft's definitions do not provide clear boundaries on which experiments would be subject to NIH review. The draft places in its scope "research involving . . . known or potential risk to human health" and, among other things, wild-type or genetically modified pathogens. The draft nowhere defines what constitutes a "potential risk to human health." The draft defines a novel agent or organism broadly as "[a]n agent or organism not existing in nature, deliberately designed, and possibly derived from multiple, different natural or synthetic sources (e.g., chimeras, or organisms generated by synthetic biology in conjunction with artificial intelligence)."

Under these definitions, many experiments that seem amenable to IBC review may be channeled into NIH review of uncertain duration. For example, consider a proposed experiment to use an RG2 agent, such as an adenovirus, that will be modified to make it less transmissible or otherwise less dangerous, in BSL-2 conditions. Although unlikely, the agent may pose a "potential risk to humans," and it certainly involves a modified pathogen. The resulting virus will likely constitute a "novel agent" because it was deliberately designed and does not exist in nature. It is unclear if the resulting agent has an RG classification or BMBL category because it is no longer an unmodified adenovirus. All of this would suggest that NIH review is called for under the draft Policy before the experiment can begin. At the same time, the specifics of the experimental set-up suggest that IBC review should be sufficient.

The NIH should address this ambiguity by clarifying: experiments involving agents that, in their unmodified form, already have a risk group designation should be classified in that risk group for purposes of the Policy even after modification, unless the experiment is reasonably anticipated to

increase the agent's transmissibility, virulence, or immune evasion.

b. The NIH should include oversight of high-risk animal and plant experimental work in NIH-funded institutions

While the Animal and Plant Health Inspection Service (APHIS), an agency within the U.S. Department of Agriculture (USDA), has primary federal responsibility for overseeing and managing the risks associated with animal and plant pathogen laboratory work, if the NIH is funding work in these fields—or if such work is taking place in NIH-funded institutions—it should provide oversight of this work. Its principal focus on this work should be to assess whether proposed work will increase an animal or plant pathogen's capability for transmission, its potential lethality, and/or its capacity to avoid the immune response of its animal or plant host. The greatest potential risk would be the potential for a novel modified pathogen to cause an epizootic or epiphytotic, or even a panzootic or panphytotic event.

c. The NIH should provide greater oversight of experiments involving genetically modified RG1 agents that pose material risks

Under the current Guidelines, any proposed experiment for introducing drug resistance to an agent in a manner that "could compromise the ability to control disease agents in humans, veterinary medicine, or agriculture" requires NIH Director approval. The draft Policy, by contrast, specifies that all genetic modifications to RG1 agents require only IBC or sub-IBC review. The NIH should clarify that proposals to modify RG1 agents in a manner that is reasonably anticipated to materially increase the agent's transmissibility between humans, its virulence among humans or non-human animals or plants, or its ability to evade the immune system in eukaryotes should be subject to NIH review.

d. The NIH should clarify the definition of "novel agent or organism."

The draft Policy defines a novel agent or organism as "[a]n agent or organism not existing in nature, deliberately designed, and possibly derived from multiple, different natural or synthetic sources (e.g., chimeras, or organisms generated by synthetic biology in conjunction with artificial intelligence)." Because it is impossible to rule out an agent or organism existing in nature, we believe that a novel agent would be better defined as "[a]n agent or organism not known to exist in nature…"

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: a. The NIH Should Reconfigure the Risk Groups to Focus on Epidemic and Pandemic Risk Rather Than Individual Threat

The draft Policy does not say whether it plans to continue using the risk-group classification system included in the current Guidelines. We urge the NIH to revise the risk-group classification system to better focus on epidemic and pandemic risk, specifically by classifying agents that are highly transmissible, and to which most people are immune naïve, at RG3 or RG4. At present, the Guidelines categorize agents based on their "relative pathogenicity for healthy adult humans," rather than their risk to society. To take one example: The Guidelines allow scientists to handle resurrected 1918 influenza, which killed tens of millions of people when it first arose, in BSL-3 enhanced containment. But scientists

studying certain tick-borne viruses, which are deadly but very unlikely to spread between humans, must do so in BSL-4 conditions. Likewise, H2N2 influenza—which killed more than a million people worldwide in a pandemic in 1957–1958—can be studied in BSL-3 enhanced containment. Though the draft Policy does not provide its RG ranking, it appears to contemplate continuing this policy.

The most catastrophic risk of a lab accident or intentional pathogen release is the risk of sparking a major epidemic or a pandemic. A pathogen's virulence is only one factor to be considered in evaluating the appropriate biosafety procedures for its study. The NIH should reconfigure its RG system to consider transmissibility and societal immunity as key factors in RG ranking alongside virulence.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: a. The NIH Should Develop Guidance to Prevent the Creation of Key Mirror-Life Precursors

The creation of mirror bacteria could pose catastrophic risks to humanity and to the environment because such bacteria may be capable of evading most of life's existing defenses. The recent U.S. Government Policy for Stopping High-Risk Life Sciences Research bars the U.S. government from directly supporting the creation of mirror organisms. Yet the draft Policy does not mention mirror organisms or research into mirror biology. To be sure, any research proposing to create a mirror bacterium would presumably require NIH and IBC approval as an experiment involving a "novel agent" without preexisting categorization. But a great deal of the science behind creating mirror life—that is, science that enables others to create a mirror bacterium—might take place without itself creating a full mirror bacterium. Such endeavors may not fall within the draft Policy's definition of research subject to NIH or IBC review. We therefore urge the NIH to develop guidance to ensure that mirror-life precursor research is properly subject to NIH and/or IBC review, without unduly hampering useful research that does not study atypical chirality. The NIH may not be able to develop such guidance in time for the release of this version of this Biosafety Policy, but it should urgently pursue such guidance for subsequent updates, and should publicly signal in the finalized version of this Policy that it plans to urgently create such guidance.

b. The NIH Should Consider Issuing Guidance to Ensure that Biological AI Tools Created at NIH-Funded Institutions are Trained and Released Responsibly

The draft Policy recognizes, albeit with no detail, that agents created with the assistance of biologically trained AI models may pose serious risks. We agree that rapid advances in the capabilities of biological AI models—such as those that can design proteins or even entire viral genomes—are likely to bring both substantial benefits and risks. While the NIH does not have regulatory authority to require risk/benefit assessment and mitigation of all proposed biological AI models, it could precondition funding of biological AI models on such risk assessments. To establish an early test of this process, NIH should require PI-led risk/benefit reviews of proposed biological AI models that are reasonably anticipated to provide instructions, know-how, or blueprints for creating more transmissible, virulent, or immune-evasive organisms capable of infecting eukaryotes. Those reviews should be shared with NIH before funding decisions are made.

We also recommend that the NIH continue to study how it can create oversight mechanisms to require independent review of such AI models once produced, including mechanisms that draw on the policy precedent of the NIH Guidelines and IBCs.

Response to NIH's RFI on the NIH's Draft Biosafety Policy
Submitted by the following authors in their individual capacities

Doni Bloomfield (Fordham University School of Law) and Tom Inglesby (Johns Hopkins University Center for Health Security)

We thank the NIH for the opportunity to comment on its draft Biosafety Policy. We believe that the draft, if implemented, would represent an improvement on the NIH Guidelines for Research Involving Recombinant and Synthetic Nucleic Acid Molecules in several important respects. We also believe that the present draft can be improved along several dimensions. In these comments, we focus specifically on important ambiguities in the draft that may create undue burdens on researchers, areas to improve the clarity of the draft to ensure risky research receives adequate oversight, and arenas for the NIH to develop in follow-on supplements to address future risk from mirror life and AI models trained on biology.

Before we turn to areas for improvement, we wish to highlight several elements of the draft Policy that represent important advancements over the Guidelines.

First, we commend the NIH for moving past the Guidelines' historical focus on experiments involving recombinant or synthetic nucleic acids. As the draft Policy recognizes, wild-type pathogens, as well as pathogens that have been modified through passaging or techniques other than recombinant or synthetic approaches, can also pose substantial risks to society. The draft Policy will likely reduce these risks through improved oversight.

Second, the draft Policy appropriately provides an opening for no-fault, near-miss reporting to the National Biosafety Data and Safety Analysis Center. The NIH must ensure that it lives up to its promise not to punish or penalize reporting individuals or institutions that report near misses. Promoting a culture of reporting close calls, and addressing biosafety and biosecurity issues early, are essential to avoiding consequential lab accidents.

Third, the draft Policy's focus on increased scrutiny for experiments involving novel, emerging, and zoonotic agents is appropriate, especially in light of modern advances in biological AI tools.

We see room for further improvement as the NIH refines the draft. In what follows, we address three of the questions the agency sought comment on.

1. **<u>Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.</u>**

   a. **The NIH should provide greater clarity about which experiments will be subject to central NIH review.**

The draft Policy requires NIH review for "[r]esearch involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL," with some exceptions.[1]

Unfortunately, the draft's definitions do not provide clear boundaries on which experiments would be subject to NIH review. The draft places in its scope "research involving . . . known or potential risk to human health" and, among other things, wild-type or genetically modified pathogens. The draft nowhere defines what constitutes a "potential risk to human health." The draft defines a novel agent or organism broadly as "[a]n agent or organism not existing in nature, deliberately designed, and possibly derived from multiple, different natural or synthetic sources (e.g., chimeras, or organisms generated by synthetic biology in conjunction with artificial intelligence)."[2]

Under these definitions, many experiments that seem amenable to IBC review may be channeled into NIH review of uncertain duration. For example, consider a proposed experiment to use an RG2 agent, such as an adenovirus, that will be modified to make it less transmissible or otherwise less dangerous, in BSL-2 conditions. Although unlikely, the agent may pose a "potential risk to humans," and it certainly involves a modified pathogen. The resulting virus will likely constitute a "novel agent" because it was deliberately designed and does not exist in nature. It is unclear if the resulting agent has an RG classification or BMBL category because it is no longer an unmodified adenovirus. All of this would suggest that NIH review is called for under the draft Policy before the experiment can begin. At the same time, the specifics of the experimental set-up suggest that IBC review should be sufficient.

The NIH should address this ambiguity by clarifying: experiments involving agents that, in their unmodified form, already have a risk group designation should be classified in that risk group for purposes of the Policy even after modification, unless the experiment is reasonably anticipated to increase the agent's transmissibility, virulence, or immune evasion.

   b. **The NIH should include oversight of high-risk animal and plant experimental work in NIH-funded institutions**

While the Animal and Plant Health Inspection Service (APHIS), an agency within the U.S. Department of Agriculture (USDA), has primary federal responsibility for overseeing and managing the risks associated with animal and plant pathogen laboratory work, if the NIH is funding work in these fields—or if such work is taking place in NIH-funded institutions—it should provide oversight of this work. Its principal focus on this work should be to assess whether

[1] Draft Policy § IV-1. The Policy notes that experiments involving genetically modified versions of risk-group (RG) 1 agents may proceed after IBC or IBC-delegated review. See id. § IV-3.
[2] Id. § II.

proposed work will increase an animal or plant pathogen's capability for transmission, its potential lethality, and/or its capacity to avoid the immune response of its animal or plant host. The greatest potential risk would be the potential for a novel modified pathogen to cause an epizootic or epiphytotic, or even a panzootic or panphytotic event.

c. The NIH should provide greater oversight of experiments involving genetically modified RG1 agents that pose material risks

Under the current Guidelines, any proposed experiment for introducing drug resistance to an agent in a manner that "could compromise the ability to control disease agents in humans, veterinary medicine, or agriculture" requires NIH Director approval.[3] The draft Policy, by contrast, specifies that all genetic modifications to RG1 agents require only IBC or sub-IBC review.[4] The NIH should clarify that proposals to modify RG1 agents in a manner that is reasonably anticipated to materially increase the agent's transmissibility between humans, its virulence among humans or non-human animals or plants, or its ability to evade the immune system in eukaryotes should be subject to NIH review.[5]

d. The NIH should clarify the definition of "novel agent or organism."

The draft Policy defines a novel agent or organism as "[a]n agent or organism not existing in nature, deliberately designed, and possibly derived from multiple, different natural or synthetic sources (e.g., chimeras, or organisms generated by synthetic biology in conjunction with artificial intelligence)." Because it is impossible to rule out an agent or organism existing in nature, we believe that a novel agent would be better defined as "[a]n agent or organism not **known to exist** in nature…"

2. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

a. The NIH Should Reconfigure the Risk Groups to Focus on Epidemic and Pandemic Risk Rather Than Individual Threat

The draft Policy does not say whether it plans to continue using the risk-group classification system included in the current Guidelines. We urge the NIH to revise the risk-group classification system to better focus on epidemic and pandemic risk, specifically by classifying agents that are highly transmissible, and to which most people are immune naïve, at RG3 or RG4. At present, the Guidelines categorize agents based on their "relative pathogenicity for healthy adult humans," rather than their risk to society.[6] To take one example: The Guidelines allow scientists to handle

[3] See 2024 Guidelines § III-A-1.
[4] Draft Policy § IV-3.
[5] We recognize that such experiments are likely to be barred by the recent U.S. Government Policy for Stopping High-Risk Life Sciences Research. Nonetheless, we believe that it is worth avoiding creating an unintentional carveout in the policy for research involving modified RG1 agents that may pose substantial risks.
[6] See 2024 Guidelines Appendix B, tbl. 1.

resurrected 1918 influenza, which killed tens of millions of people when it first arose, in BSL-3 enhanced containment. But scientists studying certain tick-borne viruses, which are deadly but very unlikely to spread between humans, must do so in BSL-4 conditions. Likewise, H2N2 influenza—which killed more than a million people worldwide in a pandemic in 1957–1958—can be studied in BSL-3 enhanced containment. Though the draft Policy does not provide its RG ranking, it appears to contemplate continuing this policy.[7]

The most catastrophic risk of a lab accident or intentional pathogen release is the risk of sparking a major epidemic or a pandemic. A pathogen's virulence is only one factor to be considered in evaluating the appropriate biosafety procedures for its study. The NIH should reconfigure its RG system to consider transmissibility and societal immunity as key factors in RG ranking alongside virulence.

3. **Feedback on the implementation resources and areas in which additional guidance would be beneficial.**

a. The NIH Should Develop Guidance to Prevent the Creation of Key Mirror-Life Precursors

The creation of mirror bacteria could pose catastrophic risks to humanity and to the environment because such bacteria may be capable of evading most of life's existing defenses.[8] The recent U.S. Government Policy for Stopping High-Risk Life Sciences Research bars the U.S. government from directly supporting the creation of mirror organisms.[9] Yet the draft Policy does not mention mirror organisms or research into mirror biology. To be sure, any research proposing to create a mirror bacterium would presumably require NIH and IBC approval as an experiment involving a "novel agent" without preexisting categorization.[10] But a great deal of the science behind creating mirror life—that is, science that enables others to create a mirror bacterium—might take place without itself creating a full mirror bacterium.[11] Such endeavors may not fall within the draft Policy's definition of research subject to NIH or IBC review. We therefore urge the NIH to develop guidance to ensure that mirror-life precursor research is properly subject to NIH and/or IBC review, without unduly hampering useful research that does not study atypical chirality. The NIH may not be able to develop such guidance in time for the release of this version of this Biosafety Policy, but it should urgently pursue such guidance for subsequent updates, and should publicly signal in the finalized version of this Policy that it plans to urgently create such guidance.

348. N/A

I am responding: On behalf of an organization

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Scope of Research
Please clarify the work under Section IV-3. Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members, specifically the definition of transgenic organisms at BSL-1/ABSL-1.
We ask that the following be considered exempt from review by the IBC, as was proposed during the listening sessions:
• Research conducted with transgenic organisms at BSL-1/ABSL-1.
• Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes.
• Research with well-characterized cell lines.

Increased administrative burden
Please clarify in the policy or in implementation guidance to what extent the Principal Investigator must document adequate biosafety training for the research they will be conducting.
We suggest defining “periodically” within the policy as a time point established by the institutional IBC.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We suggest that the project description requirement in the IBC minutes to be very high-level, so that institutions are not required to reveal information that would allow the substance of a not-yet-published research project to be made available to the public. This would allow institutions to protect proprietary information of the research and the autonomy of the review process.

We suggest that the implementation guidance provide examples of incidents that are reportable to the NIH and non-reportable incidents that only require IBC review.
We ask the NIH to reconsider the requirement of publicly posting incident reports. We have concern that this requirement may lead to underreporting due to perceptions of the punitive nature of publicly displaying identifiable information and fear. If there is no change in the policy, we suggest that the name of the PI and NIH grant or contract number be removed from the public-facing website. As the responsibility of the National Biosafety Data and Safety Analysis Center is to independently aggregate, de-identify, and analyze laboratory biosafety incident data, near-misses and anomalies, trends in laboratory incidents would be available through this center, without publicly posting incident reports.

6. Other feedback relevant to this resource: We recommend moving the Risk Group categorization of agents from a published document to a live document so that the rapid pace of changes in risk group categorizations can provide the most value to biosafety professionals.

349. Ramesh Chandra

I am responding: On behalf of myself

Name: Ramesh Chandra

Name of Organization: University of Maryland, Baltimore

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): https://www.medschool.umaryland.edu/profiles/chandra-ramesh/

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: As Director of a university Viral Vector Core, I am concerned that the broader scope of this policy could add considerable paperwork to work already covered by institutional biosafety review. My staff and the investigators we serve would both spend more time preparing and updating documents.
The policy needs to clearly identify which activities are covered, which are outside its scope, and what documentation is actually necessary. This is especially important for routine AAV and lentiviral work and experiments using established cell lines.
Unclear requirements could lead to overlapping submissions and repeated requests for the same information. For a core facility, that additional work has a cost. It could reduce the time available for vector production and consultation, while researchers wait longer for materials and approvals.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): As Director of a university Viral Vector Core, I am concerned about the time and cost of requiring a completely new application every three years for unchanged, previously approved research. Core staff and investigators would spend time rewriting information that the IBC has already reviewed.

An important strength of maintaining one updated protocol is that it keeps the history of the work together. Related vectors, reagents, amendments, and safety decisions can be followed in one record. This helps investigators and biosafety staff prepare for reviews, audits, and inspections. If renewal or assignment to different review categories requires replacing or splitting these records, that history could become harder to follow without improving safety.

Our core produces vectors for multiple research groups. Repeated documentation on our side, followed by similar submissions from each investigator, could create substantial duplicate work. We may need additional administrative staff and could have to increase service fees to cover those costs. Researchers would then face both higher charges and more paperwork.

Please allow shorter renewals for unchanged, lower-risk work and shared protocols for related

constructs. Preserve the complete approval history and focus additional review on changes that affect the biosafety assessment.

3. Continued utility of Risk Groups: For the work we do, the safety assessment needs to consider the actual vector, what it carries, and how it is produced and used. A broad classification alone does not answer those questions.
My concern is that unclear guidance could result in extensive new documentation for closely related vectors, even when the relevant risks are already understood. Core staff would have to prepare these assessments, and investigators could face additional questions and delays before beginning their experiments.
Please provide clear examples for common AAV and lentiviral applications. Allow us to reference previously reviewed information and document what has changed, rather than repeat the entire assessment for every related construct. This would let researchers and biosafety staff concentrate on differences that matter.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): A process that requires extensive paperwork, recurring submissions, and substantial staff time is unlikely to encourage voluntary participation. Smaller organizations may not have someone available to manage these responsibilities.
From my perspective as a scientist and core director, access to practical help would be more useful than additional administrative requirements. Free training, straightforward forms, and affordable access to biosafety review would make participation more realistic.
NIH should clearly distinguish required activities from voluntary recommendations. Organizations should be able to use suitable existing records and procedures rather than create a second administrative system. Otherwise, the cost and workload could discourage the participation NIH is trying to encourage.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: My concern with additional reporting templates is that the same event could require several versions of the same information. Core staff and investigators could spend considerable time preparing laboratory records, institutional reports, NIH reports, and material for public posting.
The templates should allow information already recorded in institutional systems to be reused. Instructions must clearly explain which incidents require NIH notification and which are handled locally. Staff should not have to spend hours determining which reporting process applies.
Meeting minutes should record the safety discussion and decision without repeating the research application. NIH should also provide clear instructions for preparing public versions. Reviewing and removing personal or confidential information takes staff time and needs to be included when estimating the workload.

6. Other feedback relevant to this resource: The additional administrative work would fall on staff who already produce vectors, assist investigators, and manage existing requirements. NIH should assess the staffing and costs involved before implementation and consider financial support for this work.

Guidance should explain how existing protocols, amendments, reagent inventories, and approval histories will be carried forward. Laboratories should not have to reconstruct years of documentation simply because a protocol receives a new number or moves to a different review category. Linked records and reusable information would help preserve continuity.

I am also concerned about materials covered by Material Transfer Agreements. NIH should clarify how these materials will be handled during protocol renewal or migration. A change in protocol status should not lead to unnecessary repeat approvals or material-transfer paperwork when the material, permitted use, and safety risks remain unchanged.

Please provide sample renewal forms, shared-protocol examples, and clear instructions for documenting these transitions. A reasonable transition period is needed so that administrative changes do not interrupt vector production or researchers' access to previously approved materials.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We support the objective of proportionate, risk-based oversight of research involving biohazards. However, we have significant concerns about applying the Policy to non-NIH-funded research solely because it is undertaken at an institution that receives NIH funding.
New Zealand institutions already operate under established, compulsory and comprehensive national legislation for biological hazards. Extending NIH requirements to research that receives no NIH support would duplicate existing oversight and create significant administrative costs without necessarily providing a corresponding reduction in risk.
We recommend allowing non-US institutions to demonstrate that comparable national regulatory and institutional oversight is already in place. This would also be consistent with the NIH's existing approach - we recommend that the final Policy retain the host-country provision in Section I-C-1-b-(3). Under this approach, a foreign institution would attest in its Biosafety Assurance that research not supported by NIH is overseen under host-country law, using safety practices reasonably consistent with the Policy. It would identify the relevant national regulators, and NIH would retain the right to request information.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): We support tiered, risk-based oversight and recommend that NIH explicitly recognise regulatory systems outside the United States that provide oversight consistent with the Policy.
In New Zealand, biological risks are managed through established primary legislation including the Biosecurity Act 1993, Hazardous Substances and New Organisms Act 1996, and the Health and Safety at Work Act 2015. Genetically modified and other new organisms are subject to approval and containment requirements administered through the Environmental Protection Authority (EPA). Containment facilities are approved by the Ministry for Primary Industries (MPI), and Institutional Biological Safety Committees approve low-risk genetic modification under authority delegated by the Environmental Protection Authority.
Some elements of these frameworks are expressed differently from the draft Policy. New Zealand specifies containment as PC1–PC4 (under AS/NZS 2243.3 and the MPI/EPA containment standard) rather than BSL/ABSL, and we ask that NIH recognise equivalent international containment classifications. Definitions also differ: the draft Policy's definition of genetic modification includes stable alterations

introduced by passaging, chemical or radiological means, which New Zealand law generally does not treat as genetic modification. Requiring element-by-element alignment with the Policy would be impractical, even where overall standards of oversight are consistent.
We would therefore welcome an approach in which NIH requirements supplement existing national arrangements where an identifiable gap exists, rather than establishing a parallel oversight system.

3. Continued utility of Risk Groups: We support retaining Risk Groups as a baseline for risk assessment rather than using Biosafety Level as the primary measure of risk.
Risk Group and Biosafety Level serve different purposes. Risk Group informs assessment of the organism's inherent hazards, while the appropriate containment level should result from an activity-specific risk assessment considering factors such as experimental procedures, scale, exposure routes and genetic modifications.
This distinction is particularly important for genetically modified organisms, where modification may increase, decrease or leave unchanged the risk presented by the parental organism.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH guidance and resources may provide useful examples of good biosafety practice for research outside the Policy's scope. The University would welcome the opportunity to draw on NIH guidance where it adds value to existing practice. Nevertheless, we recommend that non-NIH-funded research at foreign institutions should be voluntary only, sitting alongside national oversight, rather than as a condition of an institution receiving NIH funding.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We support transparency in biosafety oversight, appropriate documentation and incident reporting. New Zealand universities are already subject to the Official Information Act 1982, which provides public access to institutional information. However, public posting of IBC minutes and incident reports raises concerns regarding privacy, staff safety, confidentiality, commercially sensitive information and intellectual property, particularly for institutions operating under non-US legislation such as New Zealand's Privacy Act 2020.
We ask that NIH specify the minimum information required, how information will be protected and whether it may be publicly disclosed. Foreign institutions should be able to redact or withhold information where disclosure would conflict with national law or legitimate privacy, commercial, intellectual property or security obligations.

6. Other feedback relevant to this resource: Institution-wide application would have significant resourcing implications, including additional biosafety review, administration, training, record keeping and reporting for projects receiving no NIH support.
NIH currently supports 0.1% of active projects at the University. Institution-wide provision would extend NIH requirements to an overwhelming majority of projects that receive no NIH support.
These costs would fall on research that NIH does not fund, without a corresponding reduction in risk where national oversight already applies.
We recommend that NIH:
• limit mandatory requirements to research with defined NIH funding;
• recognise overseas regulatory and institutional oversight that is reasonably consistent with the Policy, as provided for in Section I-C-1-b-(3) of the current NIH Guidelines;
• minimise duplication of reporting already required by national regulators;

• provide specific implementation guidance for foreign institutions.
We thank NIH for the opportunity to comment and would welcome further engagement as the Policy is finalised.

Uploaded File: Otago_NIH_biosafety_response_FINAL.pdf

Name of Organisation: University of Otago

Type of Organsiation: Academic Institution

The University of Otago is a leading research-intensive university in New Zealand, and values its long-standing research partnership with NIH. We share NIH's goal of biosafety oversight that is transparent, adaptive, accountable and proportionate to risk. Our comments focus on how the Policy would apply to non-NIH-funded research at institutions outside the United States that already operate under robust national regulatory frameworks.

1. **Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.**

We support the objective of proportionate, risk-based oversight of research involving biohazards. However, we have significant concerns about applying the Policy to non-NIH-funded research solely because it is undertaken at an institution that receives NIH funding.

New Zealand institutions already operate under established, compulsory and comprehensive national legislation for biological hazards. Extending NIH requirements to research that receives no NIH support would duplicate existing oversight and create significant administrative costs without necessarily providing a corresponding reduction in risk.

We recommend allowing non-US institutions to demonstrate that comparable national regulatory and institutional oversight is already in place. This would also be consistent with the NIH's existing approach - we recommend that the final Policy retain the host-country provision in Section I-C-1-b-(3). Under this approach, a foreign institution would attest in its Biosafety Assurance that research not supported by NIH is overseen under host-country law, using safety practices reasonably consistent with the Policy. It would identify the relevant national regulators, and NIH would retain the right to request information.

2. **Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).**

We support tiered, risk-based oversight and recommend that NIH explicitly recognise regulatory systems outside the United States that provide oversight consistent with the Policy.

In New Zealand, biological risks are managed through established primary legislation including the Biosecurity Act 1993, Hazardous Substances and New Organisms Act 1996, and the Health and Safety at Work Act 2015. Genetically modified and other new organisms are subject to approval and containment requirements administered through the Environmental Protection Authority (EPA). Containment facilities are approved by the Ministry for Primary Industries (MPI), and Institutional Biological Safety Committees approve low-risk genetic modification under authority delegated by the Environmental Protection Authority.

Some elements of these frameworks are expressed differently from the draft Policy. New Zealand specifies containment as PC1–PC4 (under AS/NZS 2243.3 and the MPI/EPA containment standard) rather than BSL/ABSL, and we ask that NIH recognise equivalent international containment classifications. Definitions also differ: the draft Policy's definition of genetic modification includes stable alterations introduced by passaging, chemical or radiological means, which New Zealand law generally does not treat as genetic modification. Requiring element-by-element alignment with the Policy would be impractical, even where overall standards of oversight are consistent.

We would therefore welcome an approach in which NIH requirements supplement existing national arrangements where an identifiable gap exists, rather than establishing a parallel oversight system.

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

We support retaining Risk Groups as a baseline for risk assessment rather than using Biosafety Level as the primary measure of risk.

Risk Group and Biosafety Level serve different purposes. Risk Group informs assessment of the organism's inherent hazards, while the appropriate containment level should result from an activity-specific risk assessment considering factors such as experimental procedures, scale, exposure routes and genetic modifications.

This distinction is particularly important for genetically modified organisms, where modification may increase, decrease or leave unchanged the risk presented by the parental organism.

4. **Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).**

NIH guidance and resources may provide useful examples of good biosafety practice for research outside the Policy's scope. The University would welcome the opportunity to draw on NIH guidance where it adds value to existing practice. Nevertheless, we recommend that non-NIH-funded research at foreign institutions should be voluntary only, sitting alongside national oversight, rather than as a condition of an institution receiving NIH funding.

5. **Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.**

We support transparency in biosafety oversight, appropriate documentation and incident reporting. New Zealand universities are already subject to the Official Information Act 1982, which provides public access to institutional information. However, public posting of IBC minutes and incident reports raises concerns regarding privacy, staff safety, confidentiality, commercially sensitive information and intellectual property, particularly for institutions operating under non-US legislation such as New Zealand's Privacy Act 2020.

We ask that NIH specify the minimum information required, how information will be protected and whether it may be publicly disclosed. Foreign institutions should be able to redact or withhold information where disclosure would conflict with national law or legitimate privacy, commercial, intellectual property or security obligations.

6. **Feedback on the implementation resources and areas in which additional guidance would be beneficial.**

Institution-wide application would have significant resourcing implications, including additional biosafety review, administration, training, record keeping and reporting for projects receiving no NIH support.

NIH currently supports 0.1% of active projects at the University. Institution-wide provision would extend NIH requirements to an overwhelming majority of projects that receive no NIH support.

These costs would fall on research that NIH does not fund, without a corresponding reduction in risk where national oversight already applies. We recommend that NIH:

- limit mandatory requirements to research with defined NIH funding;
- recognise overseas regulatory and institutional oversight that is reasonably consistent with the Policy, as provided for in Section I-C-1-b-(3) of the current NIH Guidelines;

- minimise duplication of reporting already required by national regulators;
- provide specific implementation guidance for foreign institutions.

We thank NIH for the opportunity to comment and would welcome further engagement as the Policy is finalised.

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/18/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): RNA Biology of Human Cells

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am writing to recommend the removal of language in the “Draft NIH Biosafety Policy for Research Involving Biohazards” (NOT-OD-26-112) which is incorrect and misleading, as it implies that treatments which do not change an organisms genetic information would. Specifically, a portion of the below excerpt:

"Genetic Modification:
The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
Have the potential for one or more cycles of replication in a cell; or
Can be transcribed or translated; or
The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means."

In the third bullet point: introduction of molecules which can be transcribed or translated does not constitute genetic modification. In usage of this term both by laypeople and expert biomedical researchers such as myself, genetic modification is restricted to manipulations which will change or add to the existing sequence of an organisms genetic material (DNA) in a lasting fashion. This does not include the inherently temporary introduction of messenger RNA molecules.

The draft must be amended to reflect that introduction of nucleic acids which do not persist long term in the cell does not constitute genetic modification.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): No comments at this time.

3. Continued utility of Risk Groups: No comments at this time.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No comments at this time.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: No comments at this time.

6. Other feedback relevant to this resource: No comments at this time.

Re: Draft NIH Biosafety Policy for Research Involving Biohazards, Notice Number NOT-OD-26-112

Dear NIH Office of Science Policy:

Yale University appreciates the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. Yale supports NIH's goal of modernizing federal biosafety oversight and creating a more comprehensive framework for research involving biological hazards. We also support the use of delegated review as a proportionate mechanism for lower-risk activities. However, several provisions of the draft would substantially expand institutional review, reporting, and public-disclosure obligations without sufficiently distinguishing activities that present meaningful biosafety risk from routine or historically exempt research. In their current form, these provisions could divert investigators, Biological Safety Officers, Institutional Biosafety Committees, and institutional resources away from higher-risk work while weakening the candid reporting culture on which effective biosafety programs depend.

Our principal recommendation is that NIH revise the final policy around a clear, risk-based framework. The policy should preserve well-established exemptions for minimal-risk research, align the level of review with the nature and magnitude of the hazard, avoid duplicating oversight already provided under other federal requirements, and permit institutions to concentrate their biosafety resources on activities that present credible risks to personnel, public health, or the environment.

1. Preserve a risk-based scope and established exemptions

The draft policy broadly includes genetically modified cells, viruses, and organisms; primary cells that may contain adventitious agents; plasmids; transgenic organisms; well-characterized cell lines; and biological toxins not on the Select Agent list. Without risk-based qualifiers or a dedicated exclusions section, this scope would bring large categories of routine, low-risk, and historically exempt research into Institutional Biosafety Committee (IBC) oversight. The result would be a substantial increase in registrations and delegated reviews even when the underlying activity has little or no plausible capacity to cause disease, toxicity, environmental harm, or loss of containment.

The current exemptions reflect decades of institutional experience with categories of research that have not presented significant risks to human health or the environment. Retaining those distinctions would allow IBCs to continue directing their attention to work with more consequential hazards while preserving institutional authority to review low-risk activities locally. NIH should revise or eliminate an established exemption only when scientific evidence or operational experience demonstrates that it no longer provides adequate protection. The final policy should also include a transparent process for adjusting exclusions as research practices and technologies change.

The final policy should expressly exclude, or otherwise remove from mandatory federal review, five categories that generally present minimal biosafety risk: genetically modified RG1 agents; transgenic organisms maintained at BSL-1 or ABSL-1; low-risk plasmids and replication-incompetent, non-integrating vectors expressing reporter or comparably low-risk transgenes; well-characterized cell lines; and non-Select Agent toxin proteins that do not meet an objective potency threshold. Institutions should remain free to review these activities locally when experiment-specific circumstances warrant additional oversight.

The plasmid category illustrates the practical scale of the proposed expansion. Yale laboratories routinely create and modify large numbers of plasmids as part of iterative experiments involving low-risk genes, and no reliable institution-wide inventory exists because constructs may change repeatedly within a single research program. Requiring each such construct or variation to enter an IBC or delegated-review process would impose substantial documentation and review effort without a corresponding increase in biosafety protection.

Yale therefore recommends that NIH add a dedicated exclusions section; retain the exemptions in Section III-F and Appendix C of the April 2024 NIH Guidelines unless an evidence-based rationale supports a change; preserve certified host-vector, tissue-culture, and qualifying transgenic-rodent exemptions; and permit institutions to determine whether otherwise excluded activities warrant local review. Federal reporting, assurance, public-minutes, and enforcement requirements should not attach solely because an institution voluntarily elects to review an excluded activity.

2. Retain essential risk-assessment guidance from the current NIH Guidelines

The draft policy replaces a detailed, longstanding framework with a shorter policy document but does not preserve several resources that institutions rely on to conduct consistent risk assessments. Appendix B's classification of etiologic agents by Risk Group remains a practical starting point for evaluating agents, particularly because the BMBL primarily uses biosafety levels rather than providing a comprehensive Risk Group classification. Other current provisions continue to provide valuable operational guidance including the experiment categories and exemptions in Section III, the natural-exchanger provisions in Appendix A, the Major Actions framework in Appendix D, the toxin framework in Appendix F, the physical and animal containment provisions in Appendices G and M, the large-scale provisions in Appendix K, and the plant-containment provisions in Appendix P.

Yale recommends that NIH retain these materials within the final policy or republish them as authoritative companion guidance. At a minimum, NIH should preserve Appendix B's Risk Group framework and the established toxin potency thresholds, and should ensure that institutions have a stable federal source for physical containment, animal containment, large-scale research, and other specialized risk assessments.

3. Refine the definition of genetic modification

The draft definition of genetic modification includes stable genomic alterations arising through passaging and through chemical or radiological means. As written, this language could encompass routine subculturing, the accumulation of undefined laboratory adaptations, and activities whose principal risks are chemical or radiological rather than biological. Researchers and IBCs may be unable to determine when ordinary passaging has produced a change covered by the policy, and IBCs generally are not the appropriate oversight body for hazards arising solely from chemical or radiological mutagens.

NIH should remove chemical and radiological means from the definition unless the resulting biological change itself creates a reasonably foreseeable increase in biosafety risk. Passaging should be limited to deliberate culturing under selective conditions that could reasonably be expected to increase virulence, pathogenicity, transmissibility, host range, tissue tropism, resistance, or another risk-relevant characteristic. Transient, nonintegrating materials that do not modify the genome should likewise remain outside the definition when they do not otherwise create a covered biological hazard.

4. Align review pathways with actual risk and existing oversight

Several review categories do not appear proportionate to the risks presented. Primary human cells and tissues of unknown infectious status are already addressed through the Occupational Safety and Health Administration Bloodborne Pathogens Standard and established institutional programs. Requiring full IBC review merely because an adventitious agent cannot be excluded would duplicate oversight and could place potentially contaminated material under a more stringent pathway than direct work with a known RG2 agent. Routine primary cells handled under universal precautions should be eligible for delegated review, with full committee review reserved for materials known or reasonably suspected to contain an RG3 or RG4 agent or for procedures likely to propagate, amplify, concentrate, or aerosolize such an agent.

The final policy should also state expressly that wild-type RG1 biological agents are outside its scope and should use that exclusion consistently across the scope, definitions, and review categories. Conversely, work with RG2 human pathogens warrants full IBC consideration rather than automatic delegated review because the relevant risk depends on the agent, procedures, quantities, routes of exposure, and available countermeasures. IBCs should retain authority to elevate any delegated matter when the institutional risk assessment warrants full committee review.

5. Remove the requirement to publicly post individual incident reports

Yale strongly supports timely reporting, investigation, and shared learning from biosafety incidents. We are concerned, however, that mandatory public posting of individual incident reports, including lower-risk incidents reviewed only by the institution, will undermine those goals. Even when the affected individual is not named, the combination of the Principal Investigator's name, research material, incident circumstances, personnel role, medical response, location, root cause, and corrective actions may permit identification of an individual, laboratory, or specialized research program. Public posting may therefore discourage prompt reporting of minor incidents, suspected exposures, and near misses, weakening the candid reporting culture that effective biosafety programs have worked to build.

Event-specific disclosure may also create research and institutional security concerns. Identifying a Principal Investigator and describing distinctive agents, animal models, containment practices, facility circumstances, or corrective measures could reveal sensitive information about research programs or security controls. Any transparency requirement should therefore be designed to avoid exposing details that could facilitate misuse, targeting, or disruption of personnel, laboratories, or institutional operations.

NIH should require applicable reports to be submitted to NIH and maintained institutionally, while using the National Biosafety Data and Safety Analysis Center to publish aggregated, deidentified analyses of recurring hazards, contributing factors, corrective actions, and national trends. Incidents requiring only institutional or IBC review should not be publicly posted. If NIH

retains a public-disclosure requirement, it should be limited to standardized summaries of confirmed significant incidents, should not identify the Principal Investigator or include combinations of details that could reasonably identify affected people or programs, and should permit delayed publication until investigations, occupational-health evaluations, corrective actions, and related processes are complete.

6. Establish clear thresholds for NIH incident notification

Immediate NIH notification should be limited to incidents presenting a credible and significant risk of infection, transmission, environmental release, or material loss of containment. The final policy should more precisely define the circumstances that constitute a suspected laboratory-acquired infection, a credible community risk or exposure, treatment beyond basic first aid, and a substantive compliance violation. Precautionary medical evaluation, diagnostic testing, vaccination, or prophylaxis should not independently make an event reportable when a meaningful exposure is not reasonably suspected. Likewise, equipment or facility failures should require federal notification only when containment is compromised or a credible risk is created. A component failure that is managed by functioning redundant systems should remain subject to institutional documentation and review.

The 24-hour period should begin when the BSO, IBC Chair, IBC office, institutional official, or another designated authority has sufficient information to reasonably determine that the event meets NIH criteria. NIH should distinguish immediate notification, routine reporting, and institution-only documentation, and should limit federally reportable compliance violations to substantive failures that materially compromise biosafety oversight or result in covered research being conducted without required approval or containment.

7. Clarify delegated review and public-minutes requirements

Delegated review can improve proportionality, but its value will be diminished if every approval must later be “reported in full” in publicly posted IBC minutes. The final policy should clarify that a structured summary or consent agenda satisfies this requirement. Such a summary could identify the institutional registration number, general research category, type of action, broad class of biological material, containment level, approval date, and material conditions without reproducing a protocol-level narrative or risk assessment. Purely administrative changes that do not affect the biosafety assessment should not require individual reporting in public minutes.

The policy should also permit ecological or environmental expertise required for review of gene drive modified organisms to be supplied by non-voting consultants or ad hoc experts. Requiring such specialists to serve as voting members when their expertise is needed only intermittently can create unnecessary quorum and attendance complications without improving the quality of review.

8. Use a risk-based renewal framework

A mandatory de novo review every three years would substantially increase workload for investigators, biosafety staff, IBC members, and institutional officials, including for research that has not materially changed.

NIH should permit approvals of up to five years, supported by annual investigator certification, prospective review of risk-relevant amendments, and authority for the IBC to shorten an approval period when warranted. Unchanged research should be eligible for streamlined renewal by a BSO or qualified IBC delegate after confirmation that the existing risk assessment, containment, and approval conditions remain appropriate. The policy should also permit

reasonable administrative extensions when a complete renewal has been submitted before expiration and institutional review remains in progress.

9. Apply objective thresholds to toxins and self-aggregating proteins

The draft's broad toxin definition could extend federal oversight to ordinary proteins and peptides that can cause harm only at high doses or under circumstances that do not present a meaningful laboratory biosafety risk. NIH should retain objective potency thresholds from the current Guidelines and distinguish review pathways according to potency, quantity, concentration, physical form, route of exposure, aerosol potential, and proposed manipulation. The final policy should also clarify that delegated review applies to non-Select Agent toxin proteins and peptides, not only to "biological toxin proteins."

IBC oversight of self-aggregating proteins should likewise depend on evidence of a credible biosafety hazard rather than aggregation alone. Classical mammalian prions should remain within IBC purview. Other protein assemblies should be assessed according to evidence of persistent self-propagating seeding, cellular or tissue spread, experimental transmissibility, resistance to decontamination, source and concentration, and the proposed routes of exposure. Routine work with monomeric proteins or aggregates lacking evidence of biological propagation should not automatically require full IBC review.

10. Clarify review of emerging, novel, and zoonotic agents

Section IV-1 should not require NIH review solely because an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum-containment recommendation in the BMBL. The BMBL is not an exhaustive inventory, and the absence of an entry does not itself establish elevated risk. Mandatory federal review should be limited to cases in which the absence of an established classification creates material uncertainty concerning appropriate containment or the potential for serious human, community, or environmental harm.

NIH should permit IBCs to make and document an institutional risk assessment using closely related agents, published evidence, and other authoritative information when adequate information is available. When federal review is required, institutions should be able to initiate work at a conservatively selected containment level unless NIH identifies a specific reason the work should not proceed. NIH should establish target review timelines and maintain a searchable repository of determinations that institutions may rely on for the same or materially equivalent agents, constructs, attenuations, and experimental activities.

11. Provide a realistic transition for ongoing research

Six months is not sufficient for institutions to revise policies, registrations, electronic systems, training, websites, reporting processes, and committee workflows while also reviewing a substantially expanded portfolio of ongoing research. Yale currently has more than 1,000 principal investigators using biological materials, more than 6,000 laboratories, approximately 710 active registrations involving recombinant or synthetic nucleic acid molecules, and more than 500 IACUC protocols, including over 400 involving mice. Many laboratories also maintain extensive collections of cell lines and plasmids that have accumulated over years of research. One long-established Yale laboratory alone maintains nearly 900 cell lines, approximately two-thirds of which are human. Requiring immediate re-registration and review of these previously approved or exempt activities would create a major administrative surge with limited safety benefit.

Yale recommends an implementation period of at least one year after publication of the final policy. Existing approvals should remain valid through their current expiration dates, and previously approved or institutionally reviewed activities should transition at their next scheduled renewal. NIH should publish final definitions, templates, reporting criteria, technical specifications, and implementation guidance before the transition period begins and should provide a corrective-action period before imposing enforcement for implementation-related deficiencies. NIH should also assess the personnel and financial burden of the final requirements, including the cumulative effect on investigators, IBCs, biosafety programs, animal-care programs, and institutional systems.

Because the draft would create new obligations across investigators, IBCs, biosafety offices, animal-care programs, information systems, and institutional administration, Yale also recommends an independent assessment by the U.S. Government Accountability Office of the personnel, financial, and operational consequences of the final framework. Such an analysis should evaluate both direct compliance costs and the opportunity cost of redirecting biosafety expertise from higher-risk research to routine or minimal-risk activities.

Before finalizing the policy, NIH should also provide additional time for consultation and extend the public-comment process. Further listening sessions would allow NIH to test whether the revised framework responds to the operational concerns raised by research institutions and to clarify how institutional discretion, exclusions, and delegated review will function in practice. Additional time would also enable professional organizations, including ABSA International and its affiliates, to collect broader data on investigator workload, staffing needs, implementation costs, and the likely effects on institutional reporting cultures.

Conclusion

Yale supports NIH’s effort to modernize and unify biosafety oversight. A successful final policy should strengthen the review of research presenting meaningful risk while preserving the flexibility, exemptions, and institutional judgment that have allowed IBCs to direct attention to the activities that most warrant scrutiny. Revising the draft to incorporate clear risk thresholds, retain established guidance, protect candid incident reporting, avoid duplicative oversight, and provide a workable transition will better advance the shared goals of safety, accountability, scientific progress, and public trust.

Sincerely,

Michael Crair

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Re: Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)
To the NIH Office of Science Policy:
I am Researcher and Professor at UC Santa Cruz with over 25 years of experience in microbiology. Of course I appreciate the idea to modernize biosafety oversight and agree that the NIH Guidelines, written around recombinant DNA, need updating. My concerns below are meant to help the final policy achieve its safety goals without undermining them.
1. Scope and the definition of biohazards
Extending oversight beyond recombinant and synthetic nucleic acids to all biohazards is a major change. I am concerned that "known or potential risk to human health" is broad enough to sweep in large amounts of routine, low-risk work, such as well-characterized BSL-1 organisms and standard clinical or environmental samples. Without clear, objective criteria and explicit exemptions for such work, institutions will likely over-report and over-review to avoid noncompliance. That would bury researchers an IBCs in low-value submissions and pull attention from higher-risk research. I urge NIH to define the scope with concrete, testable thresholds and to publish worked examples of covered and non-covered activities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 2. Tiered oversight and administrative burden
Please consider a risk-calibrated, tiered structure is the right goal. The current draft adds new responsibilities for investigators and IBCs, including a Biosafety Assurance, expanded documentation, standardized incident reporting, and new minutes requirements. Many institutions, especially smaller ones and those without dedicated biosafety staff, already operate IBCs with limited resources. If the lowest tier is not truly streamlined, the policy will increase burden while claiming to reduce it. I recommend that NIH:
• Estimate the expected burden on institutions and investigators, and publish it.
• Allow expedited or delegated review for clearly defined low-risk categories.
• Specify what accountability measures apply at each tier, so responsibilities are clear and not duplicative.

3. Continued utility of Risk Groups: 3. Transparency requirements
Public transparency is a legitimate value, and I support it. But expanded disclosure requirements must be balanced against the protection of confidential and proprietary information, unpublished research, and the personal information and safety of investigators and IBC members, who have faced harassment in some contexts. NIH should specify what must be public, in what form, and with what redaction protections, so that institutions are not left to guess and committee members are not discouraged from serving. Transparency should also be weighed against biosecurity: detailed public postings of protocols or agent-specific information could create risks of their own.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): 4. Risk Groups versus Biosafety Levels
Risk Groups are a useful starting point for risk assessment, but they were designed for unmodified agents and do not capture the effect of genetic modification, the specific procedures performed, or the containment available. The BMBL's agent-specific, procedure-based approach to assigning BSLs better reflects actual risk. I recommend that the final policy treat Risk Groups as one input among several, not a rigid baseline, and require assessment of the specific modification, procedure, and scale, with clear guidance on when and why a modified agent should move up or down in oversight.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 5. Compliance, enforcement, and non-NIH-funded research
Applying the policy to non-NIH-funded work at any institution that receives NIH funding gives it broad reach, and I am concerned about fairness and feasibility. Institutions may have to oversee privately or industry-funded work under NIH rules without NIH support for the added cost. I encourage NIH to clarify the legal and administrative basis for this extension, consider phased applicability, and rely on incentives, such as technical assistance and recognition of voluntary adoption, as much as on penalties.
Enforcement should distinguish good-faith reporting of incidents from willful noncompliance. Otherwise institutions and investigators will have reason to under-report, and NIH will lose the information it needs to improve safety.

6. Other feedback relevant to this resource: 6. Implementation resources and guidance
A policy this broad will only work if institutions can implement it. I request that NIH:
• Provide a realistic transition period of at least [12–24] months, with clear effective dates.
• Release plain-language guidance, decision tools, and sample SOPs before the policy takes effect.
• Provide IBC training and consider funding or supplements to support biosafety infrastructure.
• Pilot the incident reporting and minutes templates with a range of institution types and revise them based on feedback.

Description: Conclusion I support NIH's aim of strengthening biosafety oversight in proportion to risk. To succeed, the final policy needs a precisely bounded scope, a truly streamlined low-risk tier, balanced transparency, flexible risk assessment, enforcement that encourages reporting, and adequate time and resources for implementation. Thank you for considering these comments. Sincerely, Karen Ottemann, Distinguished Professor at UC Santa Cruz

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): infectious diseases epidemiology, global biosecurity

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed policy is a constructive and important development because it broadens oversight beyond recombinant or synthetic nucleic acid molecules to include wild-type biological agents, genetically modified organisms, toxins, prions and other self-aggregating proteins [1,2].
However, the proposed scope remains focused largely on physical laboratory research, while biological capability may increasingly develop across a digital-to-biological pathway before conventional laboratory oversight is triggered. AI-generated biological designs may be developed in silico, transferred to a synthesis provider or cloud laboratory, and subsequently assembled or experimentally validated through an automated platform [3-8].
The policy should clarify whether the following activities fall within scope:
• AI-generated, AI-modified or AI-optimised biological sequences, proteins, genomes or other biological designs;
• biological foundation models and genome-language models;
• computational designs intended for synthesis, assembly or experimental validation;
• cloud-accessible and automated laboratories;
• biological foundries integrating computational design with high-throughput experimentation; and
• AI systems used to optimise host range, toxicity, resistance, immune escape, environmental persistence or other biologically consequential properties [3-8].
The recent demonstration that AI-designed bacteriophages could be generated, synthesised and experimentally shown to be viable and biologically functional illustrates why this issue requires attention [3]. The bacteriophages were not human pathogens and should not be interpreted as an imminent human-health threat. Their importance is that they demonstrate a pathway from AI-generated biological designs to functional biological systems.
The policy should distinguish between routine AI-assisted analysis and AI used to design, generate, modify or optimise biological systems. It should also distinguish computational outputs intended only for theoretical analysis from designs intended for synthesis, assembly, experimentation or deployment. Enhanced oversight should be linked to intended use and potential consequences, rather than triggered by the mere use of AI [4-8].

A further consideration is the use of commercial intermediaries. Researchers may obtain synthesis, screening, sequencing, robotic experimentation or other services from external providers. Responsibility may therefore be distributed across researchers, institutions, commercial providers and remote laboratory platforms. The policy should clarify institutional accountability for outsourced work and require applicants to identify relevant providers and the types of activities being conducted [6-8].

I recommend that NIH add a digital biological design and capability component to the policy or provide supplementary guidance addressing this area. This would not require NIH to treat all AI-enabled biology as hazardous. Rather, it would ensure that projects involving potentially consequential biological design are identified early enough for proportionate review.

NIH should also consider a prospective, tiered registry for higher-risk AI-enabled biological design research. The registry could initially cover NIH-funded research involving AI-generated or AI-optimised biological designs intended for synthesis, laboratory assembly or experimental validation. It should record high-level information about the research purpose, biological system, intended downstream activity, use of external providers and biosafety review status without requiring disclosure of sensitive sequences or proprietary methods.

Such a registry could support transparency, accountability, horizon scanning and early assessment of dual-use implications [4,5,9-11]. It should protect legitimate research, intellectual property and national security through tiered access and appropriate confidentiality protections.

This approach is consistent with the distinction between event-based and capability-based surveillance. Existing surveillance asks whether a biological event has occurred. As biological design becomes increasingly digital, NIH should also consider what capabilities are becoming possible, how accessible they are becoming and whether separate advances in AI, synthesis and automation are converging [9-11].

The purpose should be to support expert assessment and preparedness, not to classify legitimate research or researchers as suspicious. Overall, the proposed scope is an appropriate foundation, but it should be expanded or supplemented to address in silico biological design, outsourced experimentation, cloud laboratories, automated biofoundries and the convergence of AI with synthetic biology.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered approach is appropriate and preferable to applying identical requirements to all biological research. The proposed distinction between NIH-level and institutional-level review should reduce unnecessary administrative burden while retaining central oversight for activities with broader or less predictable consequences [1,2].

However, risk assessment should not rely solely on the biological agent, Risk Group or physical containment level. These remain important foundations, but they do not fully capture the risks associated with emerging AI-enabled biological design and technology convergence [3-8].

Risk assessment should also consider:

- the biological function being designed or modified;
- the ability of the design to affect human, animal or plant health;
- host range, transmissibility, environmental persistence or immune escape;
- the potential for increased toxicity, resistance or pathogenicity;
- the extent to which the work reduces existing technical barriers;
- whether the system is novel or poorly characterised;
- whether the design is intended for synthesis, assembly or experimental validation;
- the availability of commercial synthesis or cloud-laboratory services;
- whether several individually low-risk activities are being combined; and
- the degree of automation, remote accessibility and transferability [3-8].

I recommend a two-dimensional risk model. The first dimension should describe the intrinsic biological hazard of the agent, construct or system. The second should describe the capability enabled by the research, including the extent to which the work increases the ability to design, synthesise, modify or deploy a biological system.

This would address situations in which an agent may have a low traditional Risk Group classification but the research substantially increases biological capability. It would also assist with projects in which no conventional pathogen is involved but several technologies combine to reduce the barriers between biological design and implementation [3-8].

NIH-level review should be considered for research that:

- involves RG3 or RG4 agents or equivalent hazards;
- seeks to lower containment for higher-risk agents;
- involves deliberate administration of higher-risk biological products;
- uses AI or automated systems to generate or optimise potentially consequential biological designs;
- links computational design directly to synthesis, assembly or experimental validation;
- creates a capability that could be readily transferred to other systems;
- involves a novel combination of technologies for which existing classifications are inadequate; or

• is distributed across multiple institutions or commercial providers in a way that complicates accountability.

Institutional review should remain appropriate for lower-risk work involving well-characterised systems, established containment requirements and limited potential for harmful capability enhancement. Delegated review may be appropriate for clearly defined low-risk categories, but not where novel AI-enabled designs, automated optimisation or technology convergence make the risk difficult to characterise.
The policy should include a clear escalation mechanism. An IBC should be able to refer a project to NIH when the risk classification is uncertain, the work does not fit an existing category, the project involves a new AI-enabled design capability, several individually low-risk technologies are being combined, or the institution lacks the necessary expertise.

The tiered model should also be adaptive. NIH should periodically review emerging technologies, incident data, scientific developments and evidence from horizon scanning to determine whether additional categories require central oversight [5-8].

3. Continued utility of Risk Groups: Risk Groups remain useful as a baseline because they provide a common starting point for assessing the inherent hazard of known biological agents. They are valuable for communicating broad biological risk and supporting consistent institutional decision-making [1,2]. However, Risk Groups should not be treated as a complete project-level risk assessment when organisms or biological systems are genetically modified, AI-designed, computationally optimised or placed in a new biological context [1,3-8].

Risk Groups generally describe the properties of an existing biological agent. They may not adequately capture:

• altered host range;
• altered tissue tropism;
• increased environmental stability;
• immune evasion;
• increased toxicity;
• antimicrobial or antiviral resistance;
• altered transmission characteristics;
• changes in replication or persistence;
• novel combinations of genetic elements; or
• AI-designed systems without a close natural analogue [3-8].

BSL and ABSL classifications remain essential for determining containment practices, facilities, equipment and operational controls. However, they should not be treated as a complete assessment of the biological or societal risk posed by a project.

The policy should make clear that RG and BSL/ABSL address different questions:

• Risk Group primarily describes the inherent hazard of the agent or biological system.
• BSL/ABSL describes the containment and operational controls required.
• A project-level risk assessment considers how the modification, experimental purpose, host, route of exposure, scale, automation and downstream use alter overall risk.

For genetically modified or AI-designed systems, the assessment should consider both the starting biological material and the properties or capabilities that the research may create. A modified RG2 agent should not automatically be treated as equivalent to the unmodified agent if the modification changes relevant biological characteristics. Conversely, a non-pathogenic or RG1 system may warrant additional review if the research creates a novel capability with uncertain consequences [3-8].

The policy should provide guidance for systems that do not fit existing RG classifications. IBCs should document the starting agent or system, the genetic or computational modification, the intended biological function, the expected change in hazard, plausible unintended effects, containment requirements and whether the work increases a capability relevant to public health or biosecurity.

I recommend retaining RG and BSL/ABSL as foundational frameworks while adding a supplementary capability and modification assessment for higher-risk or uncertain projects. This would preserve the value of existing biosafety frameworks while reducing the risk that novel AI-enabled biology is classified only according to the closest known agent.

The AI-designed bacteriophage study provides an example of why this additional assessment may be useful. The organisms were not human pathogens, but the research demonstrated that genome-language models can contribute to the generation of complete, viable biological systems [9].

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary compliance is important because significant biological capability is developed outside the direct scope of NIH funding, including in biotechnology companies, commercial synthesis providers, cloud laboratories, automated biofoundries and other distributed research environments [1-8].

The NIH should encourage voluntary compliance through a framework that is proportionate, accessible and beneficial to participating organisations. Possible mechanisms include:

- a voluntary institutional registration or assurance pathway;
- model biosafety and responsible-AI policies;
- standardised templates for risk assessment and incident reporting;
- access to training and educational materials;
- recognition for institutions that adopt NIH-aligned oversight;
- confidential consultation with NIH or designated technical experts;
- a voluntary registry for higher-risk AI-enabled biological design research; and
- opportunities for commercial providers and cloud laboratories to demonstrate alignment with the policy [3-8].

The voluntary framework should be available to research that is not NIH-funded but is similar in nature to work covered by the policy. It should also address activities between computational research and physical experimentation, including AI-generated designs, outsourced synthesis, cloud laboratories and automated biological platforms.

A voluntary registry could function as a trusted transparency and horizon-scanning mechanism rather than solely as an enforcement tool. Researchers should be able to register high-level information without disclosing sensitive sequences, proprietary methods or commercially confidential details. Registration could record the broad research purpose, type of biological system, use of AI for generation or optimisation, intended synthesis or experimental activity, use of external providers and institutional review status.

Voluntary compliance is more likely if NIH distinguishes responsible disclosure from evidence of misconduct. Institutions and researchers may be reluctant to report emerging technologies if registration automatically triggers punitive action or public disclosure. The system should support early consultation, learning and proportionate risk management [5-8].

NIH should also consider partnerships with DNA synthesis providers, cloud laboratories, automated foundries, scientific publishers, preprint repositories and relevant professional societies. These organisations may observe changes in biological capability earlier than government agencies or

individual institutions [6-8].
Voluntary compliance should not replace clear minimum requirements where significant risks are foreseeable. It is most appropriate for emerging or uncertain activities, while clearly defined high-risk activities should remain subject to mandatory review.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The use of standardised incident-reporting and meeting-minute templates should improve consistency, completeness and comparability across institutions. It should also help NIH identify recurring problems and emerging patterns that may not be apparent from individual reports [1,2].
The incident template should distinguish clearly between confirmed laboratory-acquired infection, potential exposure, loss of containment, release with possible community risk, animal escape or injury, non-compliance, failure to obtain or maintain IBC approval, equipment or containment failures, errors in biological design or experimental execution, and incidents involving outsourced or cloud-laboratory activities.
For incidents involving AI-enabled biology or automated laboratory systems, the form should include optional fields identifying whether:
• AI or automated design tools were involved;
• the incident occurred during computational design, synthesis, assembly, experimentation or analysis;
• an external provider was involved;
• a screening, quality-control or containment safeguard failed;
• the incident revealed a gap in the existing risk classification; or
• institutional procedures require updating.
These fields should not require sensitive technical details in a public-facing report. NIH should provide clear guidance on what information should be publicly reported and what information should be submitted confidentially.

The templates should also record corrective and preventive actions, including immediate response, medical or occupational health follow-up, containment and decontamination, notification and escalation, root-cause analysis, corrective action, responsible personnel and review of whether the action was effective.

The meeting-minute template should demonstrate that the IBC considered relevant risk factors without requiring minutes to reproduce every technical detail. It should include fields for:

- project title and responsible investigator;
- biological agents, constructs or systems considered;
- relevant RG and BSL/ABSL classifications;
- genetic, computational or AI-enabled modifications;
- use of synthesis providers, cloud laboratories or automated platforms;
- key risk considerations;
- uncertainty, dissenting views or unresolved issues;
- conditions of approval;
- containment and monitoring requirements;
- incident-reporting obligations;
- decision and vote;
- conflicts of interest; and
- follow-up actions and review dates.

The template should allow institutions to document uncertainty. A project may be approved with conditions while further information is obtained, or referred to NIH because the IBC cannot confidently classify the activity.

This is particularly important because recent studies have identified potential limitations in existing safeguards, including adversarial prompting of DNA language models, recovery of misuse-relevant capabilities through fine-tuning, limitations in nucleic-acid screening systems and circumvention of screening through fragmented orders across multiple providers [3-6].

Public-facing reporting can improve transparency and accountability. However, reports may expose personal information, commercially confidential information, sensitive pathogen information or operational details that could facilitate misuse. NIH should provide guidance on redaction, confidentiality and the distinction between publicly reported and confidentially submitted information.

regulate fragments as select agents. Nature Communications. 2026;17:3189. doi:10.1038/s41467-025-67955-3.

6. Other feedback relevant to this resource: The implementation resources should include practical guidance for institutions, IBCs, investigators and commercial providers. NIH should provide examples addressing emerging forms of biological research rather than relying only on conventional laboratory scenarios [1-5].

Additional guidance would be beneficial on:

• how to classify AI-generated or AI-optimised biological designs;
• when computational biological research enters the scope of the policy;
• how institutions should oversee work outsourced to cloud laboratories or commercial providers;
• who is responsible for biosafety and biosecurity when research is distributed across multiple organisations;
• how to apply RG and BSL/ABSL frameworks to novel or synthetic biological systems;
• how to assess technology convergence where several individually low-risk activities are combined;
• when delegated review is appropriate;
• when an IBC should refer a project to NIH;
• how to report incidents involving automated or remote laboratories;
• what information should be publicly reported and what should remain confidential;
• how to document AI use without requiring disclosure of proprietary models or prompts; and
• how to distinguish routine AI-assisted analysis from AI-enabled biological design [3-8].

NIH should consider publishing a decision tree or risk-assessment tool that begins with the proposed biological outcome rather than simply asking which agent is being used. It could ask:

1. Is a biological agent, construct, sequence, protein or organism being generated, modified or optimised?
2. Is AI being used to generate or optimise a biological property?
3. Is the output intended for synthesis, assembly or experimental validation?
4. Could the work alter host range, pathogenicity, toxicity, resistance, persistence, immune evasion or transmission?
5. Is the work being conducted through an external provider, cloud laboratory or automated biological facility?
6. Does the project combine multiple technologies that reduce the barriers between design and implementation?
7. Does the project fit an existing RG or BSL/ABSL category?
8. If not, should the project be referred to NIH or an expert review group?

Worked examples should address AI used to analyse sequencing data, protein-structure prediction, design of non-pathogenic enzymes, optimisation of viral vectors, generation of novel genomes for synthesis, cloud-laboratory experimentation and projects combining AI design, DNA synthesis and automated experimentation.

AI-enabled biology is developing rapidly, and static policy categories may become outdated. NIH should establish a periodic review and horizon-scanning process involving biosafety, synthetic biology, computational biology, public health, security and commercial experts [3-8].

The policy would also benefit from a capability-based horizon-scanning function to complement conventional event-based biosafety oversight. Existing systems ask whether a biological event has occurred. A capability-based approach would also ask what biological capabilities are becoming possible,

how accessible they are becoming and whether separate advances in AI, synthesis and automation are converging [9-11].

Relevant upstream signals may appear in scientific publications, preprints, patents, software repositories, synthesis services and cloud-laboratory platforms. The objective would not be to classify legitimate researchers or technologies as suspicious. It would be to identify changes in technological maturity, accessibility and convergence early enough for expert assessment, proportionate safeguards and preparedness measures.

The proposed NIH Biosafety Policy is a significant and necessary modernisation of the existing framework. Its principal strengths are the broader definition of biohazards, clearer institutional responsibilities, tiered oversight, standardised documentation and improved incident transparency.

Its principal limitation is that it remains centred largely on physical laboratory activities, while biological capability may increasingly develop across a digital-to-biological pathway. AI-generated biological designs, computational genome and protein engineering, DNA synthesis, cloud laboratories, automated biofoundries and remote experimentation may operate as connected components of this pathway.

NIH should therefore supplement the policy with explicit guidance on AI-enabled biological design, technology convergence, external providers, capability-based risk assessment and prospective registration of higher-risk AI-enabled biological research. The objective should not be to treat AI-enabled biology as inherently dangerous or to impede legitimate scientific innovation. It should be to identify changing biological capabilities early enough to assess dual-use implications, strengthen safeguards and support proportionate responses.

The policy should continue to ask what biological events are occurring, but the convergence of AI and biology also requires NIH to ask what biological capabilities are becoming possible, how accessible they are becoming and whether existing oversight mechanisms remain adequate.

Description: AI-Enabled Biological Design opinion piece and table summarising strengths and weaknesses of the current proposal changes.

AI-Enabled Biological Design: Why Biosecurity Surveillance Must Move Upstream

Authors: Ashley Quigley, Mohana Kunasekaran, Aye Moa, Abrar Ahmad Chughtai and C. Raina MacIntyre

Artificial intelligence (AI) is rapidly changing what is technically possible in biology. Among its most influential developments is generative artificial intelligence, a class of AI systems that learns patterns from existing data and human prompting to create novel content. Recently, research demonstrating that genome language models can generate novel viral genomes that, following synthesis and laboratory assembly, produce viable bacteriophages, provides an important example on how GenAI is expanding the frontiers of biological design and discovery. Sixteen AI-designed bacteriophages targeting Escherichia coli were experimentally demonstrated to be viable and biologically functional (1). These bacteriophages cannot infect humans and do not constitute an immediate human health threat. Their significance for biosecurity lies elsewhere: AI-generated biological designs have now been demonstrated to progress from computational outputs to functional biological systems.

This development illustrates an increasingly connected pathway between digital biological design and physical biological capability and raises an important question for health security: if biological capability increasingly begins in digital environments, are existing approaches to biological-threat surveillance looking in the right places, and early enough? Although this study was formally published in August 2026, it had been publicly available as a preprint on an online repository since September 2025, making it accessible to researchers for approximately 11 months prior to peer-reviewed publication (1,2).

AI is becoming part of the biological capability landscape

AI-enabled generative design is accelerating discovery across chemistry, biotechnology and synthetic biology. Machine-learning systems can generate novel molecules and biological sequences, with substantial potential benefits for medicine, biotechnology and other industries. Large-language models also reduce barriers to access by making highly technical and specialised information easier for non-experts or lay people to understand and use. Biological design tools, by contrast, may expand the capabilities of users with existing technical expertise, enabling more advanced biological design and optimisation. However, the same capabilities create dual-use research of concern (DURC) (3–6). In 2022, researchers demonstrated that a drug-discovery AI could be repurposed by changing its optimisation objective to generate approximately 40,000 potentially toxic compounds, including nerve-agent-like molecules (5).

The recent bacteriophage work extends this discussion from computational generation toward experimentally demonstrated biological function. Its importance is not simply that AI can generate viral sequences. Rather, it demonstrates multiple connected stages in a digital-to-biological pathway: AI can generate novel biological sequences that can subsequently undergo DNA synthesis and laboratory assembly, increasingly supported by automated or cloud-accessible laboratory infrastructure, before progressing to viable biological entities whose function can be experimentally demonstrated.

Important barriers remain. Substantial biological expertise and experimental validation are still required, and computational generation should not be conflated with the ability to produce a biological threat. However, the infrastructure barrier is also changing. Cloud-accessible and AI-native laboratories i.e. laboratories designed from the outset around AI, automation and robotics, rather than conventional laboratories that simply use AI as an additional analytical tool, are increasingly able to remotely coordinate specialised instruments and automate elements of experimental design, synthesis, execution and analysis (7,8). By outsourcing the operation and maintenance of specialised robotic instrumentation to remote providers, these platforms can reduce or eliminate the need for users to purchase costly equipment or be physically present in a laboratory (9,10). Cloud labs are also much harder to track or connect with individuals engaged in nefarious biodesign, as client data are private and not available on any registry. This transition is already evident in platforms such as Emerald Cloud Lab and Strateos (11,12), which enable researchers to design, execute and analyse experiments remotely using highly automated laboratory infrastructure, and in automated biological foundries such as Ginkgo Bioworks, that integrate computational biological design with high-throughput experimental workflows (8,13). These developments suggest that increasing integration of AI with automated and remotely accessible experimentation could rapidly narrow the practical gap between computational design and physical experimentation, with a corresponding increase in difficulty of monitoring such activity for biodefense.

This convergence matters because biological risk is shaped by the capabilities that emerge when technologies are combined. Over the past decade, AI applications in biology have evolved from analysing and predicting biological properties towards designing novel molecules, proteins and genomes, and increasingly connecting these computational designs with experimental systems capable of demonstrating biological function (Figure 1).

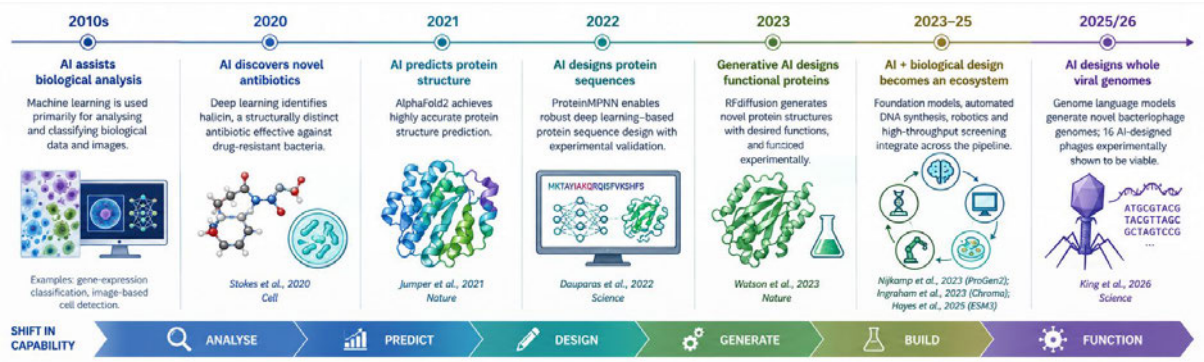

Figure 1. The Evolution of AI in Biological research: from prediction to functional biological systems: A timeline of selected milestones illustrating accelerating capabilities and expanding impact (1,14–20).

The biosecurity intelligence problem is changing

Traditional chemical and biological threat intelligence has relied substantially on physical indicators: acquisition of biological materials, specialist laboratories, unusual procurement, production

infrastructure and other observable activities. These remain important indicators. However, AI-enabled biological capability can begin much further upstream in digital environments and develop within legitimate scientific, academic and commercial ecosystems.

Event-based surveillance asks whether a biological event is occurring or has occurred. It seeks signals such as unusual disease, outbreaks, laboratory confirmation or evidence of deliberate release. Capability-based surveillance asks an earlier question: are the technological conditions that could enable future biological threats changing?

The two approaches are complementary. Conventional epidemiological and intelligence surveillance remains essential. However, as biological design becomes increasingly digital, an additional layer of surveillance may be required to identify upstream changes in technological capability while there is still time to assess their significance.

Relevant early signals may increasingly appear in scientific publications and preprints, patents, software repositories, technical reports and specialist discourse before conventional physical indicators become visible (21). Existing intelligence approaches are not necessarily designed to integrate these heterogeneous signals or assess how converging advances in generative AI, biological design, synthesis and automation collectively change biological capability (22–24). We therefore propose a distinction between event-based surveillance and capability-based surveillance. Surveillance should also capture upstream and downstream signals. Upstream signals could include sequence orders, cloud-laboratory use and protocol screening; downstream signals could include genetic signatures or mutations, with tools such as metagenomics used to flag novel pathogens.

Moving the surveillance window upstream and the role of open-source intelligence (OSINT)

Capability-based surveillance should not focus narrowly on identifying individual technologies as “threats.” AI-enabled biological design, DNA synthesis, synthetic biology and laboratory automation all have important legitimate applications. Their presence alone provides little information about malicious intent. Instead, the relevant unit of analysis may increasingly be technological convergence.

Potential indicators could include changes in the maturity and accessibility of biological foundation models; advances in AI-enabled molecular, protein or genome design; integration of generative models with synthetic-biology platforms; developments in DNA synthesis and laboratory automation; and evidence that previously separate technologies are becoming technically interoperable (25–27). Monitoring enabling technologies is particularly important because increasing feasibility may arise not from a single breakthrough, but from the progressive removal of barriers between design and implementation. This requires surveillance systems capable of identifying relationships among technologies rather than simply counting references to particular threats.

OSINT offers one mechanism for doing this. Scientific publications (including both peer reviewed and pre-prints), patents, software development and technical discourse provide observable information about technological development across geographically distributed research ecosystems. AI-enabled approaches, including natural-language processing and temporal trend analysis, may allow these information streams to be analysed systematically for changes in terminology, technological maturity and convergence.

There is precedent for using OSINT to complement conventional biological surveillance. AI-enabled epidemic early-warning approaches have demonstrated that open-source information can identify infectious-disease signals when conventional reporting is delayed or incomplete (28–30). OSINT has also been applied to health-security contexts outside conventional epidemic surveillance, including the detection of radiological events following the invasion of Ukraine (31).

The next challenge is whether similar principles can be applied further upstream, not simply to detect biological events, but to characterise changes in the technological environment from which future biological risks could emerge. Moving surveillance upstream also creates risks. The majority of AI-enabled biological research is undertaken for legitimate scientific, medical or commercial purposes. A publication describing a new biological model, an advance in DNA synthesis or the release of scientific software does not indicate malicious intent. Nor can OSINT alone establish intent. Capability-based surveillance must therefore avoid treating legitimate scientific innovation as inherently suspicious.

The objective should instead be to provide situational awareness of changing capability. Individual indicators would have limited meaning in isolation. Their value may emerge when multiple independent signals suggest increasing technological maturity, accessibility or convergence. This distinction should also inform governance. Safeguards applied to individual AI models may form one component of risk reduction, but such controls may be circumvented through techniques such as jailbreaking, or bypassed when models may be modified, fine-tuned or combined with other biological technologies. Findings from the GeneBreaker framework indicate that adversarial prompts may enable generative models to produce genome-like sequences resembling known pathogens, such as SARS-CoV-2 and HIV, with high levels of sequence homology (32). A Microsoft study showed that even with software patches, approximately 3% of biothreat designs still evaded the screening software used by DNA synthesis suppliers (33). It was also demonstrated how an AI-powered drug discovery tool could be used to generate blueprints for plausible novel toxic chemicals that could serve as chemical weapons (5). In an MIT study, a chatbot suggested four potential pandemic pathogens in a single hour and explained how they could be generated from synthetic DNA, supplied the names of DNA synthesis companies unlikely to screen orders and identified detailed protocols and how to troubleshoot them (34). Fine-tuning the Evo 2 model on 110 harmful human-infecting viruses rescued its ability to identify SARS-CoV-2 immune escape variants, demonstrating that pre-training data filtering is an insufficient safeguard (35).

Effective biosecurity will therefore increasingly require consideration of the wider technological ecosystem, including where meaningful barriers remain and where they may be eroding. Recent red-team testing of commercial nucleic acid synthesis demonstrated the importance of assessing safeguards at the system level: Edison and colleagues showed that individually unregulated DNA fragments could be obtained across multiple synthesis providers in combinations sufficient to circumvent existing controls, highlighting vulnerabilities that may not be apparent when individual transactions are considered in isolation (36). Such surveillance should support proportionate expert assessment rather than automated classification of research as benign or threatening. Its purpose is to help decision-makers recognise technological change early enough to consider whether additional assessment, safeguards or policy responses are warranted.

Existing research ethics and biosafety frameworks may not fully capture AI-enabled biological design at the stage where potentially consequential capabilities first emerge. Conventional oversight is generally triggered by research involving humans, biological materials, genetically modified organisms or physical experimentation, whereas AI-generated biological designs may initially exist entirely in silico. This creates a potential governance gap in which computational capabilities can develop before traditional ethical or regulatory oversight is engaged. Prospective registration of higher-risk AI-enabled biological design research could therefore provide an additional mechanism for transparency, accountability and early assessment of dual-use implications. The development of a prospective registry for AI-enabled biological design research, analogous in principle to clinical-trial registration. Research involving AI-generated, modified or optimised biological designs intended for physical synthesis or experimental validation could be registered prospectively, providing greater transparency around the transition from computational design to experimental biology. Such a registry could support responsible research norms and horizon scanning while avoiding disclosure of sensitive technical or proprietary information.

From detecting events to anticipating capability

The demonstration of viable AI-designed bacteriophages does not signal an imminent biological-weapons threat. It does, however, provide a timely illustration of why the relationship between digital biological design and physical biological capability deserves greater attention from the biosecurity community. As AI-enabled biological design converges with DNA synthesis, synthetic biology and laboratory automation, some of the earliest indicators of changing biological capability may increasingly appear in the digital scientific environment before traditional physical or epidemiological warning signals emerge.

Biosecurity surveillance should evolve accordingly. The objective is not to replace existing epidemic surveillance, laboratory systems or traditional intelligence approaches, but to complement them by moving part of the surveillance window upstream. Systematic monitoring of scientific, technological and open-source signals could help identify changes in biological capability while decision-makers still have an opportunity to assess risk, strengthen safeguards and prepare proportionate responses.

Biological-threat surveillance must continue to ask, ‘What biological events are occurring?’ But the convergence of AI and biology requires us to ask earlier: “What biological capabilities are becoming possible?” and “are bad actors intending to use or using these technologies?” Answering that question may be an important component of anticipatory biosecurity in the age of AI.

Strengths, Limitations and Emerging Biosecurity Gaps in the Draft NIH Biosafety Policy

Authors: Ashley Quigley, Mohana Kunasekaran, Aye Moa, Abrar Ahmad Chughtai and C. Raina MacIntyre

Area of proposed change	Strengths	Limitations and recommended improvements
Scope and definition of biohazards	Broadens oversight beyond recombinant and synthetic nucleic acid molecules to include wild-type biological agents, genetically modified organisms, toxins, prions and other self-aggregating proteins.	The proposed scope remains focused largely on physical laboratory research. It may therefore leave a gap where biological capability develops first in silico through AI-generated or AI-optimised sequences, proteins or genomes before synthesis or experimental validation occurs.
Institutional submissions and assurances	Provides a clear accountability structure and reduces repetitive reporting through a four-year assurance period.	Institutions may not have full visibility over work conducted through commercial synthesis providers, cloud laboratories, automated facilities or international partners. Because responsibility may be distributed across several organisations, the policy should clarify who is accountable for identifying and managing the associated biosafety and biosecurity risks.
Institutional Biosafety Committees	Maintains IBC oversight and requires institutions to keep current membership information, supporting local accountability.	IBC expertise may not always extend to genome-language models, computational protein design, AI-enabled dual-use risks, autonomous experimentation or biological foundries. NIH should provide guidance on accessing appropriate expertise in AI, synthetic biology, computational biology and biosecurity.
Tiered oversight and risk calibration	The distinction between NIH-level and institutional-level review is proportionate and should reduce unnecessary administrative burden for lower-risk research.	Risk assessment should not rely solely on Risk Group, BSL/ABSL or the physical agent involved. It should also consider what capability the research creates, how accessible that capability is, and whether several individually low-risk technologies are being combined
Risk Groups and BSL/ABSL classifications	Risk Groups remain useful for describing the inherent hazard of known agents. BSL and ABSL classifications remain essential for determining containment and operational controls.	These classifications do not by themselves capture the capability created through genetic modification, computational optimisation or technological convergence. NIH should retain them as foundational frameworks but add a project-level capability and modification assessment

Area of proposed change	Strengths	Limitations and recommended improvements
Lowering of containment	Provides clearer distinctions between NIH approval and IBC approval for lowering containment, particularly for RG2, RG3 and RG4 agents.	The policy should clarify how containment decisions apply to AI-designed or synthetic systems without an established Risk Group. Where the biological properties or consequences of a novel system are uncertain, the IBC should have a clear pathway to seek expert or NIH advice.
Delegated review	May improve efficiency for clearly defined lower-risk research and allow IBCs to focus on more complex projects.	It should not be used where novel AI-enabled designs, multiple converging technologies or substantial uncertainty make the risk difficult to characterise. NIH should specify exclusion criteria and escalation pathways.
Incident reporting	Standardised incident categories should improve consistency, institutional learning and NIH's ability to identify recurring problems.	The templates should also capture incidents occurring across the digital-to-biological pathway, including AI-enabled design errors, automated laboratory failures, cloud-laboratory incidents, synthesis-screening failures and incidents involving external providers.
Public reporting of incidents	Public-facing reporting can improve transparency and accountability.	Reports may expose personal information, commercially confidential information, sensitive pathogen information or operational details that could facilitate misuse. NIH should provide clear guidance on redaction, confidentiality and the distinction between publicly reported and confidentially submitted information.
Meeting-minute documentation	A standardised template should improve consistency and demonstrate that relevant risks were considered.	It should also allow IBCs to document uncertainty, dissenting views, conditions of approval, use of AI or external providers, technology convergence and reasons for referral to NIH or expert review.
Clinical research	Appropriately identifies higher-risk clinical research involving shedding, replication, integration, higher-risk manipulations and RG2 or higher wild-type agents.	AI-designed or AI-optimised products may not fit existing categories. Guidance is needed where computational optimisation changes biological properties or creates uncertainty about clinical risk.
Genetically modified plants	Excluding genetically modified plants and non-human-pathogenic plant pathogens may reduce unnecessary regulation of lower-risk plant research.	Plant, environmental and agricultural systems may still create ecological, food-security or economic risks. NIH should clarify how novel AI-designed plant pathogens and environmental systems interact with other oversight frameworks.
Commercial providers, cloud laboratories and	The institutional assurance model could encourage institutions to take	Biological capability may be distributed across researchers, synthesis companies, cloud laboratories and automated biofoundries. The

Area of proposed change	Strengths	Limitations and recommended improvements
Automated biofoundries	responsibility for research conducted through external providers.	policy should clarify provider disclosure, institutional responsibility and how oversight is maintained across these interfaces.
Voluntary compliance outside NIH funding	Could extend responsible biosafety and biosecurity practices to biotechnology companies, private institutions, commercial laboratories and other non-NIH organisations.	Participation may be limited if compliance creates administrative burden or punitive scrutiny. NIH should provide model policies, training, confidential consultation and recognition for voluntary alignment, while retaining mandatory requirements for clearly defined high-risk activities.
Prospective registration	A registry could support transparency, accountability and horizon scanning for higher-risk AI-enabled biological design research.	It could identify research involving AI-generated or AI-optimised designs intended for synthesis, assembly or experimental validation without requiring disclosure of sensitive sequences, proprietary methods or information that could create security risks.
Capability-based surveillance	Could complement event-based biosafety oversight by identifying emerging biological capabilities before an incident occurs.	As biological design becomes increasingly digital, NIH should also consider what capabilities are becoming possible, how accessible they are becoming, and whether separate advances in AI, synthesis and automation are converging. Relevant upstream signals may appear in publications, preprints, patents, software repositories, synthesis services and cloud-laboratory platforms.
Implementation guidance	Provides a foundation for modernising NIH biosafety oversight and standardising institutional practice.	NIH should publish worked examples and a decision tool covering AI-assisted analysis, AI-generated sequences, genome-language models, computational protein design, cloud laboratories, automated biofoundries and technology convergence. Guidance should distinguish routine AI-assisted analysis from AI-enabled biological design.
Future policy review	The framework can potentially be updated as biological research develops.	AI-enabled biology is developing rapidly, and static policy categories may become outdated. NIH should establish a periodic review and horizon-scanning process involving biosafety, synthetic biology, computational biology, public health, security and commercial experts. This would allow oversight to adapt as the barriers between digital design and physical biological experimentation change.

I am responding: On behalf of myself

Name: Ted Acott, PhD

Name of Organization: Oregon Health & Science University

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Glaucoma Biomedical Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We use human eye bank eyes for trabecular meshwork primary cell culture and for anterior segment organ culture. Occasionally, other portions of these eyes are also used for primary cell or organ culture, although this is not our primary focus. Research tissue is not screened by local eye banks for infectious agents, although transplantation tissue, which we seldom get is. We pay $1,335 for a pair of human eye bank eyes, normal or glaucomatous. In a single year, our group often pays $50,000 to as much as $100,000 just to obtain enough eye bank eyes to conduct statistically significant outcomes to our critically significant research questions. We do not do any animal research, only using human tissue. This is the best model for understanding human glaucoma and for working out treatments to translate to clinical glaucoma therapy. All of our work is thus basic science with the eventual goal of moving it to clinical glaucoma therapy. Since the eye bank does not screen this tissue for infectious agents, we presume that it is all contaminated with some nasty contagious infectious agents and treat all tissue with appropriate precautions. If this tissue became subjected to IBC review and if additional screening were required, who would pay the thousands of dollars this would cost? IBC and NIH would not, so this would likely shut down our several very key fully funded NIH?NEI research projects funded by NEI R01, R21, STTR and P30 grants. The fact that we are highly funded and I have been for over 44 years without any incidents suggest rather strongly that our work is of very high biomedical significance for developing much-needed glaucoma therapy. Since we do not get any specific donor information, we do not have to deal with human subjects requirements by NIH. That alone would require that we hire a person to handle that requirement and no one will pay for it so someone has to give up considerable research time to go through this process. Requiring IRB compliance for the many human eye bank eyes we buy every year would similarly take considerable time from our actual research to deal with the IRB compliance. If in addition, we had to go through extensive testing for infective agents, we would not be able to use the eye bank eyes within the short window of time that they are viable and would not be able to afford the testing for the many possible infective agents. This would kill our highly funded research projects to develop sourly needed new glaucoma therapies.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Additional oversight would be extremely detrimental to our glaucoma research NIH grants and would serve no function. We

are already treating this tissue as though it was dangerously infectious and this would serve no useful function and would devastate our very important research programs.

3. Continued utility of Risk Groups: We already use high risk BSL 2+ containment and biosafety for all tissue and extracts, so additional oversight would serve no purpose but would add another obstacle to our already very careful research progress.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): We already use very strong "voluntary" compliance for the safety of our employees and ourselves. Additional oversight would not improve this. We train all of our employees that have any contact to human tissue, directly or otherwise, to follow our strict safety policies.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We have never had any incidents, but would certainly report any if they occurred and take all precautions.

6. Other feedback relevant to this resource: Our research is already difficult enough and very expensive and human tissue is also quite expensive. Adding the burden of another layer of oversight and compliance to what we do now would serve no additional safety purpose and would encumber our research progress and add additional expense to our already very expensive tissue use. Human tissue is the best model for human glaucoma and we are already doing everything necessary to avoid any danger to our employees and ourselves.

357. Adelaide University

I am responding: On behalf of an organization

Name: Camilla Liddy

Name of Organization: Adelaide University

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Medical and scientific research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Policy should serve as a requirement for NIH-funded research, or institutions, where high-risk biological research is proposed (i.e. Select Agents, RG3 or RG4 microorganisms, or gene drive modified organisms) as these can pose risks of greater international significance. For lower risk research (RG2 and genetically modified RG2 organisms managed under an appropriate local framework) the NIH should recognise the provisions of the recipient's local jurisdiction and not impose additional requirements beyond providing a voluntary framework to fill any existing gaps in the recipient's local requirements.

The scope of the policy is very broad and is likely to be problematic in jurisdictions where there are competing regulatory requirements. Potential issues from an international perceptive include:

Regulatory incompatibility.

Australia has its own legislation (E.g. Commonwealth Gene Technology Act 2000) and standards (e.g. AS/NZS 2243.3) that align well with international equivalents and also take into account non-health related factors such as potential impacts on biosecurity and trade. Organisations needing to assess proposed research under multiple policies with different priorities and scope will lead to unnecessary complexity.

It is noted there is no allowance in the new policy for precedence (e.g., if there is conflict that local legislation/regulations will apply). The proposal for removing the absolute requirement for adherence to the new policy and replacing it with a registration process for international institutions operating under equivalent regulatory frameworks could address these in the global context.

For international institutions, such as those who are accredited by their Regulator or who otherwise operate within the local regulatory and compliance requirements, should be able to register their Institutional Biosafety Committees (IBC) with the NIH instead of being required to comply with the new policy. This approach is risk-proportionate, allowing institutions to operate within their own applicable

regulatory and compliance frameworks whilst enabling the NIH
to have oversight and awareness of this through the NIH governance process. This mirrors, for example, the approach taken for animal research, human research, and research integrity between international and US agencies. A part of the registration monitoring process could be regular reporting to the NIH to continue registration, and time limitations on the registration (again, similar to the arrangements for human research and animal research).

The intention of the policy to apply to all research regardless of funding source, which could interfere with contractual obligations to funders who, for example, require compliance with, in our case, Australian regulatory frameworks.

Composition and other administrative requirements for IBCs that are not aligned with the Australian context or regulatory expectations or requirements.
Significant administrative burden over and above the significant and appropriately calibrated administrative compliance and governance activities institutions already adhere to in order to satisfy complex and intersecting local regulatory and compliance requirements. This includes, but is not limited to, biosafety, general bio-compliance, and occupational health, safety and welfare legislation and regulatory requirements under Federal (national) and State/Territory legislation, regulations and standards.

Tension between the expectations of the new policy and local regulatory or institutional accreditation requirements have real potential for creating an environment for non-compliance, whether Inadvertently, unavoidably, or unintentionally, with the new policy, Australian legislation/regulations/standards/accreditation requirements, or contractual requirements (including funding rules, as may apply).

'GDMO' is not defined.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered approach is generally appropriate in a complicated regulatory environment such as biosafety. However as described elsewhere in our response, this new policy does not allow for integration with international regulatory frameworks and existing policy and procedural frameworks that comply with local regulations (in the Australian context these include Federal, State/Territory and National Standards requirements for both bio-compliance research and occupational health, safety and welfare). The requirements of the new policy are problematic to implement where the policy requirements conflict with local regulatory compliance or other requirements.

3. Continued utility of Risk Groups: Nomenclature in the Australian context is different and should be accounted for to enable ease of compliance. Noting that reducing the scope of research/organisations required to comply with the policy, or an equivalency arrangement (such as registration of international IBCs) could address this.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The Policy can serve as the basis for a voluntary compliance framework for research where there are gaps or uncertainties in the recipient organisation's

equivalent local biosafety frameworks. These appear to be appropriately captured, whilst not requiring adherence they encourage adoption of gold standards for all institutions conducting biosafety research.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The requirement to use these templates, especially where these are required for publicly accessible publication, is problematic where they interfere with minutes captured through compliance systems that have their own format of minutes, as is the case for Adelaide University for its IBC and health, safety and welfare aspects. Some flexibility in this approach to the format, whilst ensuring appropriate levels of information is captured in local formats, would be preferable.

6. Other feedback relevant to this resource: N/A

358. Mary Kelley, PhD

I am responding: On behalf of myself

Name: Mary Kelley, PhD

Name of Organization:

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): adult stem cells and glaucoma

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: This policy's scope would not be appropriate for the research performed in my lab. As glaucoma researchers, we already treat each pair of human eyes and corneal rims as potentially very hazardous, although they generally are not. All of our specimens are subjected to dissection in a laminar flow hood under sterile conditions, and our research personnel wear appropriate personal protective gear. We do not accept any eyes or corneal rims from the local eye bank known to be from patients who had been diagnosed with sepsis, HIV, or infectious diseases. If we do not receive these eyes or rims within 4-6 hours of death, they must be placed in culture immediately, or they will be unuseable for our research, as further testing would result in delays. The specimens are then placed in a typical laboratory incubator for cell or organ culture in flasks or 6-well plates for experimental procedures. All waste that touches the specimens, their media, or equipment is then either placed in a red hazardous bag tied tightly for incinerator disposal, instruments and beakers are sterilized with autoclaving or with bleach, and media is diluted with 20% bleach for half an hour or overnight. We clean the dedicated culture rooms thoroughly (P2 level only) and apply UV sterilization to the surfaces and room. We do not have live patients as a part of our experiments, so we are technically (by NIH) not considered to be human subjects research. I do not think that there is additional oversight needed for these purposes, as we maintain strict laboratory procedures to keep all personnel safe. Our eye bank eyes arrive in a special solution to keep them viable, and we never touch the specimens except with surgical tools in the hoods. These tools are then placed in a disinfecting tool sterilizing solution prior to autoclave treatment. If there were a potential danger to the public, then it would be valuable for NIH to know about it and put out a warning without naming researchers or their university, but there are such strict procedures in place with our lab and the university that it is a highly unlikely situation, especially with the type of research we are doing. Additional oversight would be quite expensive for our low risk area, as it would delay our work, mess up the timing and viability of our specimens, and result in much more expense not covered by the university or NIH. We already pay so much for human eye specimens as it is.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I do not see tiered oversight as being critical to the research we do with glaucoma, as our present system, where we are monitored by the university's IBC is quite appropriate and would increase the administrative burden

considerably. The risk is managed quite well by our university's IBC and our own self-monitoring. We are super cautious about working with tissues and cells, and keep the culture rooms' hoods and equipment in very highly maintained condition (laminar flow hoods checked professionally on a regular basis). We do not have additional time to devote to this, as we are already performing at a very high level of safety for our low risk experiments.

3. Continued utility of Risk Groups: We are at a lower risk level and are subject to procedures that nearly eliminate that as well. See above for more information considering safety.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Possibly these non-NIH funded institutions could set up an IBC group from other universities on a voluntary basis, with the incentives that this could be used on the IBC review researcher's CV as a positive attribute.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Protein aggregation is not well-defined in this policy, and many proteins aggregate. While it is true that something such as prion-research could be hazardous, still that does not mean it should not be done. Perhaps valuable health information may result from such research, although it should be limited to labs able to be at a higher biosafety level because of the higher risk. It probably already is restricted to that now anyway.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I strongly oppose the new policy. A modification that is not permanent or transferrable to offspring poses no threat to public or environmental health. As the RNA society stated "This re-classification could lead to confusion, misunderstanding, and loss of public trust in routine RNA research and in recombinant vaccine technologies, with potentially devastating public health outcomes."
This policy is a disservice to health sciences, and therefore life, as a whole.

Uploaded File: EBSA-NIH-response.docx

Description: Consultation response by the European Biosafety Association

EBSA Submission — Draft NIH Biosafety Policy for Research Involving Biohazards

EBSA welcomes the proposed Policy

The European Biosafety Association (EBSA) is the professional association for biosafety practitioners in Europe, and we welcome NIH's decision to modernise its oversight framework. We comment as an international stakeholder rather than as a funded party. For nearly fifty years the NIH Guidelines have operated as a *de facto* global reference; whatever replaces them will be read and copied internationally.

Our comments are therefore confined to points where a European perspective adds something NIH is unlikely to hear in volume from US respondents.

1. Recognise equivalent national oversight for research outside the United States

Section II applies the Policy to non-NIH-funded research at any institution receiving any NIH funding. For a European university holding a single NIH sub-award, this layers US institutional requirements onto work already regulated under Directive 2009/41/EC on the contained use of GMMs, Directive 2000/54/EC on biological agents at work, and national implementing regulations, typically with notification to or consent from a national competent authority.

Section II already allows research under another federal agency's purview to proceed under that agency's oversight. We suggest an analogous accommodation for non-US sites: where research is authorised by a national competent authority under an established statutory biosafety framework, that authorisation should be accepted as satisfying the Policy's containment determination, with the Assurance recording the framework relied upon. Absent such a provision, institutions face duplicated and occasionally conflicting determinations, and some will decline NIH funding rather than restructure their oversight. We would also note that six months from publication is a short transition where national authority processes must be realigned.

2. State IBC requirements functionally rather than structurally

Section III-B specifies the IBC by composition: at least five members, two unaffiliated with the institution, a BSO as a voting member for BSL-3/4 and GDMO work. European institutions generally discharge the same functions through differently constituted bodies, and the unaffiliated community member has no counterpart in most national frameworks; recruiting two is difficult for smaller institutions and awkward in some national contexts.

We suggest the Policy express these requirements as the competences and independence the review must demonstrate, allowing an institution to show how its existing committee meets them. The same applies to the BSO role, which in many European institutions sits with a biological safety adviser or research safety officer appointed under national occupational safety law.

3. Reconcile the publication requirements with data protection law

Mandatory public posting of IBC minutes and incident reports, retained for five years, is not straightforwardly lawful in the EU. Incident reports concern identifiable individuals and their health, which is special category data under Regulation (EU) 2016/679 (GDPR); publication requires a legal basis that a US funding condition does not supply. In an institution with one BSL-3 laboratory, de-identification is largely nominal.

We support the transparency objective. We suggest NIH state that the publication requirement applies subject to applicable national data protection and employment law, and issue redaction guidance alongside the templates, including a minimum content standard for a published report so that institutions are not left choosing between non-compliance and over-redaction.

4. The definition of genetic modification is broad

The Section II definition captures stable alterations introduced "by passaging, reassortment, chemical or radiological means". This is materially broader than the EU position, where Annex II of Directive 2009/41/EC excludes mutagenesis from the techniques treated as genetic modification for contained use.

The effect is to bring routine, long-established and generally low-risk microbiology into scope: serial passage, chemical mutagenesis, selection of resistant mutants. This sits awkwardly with the stated aim of removing red tape from low-risk research. We suggest either narrowing the definition or making clear in the implementation resources that such work ordinarily falls to delegated review under Section IV-3.

5. The National Biosafety Data and Safety Analysis Center should be opened internationally

The NBDSAC is, in our view, the most consequential proposal in the draft, and we support it without reservation. Non-punitive, de-identified reporting of near-misses and secondary failures is how aviation and healthcare built their safety evidence base. Biosafety has no equivalent anywhere, and incident data is scarce in every jurisdiction.

Two suggestions. The protection against enforcement use should be made as legally robust as can be arranged, since participation will collapse at the first instance of voluntarily submitted data being used adversely. And the Center should be designed from the outset to accept voluntary submissions from non-US institutions and to publish aggregate findings openly. EBSA would welcome the opportunity to contribute to that work and to connect it to European practice.

Closing

The draft Policy's ambition to serve as a model framework beyond the institutions NIH funds is well judged, and the points above are offered in support of that ambition rather than against it. EBSA would be glad to engage further as the Policy is finalised and the implementation resources are developed, particularly on international workability and on the design of the NBDSAC.

Submitted on behalf of the European Biosafety Association.

Pat G. Casey, President, European Biosafety Association; ebsa-office@ebsaweb.eu

361. Allyssa Baptista

I am responding: On behalf of myself

Name: Allyssa Baptista

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: • The scope and definitions in the draft policy require clarification. As written, the policy would be difficult for my institution to implement. Its scope should be clearly defined and focused on research typically conducted at BSL-2 or higher containment. Definitions of zoonotic agents, emerging agents, biological toxins, and self-aggregating proteins need clear criteria and examples of what is and is not covered.
• The expanded definition of genetic modification to include passaging, reassortment, and chemical/radiological means is too broad. It could encompass natural processes and would be extremely difficult for IBC's to interpret and register consistently.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): • Delegated review is a welcome addition, but it should streamline IBC review rather than expand it to include activities that should be outside the Policy's scope, such as work with established cell lines, transgenic organisms at ABSL-1, or genetic modifications and genetically modified organisms at BSL-1.
• A recurring theme throughout the NIH listening sessions was the need to reduce administrative burden and focus limited IBC and Biosafety Officer resources on higher risk projects or activities. The final section of the Draft Policy proposes a risk-based approach to assigning containment levels and risk-mitigation measures, which I support. However, other sections could increase administrative burden by requiring IBC's to review lower-risk activities and could significantly delay approval if institutions must petition NIH to assign containment levels for agents lacking a risk-group classification or recommended containment level in the BMBL.
• Allow IBCs to assign containment levels of BSL-2 and below using scientific literature and a risk-based assessment. Reserve NIH consultation for higher-risk agents requiring BSL-3 or higher containment, or for truly novel organisms that may require containment above BSL-2.

3. Continued utility of Risk Groups: • Risk Groups are distinct from Biosafety Levels. Risk Groups still give a general idea of the overall risk of the agent. If they a removed and replaced with Biosafety Levels, BSL would have to be redefined to include both risk levels and containment/risk mitigation methods. It might make things simpler for researchers to understand, but loses some of the nuance.
• The BMBL was never meant to be a regulatory document. It is a guidance document. It also focused

mainly on pathogens, so many non-pathogenic organisms are missing and lack both guidance on BSL and an assigned RG classification. These organisms should NOT require petitioning the NIH to assign biosafety levels if there is sufficient literature support to handle the organisms at BSL-1 or BSL-2. I would support having IBC's to do a risk assessment based on literature and location controls in this process.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: • Current incident-reporting and public-posting requirements could discourage members of the research community from reporting incidents because of concerns about sanctions such as loss of funding or reputational harm. Reduced reporting could undermine overall safety and inadvertently contribute to more serious incidents.
• Requiring IBCs to use the NIH template for meeting minutes, without flexibility to use institutional formats, would create significant administrative burden. The currently required level of detail is unlikely to meaningfully improve transparency or the effectiveness of IBC review.
• Provide templates for incident reports and IBC minutes as optional examples that institutions may adapt, rather than as required formats. Permit institutions to post redacted incident reports and meeting-minute summaries that provide adequate transparency while protecting confidential or sensitive identifying information.

6. Other feedback relevant to this resource: • Provide templates for incident reports and IBC minutes as optional examples that institutions may adapt, rather than as required formats. Permit institutions to post redacted incident reports and meeting-minute summaries that provide adequate transparency while protecting confidential or sensitive identifying information.
• Provide training materials and other implementation resources to help institutions meet the new requirements and inform their research communities about the revised processes.
• Consider convening a working group or expert panel that includes representatives of the biosafety, IBC, and research communities to review and revise the draft Policy.
• Provide an additional opportunity for public comment on the revised draft.
• Extend the implementation period to at least two years.

Uploaded File: NIH_Comment_AAB_10.19.26.docx

Description: Support letter and additional comments.

Subject: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Support for CSHEMA Recommendations

To Whom It May Concern:

I am submitting this comment in response to the National Institutes of Health (NIH) effort to modernize and strengthen the oversight of biosafety.

I support the comment submitted by the **Campus Safety, Health, and Environmental Management Association (CSHEMA)** regarding this effort. CSHEMA's comment appropriately reflects the needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

As an individual Biosafety Manager, my work would be directly impacted by a new NIH policy on biosafety and I support the recommendations outlined by CSHEMA.

Of particular concern are the following points:

- The scope and definitions in the draft policy require clarification. As written, the policy would be difficult for my institution to implement. Its scope should be clearly defined and focused on research typically conducted at BSL-2 or higher containment. Definitions of zoonotic agents, emerging agents, biological toxins, and self-aggregating proteins need clear criteria and examples of what is and is not covered.
- Delegated review is a welcome addition, but it should streamline IBC review rather than expand it to include activities that should be outside the Policy's scope, such as work with established cell lines, transgenic organisms at ABSL-1, or genetic modifications and genetically modified organisms at BSL-1.
- The expanded definition of genetic modification to include passaging, reassortment, and chemical/radiological means is too broad. It could encompass natural processes and would be extremely difficult for IBC's to interpret and register consistently.
- Current incident-reporting and public-posting requirements could discourage members of the research community from reporting incidents because of concerns about sanctions such as loss of funding or reputational harm. Reduced reporting could undermine overall safety and inadvertently contribute to more serious incidents.
- Requiring IBCs to use the NIH template for meeting minutes, without flexibility to use institutional formats, would create significant administrative burden. The currently required level of detail is unlikely to meaningfully improve transparency or the effectiveness of IBC review.
- A recurring theme throughout the NIH listening sessions was the need to reduce administrative burden and focus limited IBC and Biosafety Officer resources on higher risk projects or activities. The final section of the Draft Policy proposes a risk-based approach to assigning containment levels and risk-mitigation measures, which I support. However, other sections could increase administrative burden by requiring IBC's to review lower-risk activities and could significantly delay approval if institutions must petition NIH to assign containment levels for agents lacking a risk-group classification or recommended containment level in the BMBL.

- A six-month implementation period after publication of the final policy is not feasible. Institutions need sufficient time to understand the new requirements, identify gaps in existing registrations, update registration systems and processes, and train their research communities.

I feel the suggestions in CSHEMA comment do a good job at addressing these points. I would like to stress the following and add addition recommendations:

- Provide templates for incident reports and IBC minutes as optional examples that institutions may adapt, rather than as required formats. Permit institutions to post redacted incident reports and meeting-minute summaries that provide adequate transparency while protecting confidential or sensitive identifying information.
- Allow IBCs to assign containment levels of BSL-2 and below using scientific literature and a risk-based assessment. Reserve NIH consultation for higher-risk agents requiring BSL-3 or higher containment, or for truly novel organisms that may require containment above BSL-2.
- Consider convening a working group or expert panel that includes representatives of the biosafety, IBC, and research communities to review and revise the draft Policy.
- Provide an additional opportunity for public comment on the revised draft.
- Extend the implementation period to at least two years.
- Provide training materials and other implementation resources to help institutions meet the new requirements and inform their research communities about the revised processes.

Thank you for the opportunity to comment.

Sincerely,

Allyssa Baptista
Biosafety Manager
Littleton, MA

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I strongly support NIH's move toward a risk-based biosafety oversight model. This is an important improvement over requirements driven primarily by the type of biological agent or research methodology. However, the proposed Policy needs to recognize more fully the interdependence of human, animal, plant, and environmental health.

Human health cannot be separated from the biological systems that sustain human life. Animal and plant diseases can threaten food production, agricultural livelihoods, ecosystem stability, and food security, with substantial consequences for human health and well-being even when the causative agents do not directly infect humans. The absence of zoonotic potential does not mean the absence of human-health consequences.

The Policy's emphasis on known or potential risk to human health should therefore account for both direct and indirect consequences. This is particularly important for non-zoonotic animal pathogens, plant pathogens, and recombinant or genetically modified organisms that may alter virulence, host range, transmissibility, or environmental persistence without creating a directly infectious hazard to humans.

I recommend that NIH explicitly adopt a One Health framework that recognizes significant risks to human, animal, plant, agricultural, and environmental health. Oversight should remain proportionate to the likelihood and severity of credible consequences rather than extending formal review to every biological activity.

Where USDA, FDA, EPA, or another federal agency has relevant jurisdiction, NIH should coordinate oversight and recognize existing regulatory determinations where appropriate. A broader understanding of biological risk should not produce unnecessary duplication or additional administrative requirements for research that presents little meaningful risk.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support the introduction of risk-based delegated IBC review, but the Policy should more clearly distinguish

institutional accountability, IBC approval authority, BSO technical authority, principal investigator responsibility, and operational implementation.

A Biological Safety Officer should lead or administer the institutional biosafety program, provide competent technical advice, and have appropriate access to institutional leadership and escalation pathways. The BSO should not, however, be expected to personally conduct every inspection, investigation, training activity, or protocol review. The Policy should expressly permit qualified biosafety personnel to perform these functions under the designated BSO's authority and oversight.

Similarly, IBC oversight should not be confused with responsibility for managing institutional operations. Emergency response, facility maintenance, incident investigation, occupational health services, and corrective-action implementation may involve different responsible institutional units. The IBC should retain its defined review and approval functions without automatically becoming the operational owner of these activities.

The Policy should also recognize qualified institutional risk assessments and decisions made in good faith using established scientific guidance. NIH should identify which decisions require prior federal approval, which may be made institutionally, and the circumstances under which NIH may require additional measures. A documented institutional risk assessment should be a defensible basis for action unless superseded by applicable requirements or subsequent NIH determinations.

Finally, where another federal agency has jurisdiction over covered research, NIH should specify whether that agency's approval substitutes for NIH review, institutional IBC review, or both. These are distinct authorities and should not be treated as interchangeable.

3. Continued utility of Risk Groups: Risk Groups remain useful for initial biological hazard characterization, but they should not independently determine laboratory containment, IBC review category, or federal approval requirements.

Risk Group classification does not account adequately for the specific experimental procedures, agent concentration and volume, routes of exposure, animal models, available engineering controls, personnel susceptibility, or the biological characteristics introduced through genetic modification. These factors must be evaluated through an activity-specific risk assessment.

The Policy should distinguish agent hazard classification from the selection of containment practices and facilities. BSL and ABSL designations describe combinations of practices, equipment, and facility safeguards and are not interchangeable with Risk Group classifications.

NIH should also reconsider the requirement to petition for containment determinations for novel, emerging, or zoonotic agents when established guidance is unavailable. A lack of an agent-specific BMBL recommendation does not necessarily mean an institution lacks sufficient expertise or evidence to make a defensible containment determination.

I recommend that NIH establish clear criteria for when federal review is necessary, permit qualified institutional review where appropriate, and publish reusable containment determinations with their

scientific rationale. Institutions should not have to submit repeated petitions for comparable work when NIH has already established an applicable precedent.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed incident-reporting requirements need clearer thresholds that distinguish events with actual or credible potential biosafety consequences from routine operational deviations and equipment failures.

In high-containment facilities, an individual component failure does not necessarily constitute a loss of containment. Facilities employ layered engineering controls, operational procedures, and redundant systems specifically to prevent individual failures from resulting in exposure or environmental release. When the required containment function remains effective, failure of one component should not automatically trigger federal incident reporting.

NIH should define incident, exposure, release, breach of containment, and loss of containment, with examples distinguishing institutional documentation, IBC review, and mandatory NIH notification. These determinations should consider the hazard involved, actual or credible exposure potential, containment performance, and consequences rather than relying solely on the facility's BSL designation.

The Policy should also define when the 24-hour reporting period begins. An initial notification should require reasonably available facts, not a completed investigation or established root cause. Institutions should be able to revise preliminary classifications as additional evidence becomes available without penalty for a reasonable, good-faith initial determination.

I am particularly concerned about mandatory public disclosure of individual incident reports. Effective incident reporting depends on workers and investigators promptly disclosing mistakes, near misses, and unexpected events. Publishing identifiable information, preliminary findings, investigator names, and potentially sensitive facility or research details can discourage reporting and create privacy and biosecurity concerns.

NIH should distinguish complete regulatory reports from public-facing summaries. Public information should explain the event, its biosafety significance, the institutional response, and corrective actions without unnecessarily identifying personnel or disclosing sensitive operational information. Deidentified or aggregated reporting may provide greater value for preventing recurrence.

Finally, institutions subject to overlapping NIH, Federal Select Agent Program, or other reporting obligations should be permitted to rely on a common factual investigation and coordinated reporting process, while satisfying applicable program-specific requirements.

6. Other feedback relevant to this resource: The proposed Policy cannot be implemented consistently until NIH has issued the substantive guidance necessary for institutions to determine what compliance requires.

I recommend that NIH publish the final Policy together with authoritative implementation documents,

including risk-assessment criteria, containment guidance, incident-classification examples, reporting instructions, and clear definitions of institutional decision-making authority. These documents should distinguish mandatory requirements from recommended practices and identify when institutions may adopt equivalent risk-based controls.

In particular, the Policy should explicitly define the requirements for BSL-3 enhanced containment and associated occupational-health programs. Requirements currently contained in the NIH Guidelines should not be transferred into later guidance without clearly identifying which provisions remain mandatory, whether any have changed, and where authoritative requirements will reside.

The proposed six-month implementation period is insufficient if institutions must also revise their IBC procedures, training, information systems, incident-reporting workflows, public-disclosure processes, and existing research classifications. These changes require institutional coordination, resources, and, in some cases, new technical competencies or personnel.

The implementation period should begin only after all material requirements and supporting resources have been released. NIH should allow phased implementation where appropriate, establish predictable review timelines, and provide institutions with sufficient opportunity to assess their research portfolios and implement sustainable compliance programs.

NIH should also evaluate its own capacity to provide timely containment determinations, Assurance approvals, policy interpretations, and other required federal reviews. Institutions cannot meet compliance obligations that depend on NIH decisions unless those decisions can be obtained within predictable timeframes.

RE: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Dr. Bhattacharya,

On behalf of Hackensack Meridian *Health* (HMH), we thank you for the opportunity to comment on the National Institutes of Health (NIH) Draft Biosafety Policy for Research Involving Biohazards.[1]

HMH is the largest, most comprehensive, and truly integrated health care network in New Jersey, comprising a network of hospitals that includes three academic medical centers, one university teaching hospital, two children's hospitals, eight community hospitals, a behavioral health hospital, two rehabilitation hospitals and one long-term acute care hospital. Six of our 18 hospitals maintain robust academic medical programs. HMH also has more than 500 patient care locations, including ambulatory care centers, surgery centers, cancer centers, home health services, long-term care and assisted living communities, ambulance services, lifesaving air medical transportation, fitness and wellness centers, rehabilitation centers, urgent care centers, and physician practice locations. HMH has more than 40,000 team members and more than 7,000 physicians within its network and is a distinguished leader in health care philanthropy, committed to the health and well-being of the communities it serves.

As a national leader in clinical innovation and translational research, HMH has extensive experience conducting clinical trials involving advanced therapeutics, including gene and cell therapies. Operating at the intersection of clinical care and research, HMH brings direct experience implementing biosafety protocols in real-world care settings and offers a unique perspective on how federal biosafety requirements affect trial feasibility, patient access, and operational complexity.

Overview of HMH's Comments

HMH supports a modernized, risk-based biosafety framework that protects research personnel and communities, clearly delineates oversight responsibilities, and avoids unnecessary duplication. NIH should concentrate its oversight on preclinical biosafety standards and novel or higher-risk activities, while the Food and Drug Administration (FDA) remains the primary federal regulator of clinical research involving advanced biotechnology products. Appropriate institutional biosafety review should address risks arising from local handling and administration without repeating FDA product review or Institutional Review Board (IRB) review of human subject protections.

[1] https://grants.nih.gov/grants/guide/notice-files/NOT-OD-26-112.html

The final policy should translate these principles into clear scope boundaries, workable review categories, and coordinated implementation. Our recommendations below address the draft's scope, tiered oversight, risk assessment, compliance, and implementation resources.

Scope and Coordination of Clinical Research Oversight

With respect to Section II, ***HMH recommends that NIH clearly distinguish preclinical laboratory research, laboratory activities supporting clinical trials, and administration of investigational products in clinical settings.*** Biosafety assessment should focus on the settings in which products are prepared, handled, and administered and the procedures performed in those settings. The final policy should explain which activities in hospital pharmacies, infusion areas, specimen-processing facilities, and clinical laboratories are covered, and distinguish research from routine diagnostic testing and clinical care. Clear boundaries are especially important for health systems in which research and care occur in shared facilities.

Section II allows research under another federal agency's purview to proceed under that agency's oversight once applicable approvals or clearances are obtained. NIH should clarify how this provision interacts with the clinical research requirements in Section IV-2. For FDA-regulated trials, HMH recommends that FDA remain the primary federal regulator and that NIH-specific requirements be limited to distinct biosafety concerns not adequately addressed through existing federal and institutional processes. FDA oversight should not automatically eliminate necessary local biosafety assessment, but institutions should be able to rely on relevant FDA-reviewed and sponsor-provided information rather than recreate it.

HMH recommends that any IBC review of clinical trials focus on local exposure and containment risks, including product preparation, administration, shedding, and waste handling, rather than reassessing clinical benefit, product efficacy, or human subject protections. Although commercial IBCs have improved the separation of these functions, explicit NIH guidance would help institutions apply these boundaries consistently. NIH should provide an explicit division of responsibilities among FDA, IRBs, Institutional Biosafety Committees (IBCs), investigators, and clinical safety personnel so that necessary reviews can proceed in parallel without duplicating their respective functions.

Risk Based Categories and Streamlined Review

HMH supports the distinction in Section IV between research requiring NIH and IBC approval, research requiring IBC approval, and lower-risk research eligible for delegated review. Federal review should concentrate on activities for which material uncertainty or higher biosafety risk requires NIH expertise. NIH should publish clear criteria and examples for assigning research to each category and provide timely determinations when federal review is required.

For Section IV-2 clinical research, NIH should clarify how the triggers of shedding, replication, integration, and higher-risk manipulation translate into biosafety risk in the specific clinical activity. HMH recommends that the final policy distinguish risks to research personnel and the community from product characteristics primarily relevant to the treated participant. For example, assessment of a viral-vector investigational product should consider whether shedding could expose household or community contacts, based on the product's characteristics and available shedding data. The

presence of an integrating component, for example, should not by itself substitute for assessment of potential exposure, transmission, and the procedures performed at the site. This distinction would help avoid imposing the same review burden on products with substantially different biosafety profiles.

HMH supports delegated review under Section IV-3 for well-characterized, lower-risk research and minor amendments. NIH should clarify whether and when FDA-regulated clinical protocols with established safety experience may qualify for delegated review after an appropriate institutional assessment. Guidance should also distinguish amendments that change the biosafety assessment from administrative changes that can be documented without a new substantive review. These pathways should preserve IBC accountability and escalation when new information identifies additional risk.

For multicenter trials using the same product and protocol, NIH should allow institutions to use common sponsor biosafety documentation and shared assessments of product characteristics, supplemented by review of each site's facilities, personnel, and procedures. HMH uses an external IBC for many multicenter trials and its local IBC for preclinical research and certain clinical projects. NIH should clarify whether centralized or externally administered IBC arrangements can support this approach and what responsibilities remain with each participating institution.

Risk Assessment and Containment Decisions

In response to NIH's question on Risk Groups and Biosafety Levels, ***HMH recommends retaining Risk Groups as an initial reference while determining containment through an assessment of the actual agent or construct, proposed manipulations, potential exposure routes, and available safeguards.*** Risk Groups and Biosafety Levels serve different purposes and should inform one another. For genetically modified materials, the assessment should account for the effects of the modification rather than assume that the parent agent's characteristics fully describe the resulting material.

NIH should provide practical examples showing how institutions should evaluate attenuation, replication competence, integration, shedding, and administration procedures, as relevant. For viral-vector therapies studied in rare genetic disease trials, examples should explain how available shedding data and potential exposure routes inform precautions for household contacts after a participant leaves the clinical site. Such guidance would make decisions more consistent while preserving institutional judgment about local facilities and personnel. NIH should also provide a clear process for applying previously published containment determinations to materially comparable research.

Consistency Across Sectors and Proportionate Compliance

HMH encourages consistent biosafety expectations for substantially similar preclinical research across academic, health system, nonprofit, and commercial settings. Because NIH funding conditions do not reach every institution conducting comparable research, NIH should promote voluntary adoption through accessible guidance, model procedures, training, and coordination with other federal agencies. NIH should recognize equivalent protections provided by other applicable oversight frameworks rather than impose duplicative processes solely to achieve formal uniformity.

For institutions subject to the policy, Section II's application beyond individual NIH-funded projects makes clarity about institutional boundaries particularly important. NIH should explain how the requirements apply to affiliated hospitals, separately incorporated entities, sponsored research, and collaborating sites, and how responsibilities should be documented. Where multiple institutions participate in the same trial, NIH should allow documentation to focus on site-specific differences from the shared product and protocol assessment, rather than require each institution to repeat that assessment. Institutions should have clear notice of their obligations and a predictable process for addressing compliance concerns. Enforcement should be proportionate to the seriousness of the violation, associated risk, and corrective action taken.

Implementation Resources and Administrative Requirements

HMH recommends that NIH issue complete implementation guidance before the compliance period begins, including a decision tool for scope and review categories, examples for FDA-regulated clinical research, model delegation procedures, and instructions for coordinating institutional and sponsor documentation. NIH should provide a transition process for existing IBC approvals and ongoing studies, and ensure that institutions can obtain Biosafety Assurance approval without unnecessary interruption of research. The implementation schedule should reflect the time needed to inventory covered research, update procedures, and train personnel.

With respect to Section III-B and the draft reporting templates, NIH should allow institutions to use existing electronic systems and equivalent formats that capture all required information. The final guidance should clearly distinguish incidents requiring prompt NIH notification, lower-risk incidents requiring institutional review, and minor events that do not require reporting. Standardized examples would help institutions meet reporting expectations consistently without diverting attention from events with meaningful safety implications.

Public reporting should communicate the nature of the biosafety risk and corrective measures while protecting patient and employee privacy, confidential sponsor information, and security-sensitive details. HMH recommends clear redaction guidance and examples for clinical research settings, including circumstances in which combinations of otherwise non-identifying facts could reveal a participant's identity. NIH should also clarify the relationship between mandatory incident reporting and voluntary confidential reporting to the National Biosafety Data and Safety Analysis Center so that institutions can support safety learning while meeting their compliance obligations.

Conclusion

HMH appreciates NIH's consideration of our comments and looks forward to continued engagement on these important issues. If you have questions, please feel free to contact me at 201-370-8279 or Sarah.Lechner@hmhn.org.

Sincerely,

[redacted]

Description: NIH Biosafety Policy Comments

ADA Forsyth®

To Whom it May Concern,

The unification of oversight for all research involving biohazards, whether or not such research involves recombinant or synthetic nucleic acid technology, is a positive change and one that supports a more comprehensive and cohesive institutional biosafety program. The addition of a Delegated Review mechanism is another positive change, which reduces the burden on Institutional Biosafety Committees (IBCs), while providing institutions with the flexibility to define the Delegated Review process in a way that ensures appropriate oversight of lower-risk activities at individual institutions. We support these notable policy improvements.

While many aspects of the draft Policy represent improvements, there are several changes that are likely to have significant negative consequences, as well as points that would benefit from clarification. We respectfully submit the comments below for consideration to further improve the Policy.

1. New incident reporting requirements have an expanded scope of what counts as an incident in addition to the requirement to post all incident reports on a public website.

    a. **Impact:** These changes are expected to have a significant negative impact. The trust that biosafety programs have built up over the years in supporting researchers and encouraging people to report accidents will be eroded by fear of negative ramifications and/or retaliatory action. Even if reporting is anonymized and only a PI or supervisor name is included in the published report, there is a perceived risk of that information being used against the person, lab, and/or institution. People will be less likely to report accidents, which increases the risks associated with untreated injuries or exposures to hazardous materials.

    b. **Recommendation 1**: Individual incident reports should not be publicly posted. Reporting should be to NIH, where data on incidents can be aggregated and trends analyzed and/or reported in a way that removes institutional affiliation to further anonymize individuals involved in an incident. That allows for analysis of the data and identification of trends, which would be a valuable resource to the community, while avoiding negative consequences on the individual, lab, or institution, which would, in turn, undermine the value of the incident reporting process.

    c. **Recommendation 2**: If institutions must be required to publicly post incident information, allow an aggregated annual report. Such an approach could be modeled after OSHA's Form 300A (Summary of Work-Related Injuries and Illnesses). We would

strongly recommend this approach for incidents defined by this Policy, which would not be reported to NIH but would be reported to the IBC.

2. The draft Policy states that IBC approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required. It further lists failure to maintain IBC approval as a reportable incident.

    a. **Impact:** The expected impacts of these changes are a significantly increased administrative burden and unintentional non-compliance. In the absence of a specified term limit, many institutions adopted internal policies that require IBC approval to be renewed within a 5-year period, which also coincides with the length of many grants supporting the approved research activities. Switching to a shorter 3-year renewal cycle presents a significant increase in committee workload. Additionally, well-intentioned PIs may face unexpected emergencies, or their registration renewal may come at a time when they are burdened with high workloads from teaching and/or other institutional responsibilities. Because there is no mechanism described in the draft Policy for allowing extensions to PIs facing extenuating circumstances, failure to renew an IBC registration on time would result in a reportable incident of non-compliance.

    b. **Recommendation 1:** Keep a defined term limit on IBC approval but increase the term of IBC approval to 5 years.

    c. **Recommendation 2:** Empower IBCs to exercise judgement and flexibility in granting reasonable, one-time extensions to PIs facing extenuating circumstances and/or moving a registration renewal to a different time of year so as not to conflict with other high-workload periods.

3. The draft Policy states that research with primary cells that may be contaminated by adventitious agents requires IBC review and approval under Section IV-2. We interpret this new scope to mean that any primary human cell line, tissue, or clinical specimen with an unknown status (has not been tested for bloodborne pathogens or other infectious agents) will have to go to the IBC for approval, whereas none of this material required IBC review previously. Instead, this material fell under the OSHA Bloodborne Pathogens Standard, which requires institutions to establish oversight mechanisms that have worked for many decades.

    a. **Impact**: This change is expected to have a significant negative impact. The increased burden on most IBCs will be enormous, with no apparent benefit, since the existing mechanisms to comply with the OSHA Bloodborne Pathogens Standard must still be

maintained. This is an unnecessary duplication of oversight, and the increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

b. **Recommendation**: Allow this type of material to be approved via the new Delegated Review process described in Section IV-3 rather than requiring IBC review. That would allow institutions flexibility to integrate existing biosafety oversight mechanisms into the Delegated Review process defined by the new Policy.

4. The draft Policy states that research involving genetically modified cells, viruses, or organisms, other than plants requires IBC approval and approval under Section IV-2. Previously, a large portion of genetically modified cell lines were considered exempt under Section III-F-8, Appendix C-I. For many IBCs, that type of material made up the majority of genetically modified material, and because it was considered exempt and did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely and in accordance with the OSHA Bloodborne Pathogens Standard. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8, Appendix C-I now falls under Section IV-2 and requires full committee review.

   a. **Impact**: This change is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because the main risk associated with material that fell under Section III-F-8, Appendix C-I was the risk of adventitious agents or bloodborne pathogens, as mentioned in point 3 above. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

   b. **Recommendation**: Retain the Section III-F-8, Appendix C-I exemption, or allow materials that would have fallen under Section III-F-8, Appendix C-I to be approved via the Delegated Review process described in Section IV-3.

5. The draft Policy's definition of a genetic modification includes introduction into cells, organisms, or viruses of stable alterations into the genome by passaging. It is not clear what passaging activity falls within the Policy scope. Simply culturing an organism in vitro will lead to accumulation of undefined genetic alterations and could be considered passaging. Cultures that are maintained in a lab are also considered to be passaged through the process of sub-culturing to create multiple stocks from an original sample. Further, most of the time, growing an organism in vitro or in a model system selects for mutations that optimize growth in a lab environment, not in a human host, and these lab-adapted strains typically lose virulence or pathogenicity. The Influenza A/Puerto Rico/8/1934 (H1N1) strain (often called PR8 influenza) is

a classic, mouse-adapted laboratory strain of the influenza A virus isolated from a human patient in Puerto Rico in 1934. It is an example of a strain that is a lower risk option for studying influenza. These examples of passaging generally have not required IBC review. In the draft Policy, all of these activities would require IBC review and approval under Section IV-2 (see also point 4 above).

   a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because most passaging does not increase the risk of the agent or associated research activities. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

   b. **Recommendation**: We recommend refining the scope of the definition of genetic modifications by defining passaging as the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile. Examples of passaging activities that should be included in Section IV-2 include passaging with the intent or likelihood for an agent to acquire a new virulence trait or antibiotic resistance or to adapt a pathogen to a new host species and/or tissue tropism.

6. In the draft Policy, the definition of genetic modification that falls within the scope of the policy now includes modification via chemical or radiological means. Further, the draft Policy requires the IBC to review all genetically modified cells under Section IV-2 (see also point 4 above). The main risk associated with use of chemical or radiological agents to create mutations is in the handling of the chemical or radiological material, not necessarily in handling the cells once the mutagen has been removed. There are separate regulations that apply to chemical and radiological hazards. The use of chemical and radiological hazards is best handled by the respective safety experts who are familiar with the appropriate regulations and safety requirements, not the IBC. Assessment of the risks of these mutagens are outside of the scope of an IBC, since IBC members typically have little to no expertise on chemical or radiological hazards.

   a. **Impact**: This is a vast expansion of scope that will duplicate oversight and increase burden on IBCs, without a clear benefit. Further, the IBCs typically lack appropriate expertise for evaluating the risks associated with these mutagens. The increased burden on IBCs will detract attention from higher-risk matters, which do fall within the expertise of the committee.

b. **Recommendation**: Remove chemical and radiological means from the definition of genetic modifications that fall within the scope of the policy and defer oversight to existing regulations that apply to the use of chemical and radiological hazards. Alternatively, refine the scope to apply to experiments in which the mutagenic agent is combined with the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile, as recommended for passaging in point 5 above.

7. The draft policy states that research with genetically modified RG1 biological agents requires Delegated Review under Section IV-3. Previously, most standard cloning and/or protein expression with *E. coli* and other model host-vector systems were considered exempt under Section III-F-8, and it did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely with proper waste disposal procedures. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8 now requires Delegated Review.

    a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. The increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

    b. **Recommendation 1**: We strongly recommend retaining existing III-F-1 through III-F-8 exemptions.

    c. **Recommendation 2**: Furthermore, and supported by decades of safe research experience, we also recommend expanding the exemptions to include other low-risk cloning and protein expression research in model organisms such as *E. coli* BL21 strains, *C. elegans*, and *Drosophila*.

8. The draft Policy states that research conducted with transgenic organisms at BSL-1/ABSL-1" requires Delegated Review. Previously, almost all breeding or purchasing of transgenic rodents was exempt under Section III-F-8, Appendix C-VII and was not typically registered with an IBC at all. Instead, oversight of those transgenic rodents typically has been handled through federally mandated Institutional Animal Care and Use Committees (IACUCs) that have biosafety professionals as members who conduct risk assessments and suggest risk mitigation measures as part of that review process. Many IBCs do not even have a mechanism for tracking this information. Additionally, many researchers using transgenic mice are not using any other sort of biological material; the research is often focused on behavioral studies or pre-clinical studies

that fall outside the scope of an IBC. A very large proportion of transgenic animal work is done with transgenic rodents and zebrafish, and almost all of that work poses no new risk compared to the unmodified rodents and zebrafish.

a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. Again, the increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

b. **Recommendation 1**: We strongly recommend retaining the III-F-8, Appendix C-VII exemption and allow existing oversight of these low-risk animals to continue via the IACUC.

c. **Recommendation 2**: As mentioned in point 7 above, we also recommend expanding the exemptions to include other low-risk transgenic model organisms such as zebrafish, *C. elegans* and *Drosophila*.

9. The draft Policy defines biological agents that fall within the scope as bacteria, viruses, fungi, or parasites that cause human disease. This definition seems to contradict the draft Policy's requirement for Delegated Review of research with genetically modified RG1 biological agents (see point 7 above). Risk Group 1 agents are <u>not</u> associated with disease in healthy adult humans. Some agents may be considered opportunistic pathogens, but there is currently no list of RG1 organisms that are considered opportunistic pathogens.

    a. **Recommendation 1:** NIH should clarify the nature of biological agents that fall within the scope of the Policy. We recommend that the Policy scope is limited to pathogenic biological agents that cause disease in humans, including opportunistic pathogens but <u>excluding</u> non-pathogenic agents.

    b. **Recommendation 2**: As there is no list of RG1 agents, and the list of RG2 agents is incomplete, we further recommend empowering the IBCs, Biosafety programs, and PIs to make the determination of RG1 and RG2 for biological agents that are not currently listed in Appendix B of the NIH Guidelines or the BMBL using the risk assessment guidance provided therein.

10. The draft Policy's definition of a genetic modification includes introduction of materials that can be transcribed or translated. This would include materials such as purified or synthetic miRNAs, snRNAs, shRNAs, and mRNAs, which are transient in nature and may lead to changes in gene expression but do not replicate and do not modify or integrate into the genome. Work with

such materials was previously exempted under III-F-1 but would now fall under Section IV-2 and require IBC review and approval.

a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create a significant new burden on IBCs, with no apparent benefit given that no genetic modifications are made with these materials. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

b. **Recommendation:** We recommend retaining the III-F-1 exemption and removing these materials from the scope of the Policy.

11. The scope of the draft Policy includes prions and self-aggregating proteins, and research activities involving these materials would require IBC review and approval. We support the draft Policy as it pertains to prions, but request refinement of the oversight pertaining to self-aggregating proteins. IBC oversight should not extend automatically to every protein capable of self-aggregation. Protein aggregation is common in biology and, by itself, does not establish an infectious or exposure hazard. Oversight should instead focus on proteins or protein assemblies for which there is credible evidence that an aggregated conformer can act as a persistent, self-propagating seed; induce conformational conversion of the corresponding native protein; spread between cells or tissues; and transmit pathology following experimental exposure or inoculation. We recommend the following risk-assessment approach, which is consistent with the BMBL principle that containment decisions should be protocol-driven rather than based only on an agent's name.

a. **Recommendation 1:** Classical mammalian prions and prion-containing tissues should remain categorically within IBC purview because of their established infectivity, potential for serious disease, environmental persistence, and resistance to conventional inactivation procedures.

b. **Recommendation 2:** Seed-competent aggregates of α-synuclein, including preformed fibrils, amplified seeds, and α-synuclein-containing material derived from affected human or animal tissue, should also be subject to IBC review because α-synuclein assemblies have demonstrated prion-like templating, cellular and anatomical propagation, and experimental transmissibility in animal models. Inclusion under IBC oversight should not be understood to mean that α-synuclein is known to be naturally communicable between people or that it presents the same level of hazard as a classical prion.

c. **Recommendation 3:** Other self-aggregating proteins should be evaluated individually rather than be included in Section IV-2 of the draft Policy solely because they form oligomers, fibrils, or amyloid. Relevant considerations should include evidence of experimentally transmissible pathology, persistence of seeding activity, resistance to standard decontamination, source and concentration of the material, route and scale of exposure, use of human- or animal-derived pathological tissue, and procedures involving inoculation, sharps, aerosols, or other opportunities for occupational exposure. Routine work with non-seed-competent monomeric proteins or aggregates lacking evidence of biological propagation would not ordinarily require specialized biosafety review beyond the requirements otherwise applicable to the experimental system, and we recommend that the Delegated Review mechanism described in Section IV-3 be applied to such work.

12. The scope of the draft Policy includes toxins listed as Select Agents, and research activities involving these materials would require IBC review and approval under Section IV-2, while research with biological toxin proteins not on the Select Agent list may be approved by Delegated Review under Section IV-3. We support this overall approach; however, we request refinement of the Policy with the following recommendations.

    a. **Recommendation 1:** Allow research activities using exempt amounts of Select Agent toxins to be approved by Delegated Review. Most institutions have already developed effective internal biosafety oversight mechanisms for handling these exempted materials. Integrating those internal oversight mechanisms into the Delegated Review process would allow IBCs to focus on the higher-risk Select Agent work.

    b. **Recommendation 2:** Either publish a list of biological toxins that fall within the scope of the Policy or use a threshold toxicity value as a risk-based factor for determining whether a biological toxin requires oversight by the Policy. We further recommend that biological toxins that have an LD_{50} greater than 1000 µg/kg be exempt from this Policy.

13. The scope of the draft Policy includes cells, viruses, or organisms, other than plants, that have been genetically modified. It is assumed that animals are included as organisms, but it is not clear what is considered an animal under this Policy.

    a. **Recommendation:** Use a definition of animal that is consistent with the Guide for the Care and Use of Laboratory Animals, which has been adopted by the NIH Office of Laboratory Animal Welfare, and which defines animals as any vertebrate animal (i.e., traditional laboratory animals, agricultural animals, wildlife, and aquatic species) produced for or used in research, testing, or teaching.

14. The draft Policy indicates that the effective date will be 6 months from publication of final Policy, and that applicability includes ongoing work. It is unclear how ongoing work will be impacted by the new review and approval requirements. Work that was not subject to IBC oversight according to the NIH Guidelines may have been approved via voluntary institutional biosafety oversight mechanisms.

    a. **Impact:** Work that was approved by a Biosafety Officer (or other institutional biosafety oversight) and now requires a higher level of review by the IBC would need to cease until IBC approval is obtained. This would have a significant negative impact on a large number of projects that are suddenly subject to new oversight, thereby wasting grant money and setting back important research projects.

    b. **Recommendation:** Require activities that have not received approval by a Biosafety Officer or other institutional biosafety oversight mechanism to be reviewed and approved according to the final Policy within 6 months of the publication of the final Policy. For activities that have received approval by a Biosafety Officer or other institutional biosafety oversight mechanism, allow the existing approval to remain in place until such time as de novo registration is required (see point 2 regarding our recommendation to allow 5-year term limits for IBC registration approvals).

Respectfully Submitted,

Xuesong He, PhD, DDS

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious Diseases and HIV Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We appreciate that the new policy expands to include emerging threats like synthetic biology. However, we believe the second inclusion to the policy's scope, "Cells, viruses, or organisms, other than plants, that have been genetically modified," should be further narrowed considering the policy encompasses all biomedical research in all laboratories. This is a very broad definition that could end up including incredibly basic research without dual use or major biosafety concerns. We recommend narrowing this definition – one possible option would be refining the language to target research of concern, such as: "Cells, viruses, or organisms, other than plants, that have been genetically modified to enhance an existing quality, add a novel quality, or increase transmissibility of the cell, virus, or organism."

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): We agree with NIH's intent for this policy to apply to all NIH-funded research and institutions involving moderate- or high-concern biohazards. Biosafety practices must be enforced at both the federal and local levels. However, we stress that NIH must be sure it is able to have an adequate workforce to ensure compliance work within the agency to ensure the institutions and research at the local level are complying with the policy. This policy will entail increased enforcement at both the federal and local/institutional levels, especially for research under Section IV-1, "Research That Requires NIH and IBC Approval Before Initiation," which will mean an increase in administrative work for approval, review and oversight processes. Any additional funding from NIH that could be provided to institutions to support the needed staffing for oversight and review capacity would help incentivize compliance at federally funded institutions.

3. Continued utility of Risk Groups: We agree with the continued use of the risk groups as a baseline – however, we do believe some of the definitions should be modified to make the lower-tier risk groups less broad. As it stands, the language in Section IV-2 for research "requiring full Institutional Biosafety Committee (IBC) review and approval before initiation" would expand and make many basic laboratory protocols with non-modified bacteria require institutional IBC protocol approvals, which would likely require months of wait time based on the backlog that currently exists at many institutions. For example, one specific provision includes "research involving genetically modified cells, viruses, or organisms, other

than plants." This represents a massive array of experiments and protocols that would require approval, despite the definition being so broad that many non-hazardous experiments would fall within this category. Expanding the definitions unduly to include research with low concern will only increase IBC backlogs, delay research and make it impossible to finish within defined timelines. We recommend narrowing this specific section of the policy in line with other language under Section IV-2 that specifically highlights research with reasonable hazards.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Clear, consistent, non-punitive guidance and materials from NIH will help ensure that non-NIH funded institutions still work with NIH on their biosafety policies. Many institutions do not have the staff to do consistent additional administrative work, including on biosafety reporting and review – anything that NIH can provide these institutions as templates or guidelines to help streamline that work would likely accommodate voluntary compliance.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Liquid Biological Waste Treatment with sodium Hypochlorite

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Yes, continue to use RG as a baseline for risk assessments.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Recommendation: Establish Standardized Sodium Hypochlorite Concentrations for Liquid Biological Waste Disinfection

Proposed Action

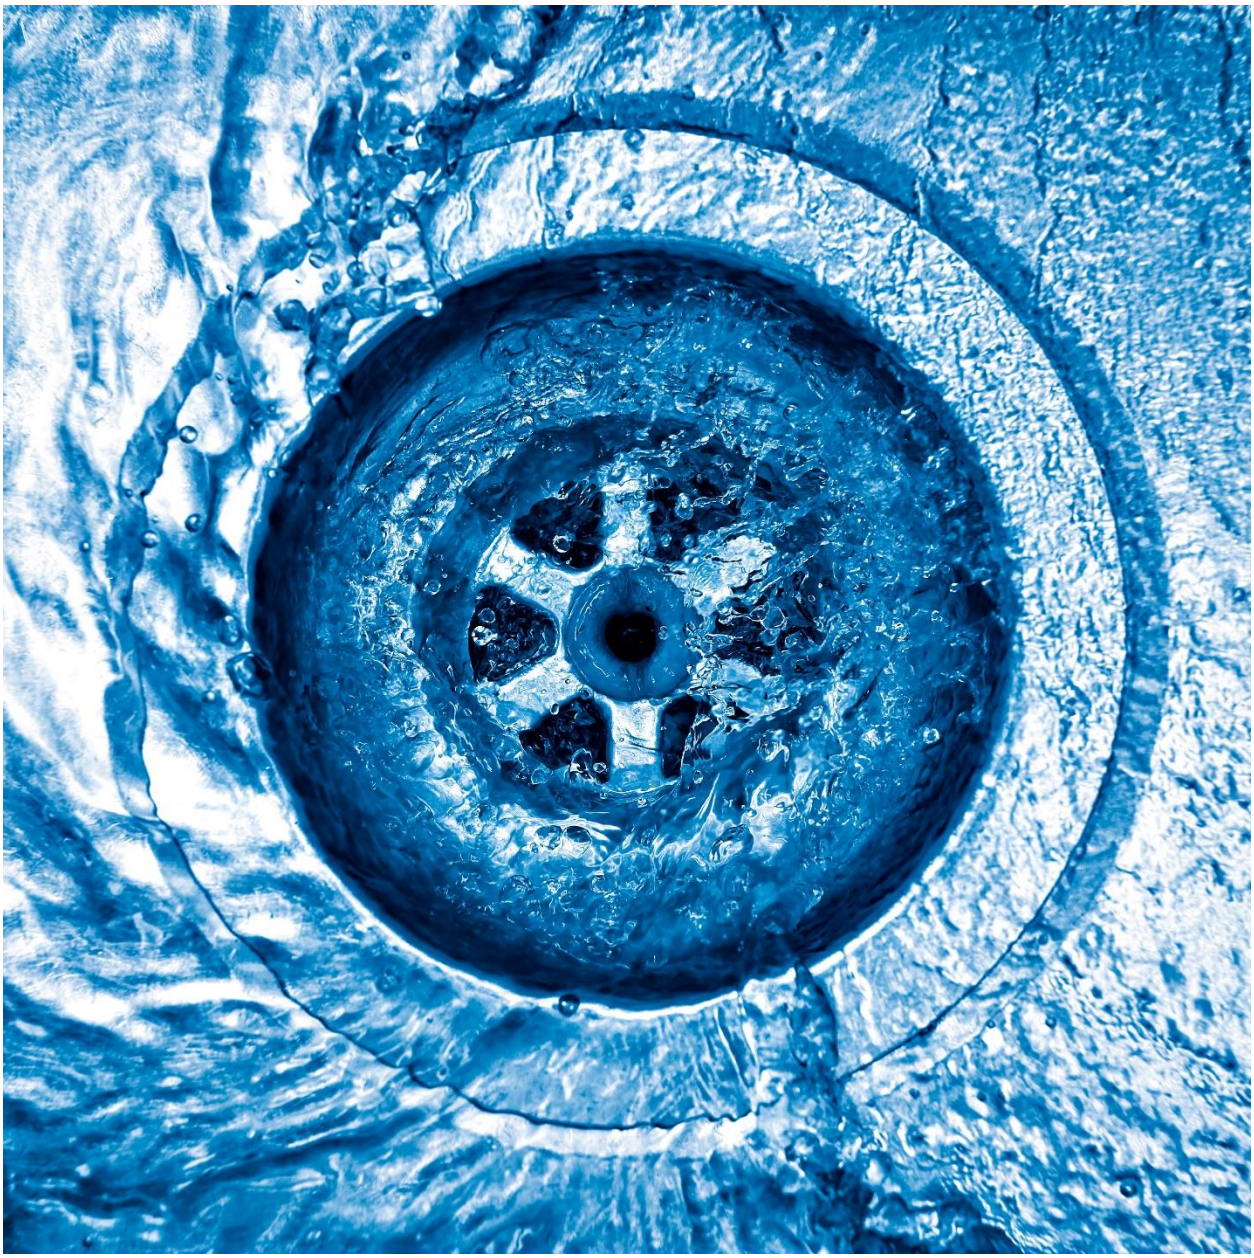
The NIH should provide specific, standardized concentrations of sodium hypochlorite (bleach) and contact times for the disinfection of Risk Group 1 (RG1) and Risk Group 2 (RG2) liquid biological waste (LBW). Specifically, the NIH should adopt and publish clear, baseline guidance such as:
• 5,000 ppm free chlorine for 20 minutes when minimal or no organic materials are present.
• 10,000 ppm free chlorine for 30 minutes when significant organic materials are present.

Justification and Problem Statement

Currently, institutions face regulatory and practical gaps when determining liquid waste treatment protocols:

• Testing is Impractical: Expecting individual research institutions to conduct independent efficacy testing for every unique RG1 or RG2 biological agent in liquid solution is logistically impractical, cost-prohibitive, and contrary to standard institutional practices.
• EPA Registration Gap: While the US EPA registers disinfectants, these approvals are almost exclusively validated for hard, non-porous surfaces, leaving a regulatory vacuum for the treatment of bulk liquids.
• Standardized Consensus Exists: Literature reviews and AI-assisted data aggregation show that 5,000 ppm and 10,000 ppm are already the most widely accepted and empirically cited benchmarks for safely inactivating RG1 and RG2 waste when no chemically incompatible agents are present.

Benefits of Implementation



Implementing this standardized guidance will provide significant advantages across the research community:
• Enhanced Biosafety Compliance: Clear, authoritative benchmarks from the NIH eliminate guesswork, ensuring that institutions consistently achieve complete pathogen inactivation.
• Increased Operational Efficiency: Eliminating the perceived or literal requirement for individual validation testing saves institutions hundreds of hours in administrative and laboratory labor.
• Standardized Oversight: Institutional Biosafety Committees (IBCs) and biosafety officers will have a concrete, NIH-validated metric to reference during protocols reviews and facility audits.
• Reduction in Environmental/Safety Risks: Providing exact numbers prevents the common issue of over-bleaching (which creates unnecessary toxic vapors and hazardous chemical waste) or under-bleaching (which risks environmental release of viable pathogens).

APPENDIX B – EXPANDED LIST OF CHEMICAL SOLUTIONS APPROVED FOR DRAIN DISPOSAL 9

OVERVIEW

The National Institutes of Health (NIH) is made up of 27 Institutes and Centers, each with a specific research agenda, focusing on diseases or body system. The NIH has over 3000 labs on the Bethesda campus, including local off-campus and regional facilities, where biomedical research is conducted including animal facilities, clinical and patient care areas and industrial activities. These activities produce an array of waste both hazardous and nonhazardous which must be managed appropriately. This document provides guidance based on policy, permits, and regulations, for materials which must be collected for proper disposal and a select group of chemicals which can be discharged under specific conditions. The NIH objective is to dispose of chemicals via the waste management service and limit discharges to the sanitary sewer. Current NIH waste management practices include collection of chemicals through waste disposal services. **Only chemicals pre-approved for drain disposal** may be disposed of down the drain (see page 3). All other chemical waste should be managed and disposed of as chemical waste according to the instructions on page 3 of this guide. The NIH will review policies, regulations and procedures, and update this guide on a periodic basis.

WASTE POLICY

The NIH waste policy requires that all wastes be reduced to the greatest extent feasible to limit any negative environmental impact. Proper management of all wastes, including their characterization, collection, labeling, packaging, storage, recycling, transportation, treatment and final disposal, is also required. Disposal of chemical wastes, including pharmaceutical wastes, via the sanitary sewer is regulated by federal, state and local laws and regulations. Violation of these regulations may result in citations for non-compliance from local, state or federal authorities.

Per EPA regulations, wastes are considered hazardous if they exhibit any of the following characteristics: ignitability, corrosivity, reactivity, and toxicity; or if they are specifically named on one of four lists of hazardous wastes in the Code of Federal Regulations (40 CFR). Additional state and local laws and regulations also apply respectively to waste generated in NIH facilities. These regulations and restrictions must be adhered to by all NIH personnel, contractors and/or anyone involved with the generation of wastes or waste management and support services at all NIH facilities, including but not limited to the Bethesda main campus, local off-campus facilities (Baltimore, Frederick, Poolesville and Rockville) and regional facilities (Montana and North Carolina).

CHEMICALS APPROVED FOR DRAIN DISPOSAL

It is the responsibility of each NIH laboratory worker to ensure that chemical waste generated from their activities is disposed of properly. Chemicals put down the drain may interfere with the process of removing contaminants from Publicly Owned Treatment Works (POTW). After treated waste water leaves the POTW, it flows to major recreational and drinking water resources in our areas. The stewardship of these important natural resources is our collective responsibility.

Laboratory workers should consult this guide before undertaking drain disposal of any lab chemicals. **Only chemical approved for drain disposal** by the NIH Division of Environmental Protection (NIH/DEP) may be disposed of down the drain. **Surplus solid chemicals must be disposed of through the NIH chemical waste services and not discharged down the sanitary sewer**. Below is the approved chemicals list. Click A – Z to expand the list for approved chemicals or see the Expanded List at the end of this Guide (see Appendix B).
Chemicals that are not listed below must be managed as chemical waste and collected by your IC's chemical waste service for disposal (see Appendix A). Dilution to achieve compliance is prohibited per EPA CFR Dilution Prohibition.

When disposing of approved chemical via the drain use the following procedure:

1. *Ensure the sink to be used for drain disposal of chemicals is clear of all items.*
2. *The worker shall wear appropriate PPE (lab coat, nitrile gloves, and protective eye wear).*
3. *Turn on cold water and let run for about one (1) minute to ensure there is adequate flow of water down drain, no back up into the sink. Do not use the sink for disposal of chemicals if water does not freely flow down the drain.*
4. *Slowly pour material down the sink drain minimizing splashing.*
5. *Rinse out the material container if to dispose of, recycle, or reuse.*
6. *Clean sink to ensure sink basin is free of material.*
7. *Let tap water run for about two (2) minutes after pour to allow the material to flush through p-traps.*
8. *Shut off water taps to sink.*

CHEMICAL DETERMINATION FOR HAZARDOUS WASTE

If the chemical in question is not already on the "Chemicals Approved for Drain Disposal" list (see Appendix B), the NIH will need to determine if it is acceptable for disposal. **Generally, if the chemical waste is Ignitable, an Oxidizer, Corrosive, Reactive or Toxic, it is a hazardous waste that needs to be collected for disposal. Additionally, chemicals on EPA waste lists F, K, P, and U are identified as hazardous waste and subject to disposal regulations**. EPA periodically updates the CFR Title 40 – Protection of Environment, Volume 27, Part 261 – Identification and Listing of Hazardous Waste.

Chemical wastes that are already listed on the "Chemicals Approved for Drain Disposal" list (see Appendix B) are approved for disposal down the drain when not mixed with unapproved materials. If a chemical waste that is generated in your lab, does not appear on the list, you can request standing approval for drain disposal at DEP's Application for Disposal of Specific Chemical Reagents to the Sanitary Sewer. System wastes, disinfection wastes, or chemicals associated with disapproved mixtures will be approved on a case-by-case basis. If approved, the chemical will be added by DEP to the list of Chemicals Approved for Drain Disposal. If disapproved, collect as chemical waste and request pickup through waste disposal authority (see Appendix A).

WASTE CONTAINING ANTIBIOTICS

NIH is committed to avoiding the release of antibiotics that can reach the ecosystem. Autoclaving is the best practice and reliable means to inactivate antibiotics. Antibiotic waste must be treated differently depending on its stability. Request discharge to drain, with inactivation by other methods, requires an approval at DEP's Application for Disposal of Specific Chemical Reagents to the Sanitary Sewer.

Inactivate by heat (autoclave or boil) before pouring down the drain	Must be submitted for combustion (treated as **hazardous waste**)
Ampicillin	Blasticidin-S
Amphotericin B (Fungizone)	Choramphenicol
Carbenicillin	Ciprofloxacin
Erythromycin	Enrofloxacin
Geneticin (G418)	Kanamycin
Gentamicin	Nalidixic acid
Neomycin	Vancomycin
Penicillin	Zeocin
Puromycin	Zeomycin
Streptomycin	
Sulfadoxine	
Tetracycline	

Antibiotics not listed above should be collected as chemical waste. See waste services disposal guide for additional information.

LIQUID BIOHAZARDOUS WASTE DISPOSAL

Proper biohazardous waste treatment is important to ensure sterilization or deactivation prior to disposal. Biohazardous wastes consist of microbial cultures, viruses or recombinant DNA. Biosafety Risk Groups are designated 1 (agents with little risk to an individual or community) to 4 (agents with the highest risk to an individual or community). In this guide, only Risk Groups 1 and 2, with approval, will be considered for drain disposal. Risk Group 1 agents represent little to no risk to an individual or community. Risk Group 2 represents moderate risk to an individual but no risk to a community. Risk Groups 3 and 4 should be collected as Medical Pathological Waste (MPW). Risk Group 3 agents are serious or lethal human disease for which preventive or therapeutic interventions may be available. Risk Group 4 agents cause serious or lethal human disease without preventive or therapeutic interventions available. For more information, see DHHS's Biosafety Risk Groups. Biohazardous waste containing chemicals or radioactive waste should be collected for disposal through the appropriate waste management service

Below are the steps necessary for drain disposal of Risk Group 1 and 2 biohazardous wastes:

1. Wear appropriate PPE such as gloves, lab coat and eye protection when working with biohazardous waste
2. A bleach mixture (final concentration of 1:10 or 10%) for a contact time of a minimum of 20 minutes should be used to decontaminate biohazardous liquids. Once the liquid has been decontaminated, it can be poured down the drain. If using another disinfectant such as alcohol-based or Wescodyne® for decontamination, direct to the waste disposal guide for the appropriate disposal method.

NANOMATERIAL-CONTAINING WASTE

Chemical wastes containing nanoparticles shall not be disposed of as regular waste or poured down the drain (refer to the NIH Nanotechnology Safety and Health Program, 9.0 Waste, pages 7-8). Contact the waste management service for additional assistance with disposal recommendations for all nanomaterial related waste.

PHARMACEUTICAL WASTE

Hazardous pharmaceutical wastes governed by regulations under the Resource Conservation and Recovery Act (RCRA). Pharmaceuticals entering the environment via drain disposal have the potential to negatively impact aquatic ecosystems, including fish and animal populations, and can lead to water contamination and other public safety concerns. **Any pharmaceutical waste must be handled as chemical waste**. Pharmaceutical wastes are drugs, vaccines, and anti-neoplastic drugs; including contaminated pharmaceutical products and equipment. The acquisition, use and disposal of controlled substances at NIH is subject to strict Federal Drug Enforcement Administration (DEA) and State Department of Justice regulations. These regulations and directives set specific requirements and restrictions on registration, acquisition, usage, record keeping, transfer, storage and disposal.

Individuals who manufacture, distribute, dispense, import, export, conduct research or perform chemical analysis with any controlled substances including precursor chemicals are subject to a DEA registration.

APPENDIX B – EXPANDED LIST OF CHEMICAL SOLUTIONS APPROVED FOR DRAIN DISPOSAL

Note: (*) = allowable concentration limit (•) = antibiotic

A

A-Glucosidase, Type I
*Acetic Acid (≤10% with pH > 6)
Albumin, Bovine (without Sodium azide)
Albumin, Serum (Human) (without Sodium azide)
Alconox (≤1%) (10 g/L)
Alpha-D (+) Melibiose
•Amphotericin B (Fungizone) (Autoclave, pg. 5)
•Ampicillin (Autoclave, pg. 5)
*Animal Drinking Water (≤4% Deuterated Water)
Artificial Cerebrospinal Fluid (aCSF) (NaCl, $MgSO_4$, KCl, KH_2PO_4, Dextrose, $NaHCO_3$, $CaCl_2$, Kynureic Acid)

B

B-D (+) Glucose, and all Isomers – Beta D Glucose
Bacto Tryptic Soy Broth
Basal Medium Eagle
BD™ FACSFlow™ Sheath Fluid
Beta-Glucuronidase, Type VIII
Bicine [N, N-bis (2-hydroxyethyl) glycine]
Bile Salts
*Bleach (≤10% Clorox Bleach)
Blood Bank Saline
Bovine Serum Albumin (BSA)
Brain Slicing Perfusion Solution

C

Calcium Bicarbonate
Calcium Carbonate
Calcium Chloride
Calcium Citrate
Calcium Phosphate, Monobasic
Calcium Sulfate
•Carbenicillin (Autoclave, pg. 5)
Carboxypeptidase B
Carboxypeptidase Y

Carrageenan, Type II
Casein
Cellulase, all types
Chitin
Chondroitin
Chymotrypsinogen
Click's Medium
CM Cellulose Powder
Cocarboxylase
Coenzyme A, Sodium Salt

368. Abid Kazi

I am responding: On behalf of myself

Name: Abid Kazi

Name of Organization: Veteran Affairs - VAMC - Lebanon

Type of Organization: Government Agency

Role: Other

Role - Other: Health System Specialist

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Veteran Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Support for modernization and broader scope.
NIH's proposal to extend oversight beyond recombinant and synthetic nucleic acid research to include wild-type human pathogens, genetically modified organisms, toxins, and prions is appropriate and responsive to current scientific practice, and it aligns with stated goals to modernize biosafety and strengthen transparency and accountability.

Recommendation—clarify key terms to prevent inconsistent application.
Several terms central to scoping—particularly "biohazard," "biological agent," "genetic modification," and "genetically modified organism"—should be defined with greater precision in the policy text and/or companion guidance. Stakeholder comments indicate that definitional ambiguity could lead to inconsistent institutional interpretations, uneven review determinations, and confusion regarding coverage boundaries.
Address possible oversight gaps.

NIH should explicitly indicate whether research involving (a) non-pathogenic organisms engineered to express hazardous proteins, (b) prion-like, self-aggregating proteins not traditionally captured in RG frameworks, and (c) novel delivery platforms (e.g., gene drives) are fully encompassed under the draft scope, with cross-references to implementation resources or existing NIH considerations (e.g., gene drive materials) to avoid inadvertent gaps.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): General endorsement of tiering.
A tiered, risk-calibrated approach is appropriate and should reduce burden for well-characterized, lower-risk activities while directing federal attention to higher-risk or novel circumstances.

Recommendation—make thresholds and delegation criteria explicit.

The policy would benefit from clearly articulated criteria for when NIH review is required versus when IBCs may rely on published NIH precedents and local risk assessments. Stakeholder feedback encourages limiting NIH pre-approval to defined high-risk scenarios and allowing IBCs to manage routine low-risk work—improving timeliness without compromising safety.

Implementation consideration—resourcing for IBCs.
Because tiering transfers meaningful decision authority to IBCs, NIH should pair the model with implementation funding, training, and an escalation framework, ensuring that IBCs can consistently apply tiered oversight across institutions of varying capacity

3. Continued utility of Risk Groups: Balanced use of RGs and BSLs.
RGs provide a baseline hazard characterization anchored in pathogenicity and host range; BSLs translate risk into facility and practice requirements. For genetically modified agents, RGs alone may under- or over-estimate actual risk depending on phenotype; combining RG assignment with phenotype-informed adjustments and BMBL-aligned containment is preferable.

Recommendation—codify decision aids for modified agents.
NIH should include or reference practical decision aids that guide institutions in reconciling RG baselines with modified agent characteristics (e.g., altered tropism, attenuated virulence, novel delivery vectors) and in documenting the rationale for deviations from default RG-to-BSL mappings. A cross-walk or table of considerations, integrated with the draft's implementation resources, would enhance consistency.

Alignment with existing guidance.
Where NIH already provides focused biosafety considerations (e.g., gene drive modified organisms and other specialized areas), link these materials so committees can calibrate containment based on function and phenotype rather than nominal RG status alone.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Non-regulatory incentives.
To extend best practices beyond NIH-funded research, NIH could offer:

Access to training and templates (incident reporting, IBC minutes) and recognition programs for voluntary adopters (e.g., a registry or badge indicating alignment with NIH biosafety practices).
Model policies and implementation toolkits that smaller institutions can adapt, including staffing benchmarks, sample SOPs, and scalable digital reporting forms.

Collaborative networks and pilot programs.
NIH might seed regional biosafety collaboratives or pilot grants enabling non-funded institutions to adopt and evaluate the framework, building capacity through shared training and peer review. This approach responds to stakeholder concerns about resource gaps and could prevent uneven adoption.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Support for standardization.
Uniform templates can improve data quality and comparability across institutions, facilitating trend analysis and targeted prevention.

Recommendations to refine templates.

Proportional reporting thresholds: Clearly distinguish record-keeping vs. reportable incidents; provide examples to avoid over-reporting of near-misses that do not meaningfully inform safety improvements.
Privacy and IP protections: Include fields and instructions for redaction of confidential or proprietary information prior to public posting, balancing transparency with researcher privacy and institutional interests.
Machine-readable structure: Offer a data dictionary and machine-readable formats (e.g., CSV or JSON schemas) to streamline submission and enable analytics, especially if NIH proceeds with centralized incident aggregation and analysis.
Feedback loop: Provide guidance on corrective action documentation and standardized taxonomies for incident causes (e.g., human factors, equipment failure), improving cross-institution learning

6. Other feedback relevant to this resource: Implementation resources needed.

Phased timeline and readiness checklist: Publish phased milestones, staffing competencies, and minimum infrastructure requirements so institutions can plan budgets and hiring. Stakeholders have emphasized that new obligations—assurances, public postings, and expanded IBC roles—require proportionate support to avoid burden without safety gains.
IBC operations toolkit: Detailed guidance on IBC constitution, independence, escalation pathways, and integration with IRBs/IACUCs will promote consistency across the “three pillars” of oversight.
Costing guidance and funding mechanisms: Provide illustrative cost models (small, mid-size, large institutions), recommended FTEs, training budgets, and IT systems needs (for reporting, registries, public posting), alongside potential supplements or set-aside funds to offset implementation costs.
Special topics modules: Short, scenario-based resources (e.g., gene drive organisms, toxin work, prion-like proteins, lentiviral vectors) with containment rationales and example reviews to harmonize decisions nationwide.

Additional Note on Implementation Costs
Institutions—especially those with limited biosafety staffing—will incur non-trivial costs for policy adoption: new or expanded IBC operations, training, public-facing documentation systems, and incident analytics. To ensure the policy’s goals are met without disproportionate burden, NIH should (1) publish cost-impact assessments by institutional profile; (2) offer targeted funding or administrative supplements; and (3) stage implementation using pilot cohorts to validate resource assumptions and refine guidance. These steps reflect widely shared stakeholder concerns about pairing expanded responsibilities with practical authority, training, and support.

Description: Written response to the DRAFT policy.

Draft Formal Comments on NOT-OD-26-112: Draft NIH Biosafety Policy for Research Involving Biohazards

To Whom It May Concern:

Thank you for the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112). I appreciate NIH's efforts to modernize biosafety oversight and to develop a risk-based, transparent, and adaptive framework that reflects the evolving landscape of biomedical research. My comments below highlight areas of support as well as concerns regarding implementation feasibility, resource demands, and the potential impact on institutions of varying sizes and capacities.

1. Scope and Definitions

The expanded oversight of biohazards—including wild-type human pathogens, genetically modified organisms, toxins, and prions—represents an important modernization of biosafety governance. However, several key terms (e.g., 'biohazard,' 'genetic modification,' 'genetically modified organism') require clearer definitions to prevent inconsistent institutional interpretations and ensure accurate scoping of review responsibilities.

2. Risk-Based Oversight and Delegation Authorities

The introduction of risk-based review tiers and opportunities for delegated IBC review of lower-risk activities is a positive step toward streamlining oversight. Nonetheless, institutions would benefit from clearer thresholds for when NIH review is required versus when IBCs may rely on published precedents.

3. Administrative Burden and Implementation Costs

While the proposed framework aims to reduce administrative burden for low-risk research, the overall expansion of institutional obligations—including documentation, incident reporting, public posting requirements, assurances, and strengthened IBC functions—could impose significant new costs for institutions. This is of particular concern for smaller or resource-constrained organizations, which may lack dedicated biosafety infrastructure. Stakeholders have cautioned that without proportionate authority, resources, and training support, these expanded expectations may increase administrative workload without a corresponding improvement in risk mitigation.

I specifically urge NIH to:

• Provide clear cost-impact assessments for institutions of different sizes.

• Offer dedicated implementation funding or supplemental budget mechanisms for staffing, training, digital systems, and compliance activities.

• Consider a phased implementation schedule to allow institutions time to develop appropriate capabilities.

4. Reporting, Documentation, and Transparency Requirements

Standardized templates for incident reporting and IBC meeting minutes should improve consistency across institutions. However, stakeholders have noted the importance of balancing transparency with protection of confidential, sensitive, or proprietary information. Clear NIH guidance on redaction, privacy protections, and public-posting expectations would help institutions comply while safeguarding researcher privacy and intellectual property.

5. Expanded IBC Responsibilities and Required Institutional Support

The draft appropriately strengthens the role of the IBC as a core oversight body parallel to IRBs and IACUCs. Nevertheless, expanded responsibilities must be matched with commensurate authority, independence, and resource support. Biosafety professionals and IBCs need institutional backing—including staffing, training opportunities, and escalation pathways—to meet the expectations outlined in the policy.

6. Need for Additional Public Review and Implementation Resources

Given the scope of change proposed, further public review of implementation materials—including guidance documents, training resources, and reference tables—would help ensure successful adoption. Stakeholder groups have recommended an opportunity for comment on the next draft before finalization, noting current uncertainties related to institutional burden and operational feasibility.

Conclusion

NIH's modernization initiative is a vital step forward for biosafety oversight in the biomedical research enterprise. With further clarification of definitions, alignment of oversight thresholds, and the provision of adequate financial and operational support for implementation, the policy will be better positioned to achieve its goals of strengthening biosafety, enhancing accountability, and supporting safe research progress.

Thank you for considering these comments. I appreciate NIH's continued engagement with the research and biosafety community and look forward to future opportunities to contribute to the policy development process.

Description: Comments submitted by Angelo State University Institutional Biosafety Committee

Draft Biosafety Policy for Research Involving Biohazards
Replaces the current NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules

Comments Submitted by Angelo State University
Institutional Biosafety Committee (IBC)

The Angelo State University Institutional Biosafety Committee supports NIH's efforts to modernize and strengthen biosafety oversight and recognizes that many elements of the proposed policy are consistent with current institutional biosafety practices. We appreciate NIH's commitment to establishing a comprehensive, risk-based framework for research involving biohazards.

At the same time, the proposed expansion of scope, Biosafety Assurance requirements, incident-reporting obligations, and public disclosure provisions will create additional administrative and compliance responsibilities for institutions. We encourage NIH to provide clear implementation guidance, standardized templates, and adequate transition periods to support consistent adoption across institutions of varying size and capacity.

The Committee is particularly concerned about the proposed public posting of Institutional Biosafety Committee meeting minutes and incident reports. While transparency is an important objective, NIH should ensure appropriate safeguards protect confidential, proprietary, and security-sensitive information and give institutions flexibility in meeting public disclosure requirements.

Finally, we encourage NIH to consider the resource implications associated with these expanded requirements, particularly for smaller institutions with limited biosafety staffing and budgets. Maintaining a risk-based approach that preserves rigorous oversight of higher-risk research while allowing streamlined review of genuinely low-risk activities will support both effective biosafety governance and efficient use of institutional resources.

We appreciate the opportunity to provide comments and respectfully submit these recommendations for consideration.

AstraZeneca PLC
19 October 2026

National Institutes of Health
Office of Science Policy

Re: Request for Comment on Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear NIH Office of Science Policy:

AstraZeneca appreciates the opportunity to provide comments on the National Institutes of Health (NIH) Draft Biosafety Policy for Research Involving Biohazards. We support NIH's efforts to modernize biosafety oversight and establish a framework that reflects the evolving nature of biomedical research. The proposed policy represents a significant expansion of the current NIH Guidelines by extending oversight beyond recombinant and synthetic nucleic acid research to a broader range of biohazards. As a research-based biopharmaceutical company that may be subject to the policy through direct or indirect federal funding mechanisms, AstraZeneca has a strong interest in ensuring the final policy is clear, risk-based, operationally feasible, and adaptable to both academic and commercial research environments.

We respectfully offer the following observations and recommendations for NIH's consideration.

Transparency Requirements and Protection of Proprietary Information

AstraZeneca supports the policy's emphasis on transparency and public accountability in biosafety oversight. At the same time, we are concerned about the proposal requiring institutions to publicly post Institutional Biosafety Committee (IBC) meeting minutes and incident reports, as well as maintain publicly available IBC rosters.

While transparency is an important objective, commercial research organizations face unique challenges related to the protection of proprietary information, confidential business information, and intellectual property. In some circumstances, the absence of clear redaction standards may create uncertainty regarding the protection of proprietary information, confidential business information, and intellectual property, particularly when discussions involve novel technologies, development strategies, platform approaches, manufacturing activities, or other proprietary research.

AstraZeneca appreciates that the draft policy provides for “appropriate and allowable redactions” before IBC meeting minutes and incident reports are publicly posted and recognizes protection of proprietary interests as a relevant consideration in determining whether IBC meetings should be open to the public. However, AstraZeneca encourages NIH to provide explicit protections for

proprietary information, confidential business information and intellectual property, including clear guidance regarding the scope of "appropriate and allowable redactions" before IBC meeting minutes and incident reports are publicly posted. Such guidance should recognize the need to protect unpublished inventions, patent-sensitive technical information, trade secrets, confidential know-how, proprietary biological materials and constructs, unpublished research plans and results, and information subject to third-party confidentiality obligations.

NIH should also clarify that appropriately redacted records will satisfy the public-posting requirement, provided the public version adequately describes the biosafety assessment, safeguards imposed, and IBC disposition.

We also encourage NIH to evaluate whether public posting of individual IBC membership information is necessary in all circumstances and to consider employee privacy, security, and proprietary considerations for commercial organizations.

Authorized Organizational Representative (AOR) Responsibilities

The draft policy introduces a Biosafety Assurance mechanism submitted through an Authorized Organizational Representative (AOR), replacing certain existing registration and reporting requirements.

AstraZeneca supports efforts to streamline administration and reduce unnecessary burden; however, additional clarity regarding the role and responsibilities of the AOR would improve implementation. The final policy would benefit from a more detailed description of the authority, accountability, and expectations associated with the AOR function, including how this role interacts with the IBC Chair, Biological Safety Officer, institutional leadership, and broader compliance framework. Additional clarity regarding documentation requirements and oversight expectations during the four-year assurance period would also be helpful.

Applicability to Non-NIH-Funded Research

AstraZeneca requests additional clarification regarding the policy's applicability to non-NIH-funded research conducted at institutions that receive NIH funding.

Given the breadth of this provision, additional guidance would be helpful regarding how these requirements apply across large organizations, affiliates, subsidiaries, collaborative research arrangements, and independently funded research activities. Clarification in this area would help institutions understand the intended scope of compliance obligations and facilitate consistent implementation.

Institutional Biosafety Committee Governance

While the draft policy establishes requirements for IBC membership and responsibilities, AstraZeneca believes additional foundational guidance regarding IBC governance would be beneficial.

The final policy should further clarify the qualifications and responsibilities associated with positions such as the IBC Chair, Biological Safety Officer, community representatives, and institutional representatives. Additional guidance on training expectations and minimum competency standards would help promote consistency across institutions and ensure appropriate expertise is available for increasingly complex research activities.

Considerations for Commercial Research Organizations

AstraZeneca notes that the policy does not provide specific implementation considerations for commercial research organizations. Commercial research organizations may maintain biosafety governance structures that differ from traditional academic models.

Additional implementation guidance describing how such organizations can demonstrate compliance with the policy would be valuable and would help ensure consistent interpretation of requirements across different institutional settings.

Continued Role of Risk Groups

AstraZeneca believes Risk Groups remain an important and widely understood framework for hazard characterization, risk communication, and risk assessment.

We recommend maintaining Risk Group definitions and concepts within the final policy itself while continuing to support their use in conjunction with biosafety levels and project-specific risk assessments. Retaining these concepts in the policy would support consistency across institutions, facilitate implementation, and provide an important foundation for risk-based decision making.

Incident Reporting Thresholds and Definitions

AstraZeneca supports robust incident reporting systems and recognizes the value of collecting information that can improve biosafety practices across the research enterprise. However, greater clarity regarding incident-reporting thresholds would improve consistency and implementation.

Additional guidance would be helpful regarding the distinction between major and minor incidents, including consideration of factors such as the nature of the biological agent, containment level, volume involved, potential exposure risk, and potential environmental impact. Further clarification regarding what constitutes a "significant risk to human health," as well as illustrative examples of

reportable and non-reportable events, would promote more consistent decision making across institutions.

AstraZeneca also encourages NIH to describe how collected incident information will be analyzed and used to advance biosafety practices and whether aggregate lessons learned will be shared with the research community.

Clinical Research Considerations

The draft policy provides limited discussion regarding application of the framework to clinical research involving investigational products.

Additional guidance regarding how biosafety assessments should be conducted in clinical research settings would promote more consistent implementation across institutions. NIH should consider providing examples or supplemental guidance regarding the application of the policy to emerging therapeutic modalities and clarify when risk assessments may be sufficient to address biosafety considerations in clinical research settings.

Given the increasing use of complex modalities, including gene therapies, genetically modified cell therapies, and other advanced biologics, additional clarity would support consistent oversight while maintaining appropriate protections for research participants, personnel, and the public.

Delegated and Subcommittee Review Processes

The policy would benefit from additional detail regarding circumstances under which delegated, administrative, or subcommittee review may be used.

Further clarification regarding appropriate use of delegated review mechanisms would support efficient implementation while allowing committees to focus resources on higher-risk activities. Clear criteria distinguishing activities requiring full committee review from those suitable for delegated review would reduce administrative burden without compromising safety.

Guidance for Large-Scale Research Activities

AstraZeneca encourages NIH to ensure that sufficient guidance remains available regarding large-scale research activities and scale-up operations if information currently contained within the NIH Guidelines is relocated to supporting implementation materials.

Clear expectations for these activities will remain important for institutions conducting research beyond small laboratory scale and will help ensure consistent biosafety practices across a range of research and development environments.

Definitions and Terminology

Finally, AstraZeneca recommends that NIH ensure all acronyms and specialized terminology are clearly defined and used consistently throughout the policy and associated implementation materials.

A comprehensive glossary would improve usability, support consistent interpretation, and reduce ambiguity during implementation. Consistent terminology will be particularly important as the policy expands in scope and applicability across a broader range of research institutions and activities.

Conclusion

AstraZeneca appreciates NIH's commitment to modernizing biosafety oversight and welcomes continued engagement as the policy is finalized. We believe the recommendations outlined above would improve clarity, support consistent implementation across a diverse research ecosystem, and help achieve NIH's goals of enhancing biosafety, transparency, and accountability while preserving protection of confidential commercial information and enabling continued scientific innovation.

Thank you for the opportunity to provide comments on this important policy proposal.

Sincerely,

AstraZeneca PLC

372. Sahin Naqvi

I am responding: On behalf of myself

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Molecular biology, developmental biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am commenting specifically on NOT-OD-26-112, and specifically on the section "Genetic modification" within "General Definitions." This section states:

The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
- Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
- Have the potential for one or more cycles of replication in a cell; or
- Can be transcribed or translated;

Transient expression of nucleic acids that “can be transcribed or translated” is not a genetic modification by definition. For example, transient expression plasmids, even if provided as DNA, do not replicate within eukaryotic cells and cannot stably integrate into the genome. Similarly, mRNA delivered by transfection or nanoparticles cannot replicate and is only translated into protein products. Besides the incorrect biological assignment of such nucleic acids to genetic modifications, the proposal would also have unwanted practical implications: it would require the reporting of any transient expression system (which is incredibly widespread among the biomedical research community) as a Biohazard, adding a large amount of regulatory oversight and burden to scientists. This would achieve the opposite of what the proposal intends.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

373. Dr. Sandra Poulson

I am responding: On behalf of myself

Name: Dr. Sandra Poulson

Name of Organization:

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Pain Neurobiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of the new policy is too broad and does not take into consideration the low level of risk of use of Adeno-associated Viruses, one of the most ubiquitous and heavily used modern neuroscience tools. This tool has revolutionized how we study neurons and what neurons do and how they affect behavior, and yet this policy makes no mention or consideration for how this tool will be affected. If the scope does not take into account increasesed difficulty of using this tool, this policy is at risk of threatening the access and usage of this tool for all new neuroscience labs going forward. Careful consideration for not restricting the use of AAVs should be incoporated into the policy so that neuroscience research is not impeded.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Does not clearly define tiers of oversight; our Adeno-associated viruses are BSL-1 and pose little risk to users and to research models, but the draft leaves ambiguity in how these would be treated

3. Continued utility of Risk Groups: Explicit categorization of Adeno-associated viruses for use for neuroscience research needs to be addressed. Do not hinder neuroscience research with strict unnecessary oversight.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: There needs to be explicit incorporation for how Adeno-associated viruses, lenti viruses, modified replication deficient rabies viruses and associated helper viruses, and other modern neuroscience viral tools are handled. This policy seems to target gain-of-function viral research in light of the COVID-19 pandemic which is a laudable effort. But this policy does not take into account the viral tools that US neuroscientists use to study neural function and the effect on behavior. Explicit treatment of these viral tools needs to be outlines such that use in US laboratories is

not hindered to the point of restricting neuroscience research. More attention and care needs to be put into this policy to protect these modern tools.

374. American Association of Immunologists

I am responding: On behalf of an organization

Name: Emily Kansler, PhD

Name of Organization: American Association of Immunologists

Role: Other

Role - Other: Manager, Science Policy

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Immunology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The American Association of Immunologists (AAI) appreciates NIH's efforts to modernize and strengthen biosafety practices when conducting biomedical research. AAI supports NIH's goals of augmenting public safety, transparency, and accountability when it comes to biosafety, but believes that this policy, as written, would not make meaningful progress toward these goals. It would, however, significantly increase the burden on researchers and institutions and slow scientific progress. AAI elaborates on these concerns in each of the categories below.

The draft policy significantly expands the scope of research covered by NIH's current biosafety framework beyond research involving recombinant and synthetic nucleic acids to include all wild-type pathogens that cause disease in humans; all genetically modified cells, viruses, and organisms (other than plants) toxins, prions, and other self-aggregating proteins; and, cells and organisms (other than plants) that contain any of the above. This proposal appears to bring many experiments and types of research that have historically been considered to have no or low risk and to be exempt from Institutional Biosafety Committee (IBC) review into the new oversight framework (see Appendix C. Exemptions Under Section III-F-8 of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules). Much of this previously exempt and low-risk research will now require review and approval before initiation. While research listed under Section IV-3 of the current draft policy may be delegated to an individual or subgroup of IBC members, AAI is deeply concerned about the significant increase in administrative burden imposed on investigators, institutions, and IBCs. Further, AAI has significant hesitation about the feasibility of IBCs reviewing and approving such a vast expanse of research, especially when this additional review is unlikely to result in any meaningful improvement in biosafety. AAI urges NIH to carefully consider meaningful exemptions for research that is well characterized, routinely performed, and associated with little to no biosafety risk. Without such exemptions, as were previously allowed, AAI is concerned that IBCs will become overwhelmed with large volumes of low-risk protocols, potentially diverting attention from higher-risk activities that deserve more intensive scrutiny.

AAI is similarly alarmed about the substantial administrative burden imposed by the policy applying to all existing awards and ongoing research activities rather than only newly funded projects. Requiring institutions to retrospectively review large numbers of ongoing experiments will create substantial workload for investigators, IBCs, and institutions, potentially halting or delaying active research without a corresponding improvement in safety. AAI urges NIH to consider ways to reduce this burden and prioritize the review of higher-risk research.

The draft policy states that "as a term and condition for NIH funding, institutions shall ensure that any research conducted at or sponsored by the institution, irrespective of the source of funding, shall comply with this Policy." While AAI appreciates NIH's intent to standardize biosafety across the biomedical research enterprise, AAI is troubled that the policy would expand NIH oversight and authority to non-NIH funded projects. Any effort to harmonize how potentially risky research is conducted across federal agencies should be led by an entity that has broad oversight over federally funded scientific research, not by a single funding agency.

In addition, AAI believes that requiring "de novo registration submission and review" every three years, a new obligation not previously required under the old policy, is unnecessarily burdensome and disruptive for the investigator and IBC. Overall, many aspects of this policy place substantial workload and capacity requirements upon the IBC and individual investigators, without additional support. AAI is particularly concerned that smaller institutions with less resources may be excessively burdened by this policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): AAI supports the principle that biosafety oversight should be calibrated to risk, and that higher-risk research should receive greater examination than lower-risk research. The delegated review pathway under Section IV-3 is well-intentioned; however, AAI believes the draft policy should provide clearer oversight mechanisms for institutions to conduct streamlined or minimal reviews (if not exemptions) of research previously known to be low risk (e.g., research conducted with transgenic organisms at BSL-1/ABSL-1). Delegating review and approval to one or a subgroup of IBC members only increases the burden on one or more individuals who may or may not have the expertise to accurately determine biosafety risk. Research exempt under the previous policy should, at minimum, undergo an expedited or streamlined review process to reduce administrative burden that otherwise has no clear safety benefit. This approach would better align oversight requirements with actual risk and preserve IBC capacity for activities with true biosafety concerns.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: AAI appreciates that NIH places transparency at the forefront of its biosafety policy and supports efforts to standardize incident reporting in ways that facilitate the identification of systemic biosafety issues and promote continuous improvement. At the same time, AAI encourages NIH to carefully consider the unintended consequences of requiring public posting of all incident reports, in part because incidence reports must contain identifiable information such as principal investigator names and position titles of individuals

involved in an incident. Providing even this information, alongside publicly available lab websites that list personnel, enables easy identification of those involved. This raises privacy and security concerns for investigators, research staff, and institutions. In some research areas, including clinical studies and research involving animals, researchers and institutions may be subject to heightened public attention or scrutiny. To balance transparency with safety and privacy concerns, NIH should consider limiting the disclosure of and protecting personally identifiable information.

In addition, mandatory public posting of all incidents, including low-risk incidents, could have the unintended consequence of discouraging reporting if public disclosure carries reputational or personal concerns. If NIH's objective is to strengthen biosecurity practices and identify meaningful areas of improvement or risk across the biomedical research enterprise, AAI encourages NIH to consider mechanisms that better protect individual identities, including anonymous reporting.

6. Other feedback relevant to this resource: AAI appreciates NIH's commitment to providing additional guidance through supplemental materials and implementation resources. Given the significant expansion in scope of the draft policy, AAI urges NIH to provide specific guidance for the newly covered areas (wild-type pathogens, toxins, etc.) since institutions and IBCs may need to build oversight capacity from scratch. Similarly, guidance should include concrete risk-assessment examples across a range of research types. NIH may also consider developing a tool for investigators and IBCs to quickly determine which oversight tier is appropriate for assessment of a proposal. These resources should be made available well before the implementation date.

Finally, AAI worries that the proposed implementation deadline of six months from final policy publication is inadequate, especially for smaller institutions and/or those without an existing IBC or biosafety oversight infrastructure. In addition, given the expanded scope, current IBCs may lack members with relevant expertise and need sufficient time to establish an appropriate roster.

Submission by the American Association of Immunologists (AAI) in response to the National Institutes of Health (NIH) Request for Information (RFI): Draft NIH Biosafety Policy for Research Involving Biohazards

October 19, 2026

The American Association of Immunologists (AAI) appreciates NIH's efforts to modernize and strengthen biosafety practices when conducting biomedical research. AAI supports NIH's goals of augmenting public safety, transparency, and accountability when it comes to biosafety, but believes that this policy, as written, would not make meaningful progress toward these goals. It would, however, significantly increase the burden on researchers and institutions and slow scientific progress. AAI elaborates on these concerns in each of the categories below.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

The draft policy significantly expands the scope of research covered by NIH's current biosafety framework beyond research involving recombinant and synthetic nucleic acids to include all wild-type pathogens that cause disease in humans; all genetically modified cells, viruses, and organisms (other than plants) toxins, prions, and other self-aggregating proteins; and, cells and organisms (other than plants) that contain any of the above. This proposal appears to bring many experiments and types of research that have historically been considered to have no or low risk and to be exempt from Institutional Biosafety Committee (IBC) review into the new oversight framework (see Appendix C. Exemptions Under Section III-F-8 of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules). Much of this previously exempt and low-risk research will now require review and approval before initiation. While research listed under Section IV-3 of the current draft policy may be delegated to an individual or subgroup of IBC members, AAI is deeply concerned about the significant increase in administrative burden imposed on investigators, institutions, and IBCs. Further, AAI has significant hesitation about the feasibility of IBCs reviewing and approving such a vast expanse of research, especially when this additional review is unlikely to result in any meaningful improvement in biosafety. AAI urges NIH to carefully consider meaningful exemptions for research that is well characterized, routinely performed, and associated with little to no biosafety risk. Without such exemptions, as were previously allowed, AAI is concerned that IBCs will become overwhelmed with large volumes of low-risk protocols, potentially diverting attention from higher-risk activities that deserve more intensive scrutiny.

AAI is similarly alarmed about the substantial administrative burden imposed by the policy applying to all existing awards and ongoing research activities rather than only newly funded projects. Requiring

institutions to retrospectively review large numbers of ongoing experiments will create substantial workload for investigators, IBCs, and institutions, potentially halting or delaying active research without a corresponding improvement in safety. AAI urges NIH to consider ways to reduce this burden and prioritize the review of higher-risk research.

The draft policy states that "as a term and condition for NIH funding, institutions shall ensure that any research conducted at or sponsored by the institution, irrespective of the source of funding, shall comply with this Policy." While AAI appreciates NIH's intent to standardize biosafety across the biomedical research enterprise, AAI is troubled that the policy would expand NIH oversight and authority to non-NIH funded projects. Any effort to harmonize how potentially risky research is conducted across federal agencies should be led by an entity that has broad oversight over federally funded scientific research, not by a single funding agency.

In addition, AAI believes that requiring "*de novo* registration submission and review" every three years, a new obligation not previously required under the old policy, is unnecessarily burdensome and disruptive for the investigator and IBC. Overall, many aspects of this policy place substantial workload and capacity requirements upon the IBC and individual investigators, without additional support. AAI is particularly concerned that smaller institutions with less resources may be excessively burdened by this policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).

AAI supports the principle that biosafety oversight should be calibrated to risk, and that higher-risk research should receive greater examination than lower-risk research. The delegated review pathway under Section IV-3 is well-intentioned; however, AAI believes the draft policy should provide clearer oversight mechanisms for institutions to conduct streamlined or minimal reviews (if not exemptions) of research previously known to be low risk (e.g., research conducted with transgenic organisms at BSL-1/ABSL-1). Delegating review and approval to one or a subgroup of IBC members only increases the burden on one or more individuals who may or may not have the expertise to accurately determine biosafety risk. Research exempt under the previous policy should, at minimum, undergo an expedited or streamlined review process to reduce administrative burden that otherwise has no clear safety benefit. This approach would better align oversight requirements with actual risk and preserve IBC capacity for activities with true biosafety concerns.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.

AAI appreciates that NIH places transparency at the forefront of its biosafety policy and supports efforts to standardize incident reporting in ways that facilitate the identification of systemic biosafety issues and promote continuous improvement. At the same time, AAI encourages NIH to carefully consider the

unintended consequences of requiring public posting of all incident reports, in part because incidence reports must contain identifiable information such as principal investigator names and position titles of individuals involved in an incident. Providing even this information, alongside publicly available lab websites that list personnel, enables easy identification of those involved. This raises privacy and security concerns for investigators, research staff, and institutions. In some research areas, including clinical studies and research involving animals, researchers and institutions may be subject to heightened public attention or scrutiny. To balance transparency with safety and privacy concerns, NIH should consider limiting the disclosure of and protecting personally identifiable information.

In addition, mandatory public posting of all incidents, including low-risk incidents, could have the unintended consequence of discouraging reporting if public disclosure carries reputational or personal concerns. If NIH's objective is to strengthen biosecurity practices and identify meaningful areas of improvement or risk across the biomedical research enterprise, AAI encourages NIH to consider mechanisms that better protect individual identities, including anonymous reporting.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

AAI appreciates NIH's commitment to providing additional guidance through supplemental materials and implementation resources. Given the significant expansion in scope of the draft policy, AAI urges NIH to provide specific guidance for the newly covered areas (wild-type pathogens, toxins, etc.) since institutions and IBCs may need to build oversight capacity from scratch. Similarly, guidance should include concrete risk-assessment examples across a range of research types. NIH may also consider developing a tool for investigators and IBCs to quickly determine which oversight tier is appropriate for assessment of a proposal. These resources should be made available well before the implementation date.

Finally, AAI worries that the proposed implementation deadline of six months from final policy publication is inadequate, especially for smaller institutions and/or those without an existing IBC or biosafety oversight infrastructure. In addition, given the expanded scope, current IBCs may lack members with relevant expertise and need sufficient time to establish an appropriate roster.

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Neuroscience

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: My lab uses adeno-associated viral (AAV) vectors to investigate how genes and proteins in specific brain cell types contribute to pain and addiction. These are engineered tools that are used routinely by labs across the country. Specifically, they cannot replicate, do not cause disease, and are classified at the lowest biosafety level (BSL-1) by our institution. Every AAV that we use has already been reviewed and approved by our Institutional Biosafety Committee (IBC). The draft policy would disrupt this rigorous approval process without providing any guidance on next steps or implementation of the policy.

Researchers, like myself, are left with an unclear picture of what will happen to already approved research. Can we keep working under our current approvals or do we need to pause active, funded projects? Do we have to resubmit everything from scratch once the policy is in place? Can we amend existing protocols? Without clear answers, institutions will take the safest legal route: stop everything and resubmit. This could set our research back by months or more for tools that have already undergone risk assessment and have been in use for years. The impact on innovation and expedient dissemination of results would be immediate.

The draft also lumps all viral vector research into a single broad category without the practical guidance that the current NIH Guidelines provide. The existing guidelines include specific, usable direction for common research tools like AAVs — what containment is required, how to assess risk, what paperwork is needed. The new policy removes all of that without replacing it. Investigators and biosafety committees will be left guessing, and different institutions will interpret the rules differently, creating a patchwork of inconsistent oversight across the country. Overall, the policy creates a broad new biosafety framework without providing enough specific, operational guidance for one of the most common experimental platforms in basic neuroscience.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The three-year renewal requirement is the most troublesome piece of this draft for our group's research. We have hundreds of approved AAV constructs. Every three years, we would need to resubmit them all; vectors that have not changed, that have been used safely year after year, that our IBC has already reviewed and

approved. There is no safety justification for this. NIH should allow institutions to use a "master protocol" approach, where a single protocol covers an entire class of well-characterized vectors, with individual new constructs added through a simple review process. Resubmitting hundreds of unchanged protocols every three years is not a safety measure.

What the draft also does not acknowledge is the real cost of all this compliance work. Tracking renewal deadlines for hundreds of constructs, preparing detailed incident reports within 24 hours, managing the public posting of meeting minutes, meeting new committee composition requirements; none of this happens for free. Most research labs do not have dedicated administrative staff for biosafety compliance. The practical result is that someone in the lab, a postdoc, a lab manager, the PI, will have to do it, taking time away from research. Or the lab will need to hire additional staff, which means spending grant money on administration instead of science. NIH has not estimated what this policy will cost the research community, and it should before moving forward.

The concept of tiered oversight, or matching the level of review to the actual level of risk, is the right approach in principle. However, the draft doe not define the tiers clearly enough to use them. Our AAVs are BSL-1 materials: the lowest risk category that exists. They cannot replicate, they do not cause disease in healthy people, and they have been used safely in research laboratories for decades. Yet under this draft, it is not clear that they would qualify for a lighter-touch review track. Without explicit criteria, our institution will default to full IBC review for everything, adding months of overhead for materials that pose no meaningful hazard. The impact will be felt most by those who can least afford it. Junior faculty who are just starting their labs are building their research programs from scratch, generating new AAV constructs, and submitting initial protocols. Graduate students and postdoctoral researchers are also directly harmed. NIH has invested heavily in fellowship and training programs specifically designed to help trainees complete their work on time. Administrative delays caused by this policy work directly against those investments.

3. Continued utility of Risk Groups: Our AAVs start from a naturally occurring virus, but that virus has been extensively modified. Specifically, key genes that allow it to replicate have been removed entirely. What remains cannot reproduce, cannot spread, and cannot cause disease. Our institution classifies these vectors as BSL-1 specifically because of those modifications. But if risk classification starts from the parental virus's RG category, none of that transformation is captured. We would be assessed against the natural virus, not the tool we actually use.

Biosafety Levels (BSLs) are a better fit for this kind of work because they describe what safety practices are actually required in the lab. Our AAVs are classified BSL-1, meaning they require standard lab practices and no special containment. That classification reflects the actual risk of working with these materials. I strongly recommend that BSL serve as the primary framework for classifying genetically modified research tools, with RG used only as a starting point when the research involves or is closely related to the natural, unmodified version of an agent. If RG is kept as the primary system, the policy must spell out exactly how classifications are adjusted for genetic modification. As it stands, different institutions are making those adjustments differently, leading to inconsistent and sometimes arbitrary differences in what is allowed and under what conditions.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The draft does not give non-NIH institutions a realistic path to implement the biosafety practices expected of NIH-funded institutions. The main obstacle for most of these institutions is not willingness, but capacity. Many may not have a full-time biosafety officer, an established safety committee, or staff with experience reviewing viral vector research. Asking them to voluntarily adopt a complex new framework without providing model templates, training resources, or step-by-step guidance is not a strategy that will work. Voluntary compliance provisions need to be paired with real tools that make compliance achievable for smaller or less-resourced institutions.

The draft also misses an important opportunity to reduce unnecessary duplication. Some non-NIH institutions are already operating under rigorous federal safety oversight via the CDC, USDA, FDA, or DOD. They are not operating without safeguards; they are operating under different but comparably strict ones. Rather than requiring these institutions to build a parallel compliance structure just to meet NIH's framework, the policy should formally recognize equivalent oversight programs.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting template requires a report within 24 hours for any "serious" incident, but the template never defines what "serious" means for research using BSL-1 viral vectors. A needlestick during an AAV injection is not the same as an exposure to a dangerous pathogen, but the draft treats them as if the same reporting process applies. Without a clear, practical definition that accounts for what the actual material is and what real risk it poses, labs and biosafety offices will not know how to apply this requirement consistently. Some will report everything out of caution; others will under-report. Neither is the right outcome. The template needs to include plain-language guidance that helps labs determine whether a given event actually requires a 24-hour report.

The public posting requirement for IBC meeting minutes raises a serious problem that the template does not address at all. IBC minutes describe ongoing research often in detail and often before that research has been published or patented. Posting five years of unredacted minutes publicly would expose unpublished findings, novel research tools, and investigator-specific information. This is not a hypothetical concern; it is a predictable consequence of the requirement as written. The template must specify what can and cannot be redacted before posting, and institutions need clear legal authority to make those redactions. Without that, the requirement will either discourage candid discussion in IBC meetings or result in researchers' unpublished work becoming public. The template also needs to allow batch review entries for labs with many similar constructs. Requiring a separate detailed entry for each of hundreds of nearly identical AAV vectors would make meeting minutes unmanageably long.

6. Other feedback relevant to this resource: This draft cannot be put into practice as written. Too many of the questions that labs and biosafety committees need answered are left for "future guidance". However, the six-month implementation clock starts when the policy is finalized, not when the guidance is ready. That means institutions will be expected to comply with a policy they cannot yet fully interpret. The result will be inconsistency, confusion, and for many labs research pause while they wait for clarity.

An effective date should not be set until the supporting guidance is finalized and publicly available. Six months is not enough time to restructure compliance systems when the practical meaning of the policy is still being worked out. Clear written direction for labs with existing IBC approvals needs to be provided.

Are current approvals still valid? Do we have to resubmit? Can we amend existing protocols? Without explicit answers to these basic questions, institutions will require full resubmission of everything to be safe. Transparency and honesty about what this policy will cost is necessary. Keeping up with renewal deadlines, writing 24-hour incident reports, managing public minute posting, and meeting new committee requirements all take real time and real money. Most labs do not have the staff to absorb this. Investigators will either redirect their own time from research to paperwork, or spend grant funding on additional administrative personnel. NIH has not estimated this cost or weighed it against the safety benefits. It should.

The impact on junior faculty and trainees should be acknowledged and addressed. A new faculty member building their lab from scratch, generating their first AAV constructs, and establishing their IBC protocols is in a fundamentally different position than an established lab. They have less staff, less institutional support, and less margin for administrative delays. NIH also funds thousands of graduate students and postdocs through fellowships and training grants built on the assumption that trainees can complete their work on schedule. Paperwork-driven delays undermine that assumption directly. NIH should be required to assess the impact of this policy on trainee timelines and early-career productivity before it is finalized.

376. People for the Ethical Treatment of Animals

I am responding: On behalf of an organization

Name:

Name of Organization: People for the Ethical Treatment of Animals

Type of Organization: Non-Profit Research Organization

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We support NIH's proposed expansion of biosafety oversight beyond recombinant and synthetic nucleic acid research to encompass a broader range of biological hazards. The expanded scope appropriately recognizes that biosafety risks are not limited to genetically modified agents and can arise from wild-type pathogens and other biological materials. The draft policy specifically notes that oversight would include wild-type agents and other biohazards, which is an important modernization of the current framework.

However, the draft creates a significant gap in oversight for zoonotic pathogens carried by animals used in experiments, particularly imported nonhuman primates. Imported nonhuman primates may harbor zoonotic pathogens unrelated to the approved research project, including pathogens that are not readily identified through routine screening. For example, the CDC has reported multiple cases of melioidosis caused by Burkholderia pseudomallei in imported macaques from Cambodia.1 B. pseudomallei is a Tier 1 Select Agent and can cause severe disease in humans. Tuberculosis has also been documented in imported macaques, including Mycobacterium orygis, which was identified in macaques from Southeast Asia and had not previously been documented in nonhuman primates imported into the United States.2 Cases of tuberculosis have also been identified after mandatory import quarantine, highlighting the limitations of routine screening and the potential for infections to go undetected.3 Antimicrobial-resistant bacteria are another concern, as they can cause serious infections that are difficult to treat. In 2023, vancomycin-resistant Staphylococcus aureus, a rare and highly drug-resistant bacterium, was identified in macaques imported from Mauritius and housed at the Oregon National Primate Research Center.4 Herpes B virus is also widespread among adult macaques, and infected animals can shed the virus without showing symptoms, posing a potentially fatal risk to humans. Routine screening for the virus is not required during import quarantine. CDC has also noted that imported nonhuman primates may develop disease months or years after importation, and that human exposure can occur through contact with infectious animal materials and bodily fluids.

The policy excludes many exposures to adventitious agents from federal reporting unless they result in a laboratory-acquired infection. While these agents may not be the focus of the experimental protocol,

they present substantial occupational and public health risks.

This oversight is at odds with the draft policy's broader recognition of zoonotic hazards. NIH defines a zoonotic agent as one reasonably suspected of transmission from animals to humans with the potential to cause human disease and establishes federal involvement in determining appropriate containment for certain emerging, novel, or zoonotic biological agents.

Whether a pathogen was deliberately introduced as part of an experiment or was carried by an animal does not determine the potential consequences of an exposure. The final policy should ensure that exposures to zoonotic pathogens associated with animals used in experiments are treated as biosafety events even when the pathogen is not part of the experimental protocol and no infection is ultimately confirmed. These exposures warrant federal attention and analysis.

Front Immunol. 2023;14:1244637. doi:10.3389/fimmu.2023.1244637

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed delineation between local and federal oversight may understate risks associated with zoonotic exposures involving nonhuman primates.

The draft policy identifies events such as animal bites, scratches, escapes, improper disposition, and other incidents involving animals housed in BSL-1/ABSL-1 or BSL-2/ABSL-2 facilities to local IBC review, without required reporting to NIH. It also specifically exempts treatment following potential exposure to adventitious agents such as nonhuman primate Herpes B or B. pseudomallei from NIH reporting unless a laboratory-acquired infection occurs. These provisions risk hiding information that could reveal recurring hazards associated with the use of particular animals or animal sources, even those used by facilities in different local jurisdictions, which could create risks beyond a single institution.

Federal oversight should be required for:

*Any bites, scratches, and mucosal exposures involving imported nonhuman primates.
*Incidents requiring post-exposure prophylaxis or precautionary medical treatment following exposure to imported nonhuman primates.
*Detection of significant zoonotic pathogens in imported nonhuman primates used in NIH-funded research.

These incidents should not be treated solely as local occupational health matters because they provide important information about broader biosafety risks across the research enterprise. Federal reporting would enable NIH to determine whether patterns exist across institutions, species, animal sources, or types of experiments that cannot be identified through isolated institutional review.

NIH should also resist treating administrative burden as a reason to exclude genuine hazards from meaningful oversight. The draft policy is explicitly intended to calibrate oversight to risk. Where an activity presents a significant occupational or public health hazard, additional review, documentation, and reporting are appropriate consequences of that risk.

3. Continued utility of Risk Groups: No comment

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): For institutions and other entities not subject to the policy, NIH should encourage adoption of the same core principles for research involving biohazards, including meaningful incident reporting, public transparency, and oversight of zoonotic hazards associated with animals used in experiments. An institution's biosafety accountability should not be stronger or weaker based on its funding sources.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: There must be meaningful public transparency regarding biosafety incidents. We urge NIH to retain its requirements for public posting of IBC meeting minutes and incident reports.

The public has a legitimate interest in knowing where federally supported research involving biological hazards is conducted, the nature of biosafety incidents associated with that research, and what actions institutions take in response. Aggregate reporting alone would make it substantially more difficult for the public to identify recurring problems associated with particular institutions, projects, or research practices. NIH should therefore preserve disclosure of information necessary for meaningful accountability while allowing appropriate redaction of personally identifiable and medical information concerning individual workers.

The Draft Incident Reporting Template should be revised to capture exposure incidents involving zoonotic pathogens carried by animals in laboratories, even when no laboratory-acquired infection is ultimately confirmed.

Specifically, the reporting template should include fields for:

*Animal species involved in the incident
*Whether the animal was imported and country of origin
*Whether post-exposure prophylaxis or precautionary treatment was administered
*Whether the exposure involved a known or suspected zoonotic pathogen
*Whether pathogen testing was conducted following the incident and the results of that testing

For the Draft Meeting Minutes Template, NIH should encourage IBCs to document discussions involving zoonotic disease risks associated with animals used in experimentation, particularly imported nonhuman

primates, and how the committee evaluated relevant zoonotic hazards and what corrective or preventive measures were considered. This information would improve NIH's ability to identify recurring risks, evaluate trends across institutions, and determine whether additional safeguards are warranted, as well as improve transparency and institutional decision making.

6. Other feedback relevant to this resource: NIH should issue additional guidance regarding zoonotic hazards associated with animals used in experiments, particularly imported nonhuman primates, when those hazards exist independently of the experiment's intended biological agent.

NIH should also ensure that its proposed National Biosafety Data and Safety Analysis Center can identify patterns involving animals used in experimentation. The draft establishes the Center to aggregate, de-identify, and analyze incident data, near misses, and anomalies. For incidents involving animals, standardized data should therefore identify the species involved and the animals' origin, as well as whether a known or suspected zoonotic agent and subsequent medical treatment were involved. This information would allow NIH to determine whether particular species, sources, or research practices are repeatedly associated with biosafety incidents.

Overall, the draft policy is a significant step toward modernizing biosafety oversight by expanding its scope beyond recombinant and synthetic nucleic acid research. But a modernized policy should evaluate a biological hazard based on the risk it actually presents, not on whether that hazard was deliberately introduced as part of an experiment. The final policy should close the adventitious-agent reporting gap, require federal reporting of consequential zoonotic exposures involving these animals, collect animal-specific information necessary to identify patterns across institutions, and preserve meaningful public access to incident and oversight information. Doing so would better align the policy with NIH's goals of accountability, transparency, and protection of public health.

377. Association of Public Health Laboratories

I am responding: On behalf of an organization

Name:

Name of Organization: Association of Public Health Laboratories

Type of Organization: Professional Organization/Association

Role: Other

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Association of Public Health Labs

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The current definition of biomedical research leaves some uncertainty about which activities are covered and where PHLs fall within the scope of the new policy. PHLs conduct applied research to improve testing and detection of agents of public health concern, a critical activity for effectively responding to emerging biological and chemical threats. During responses to threats such as Zika, Ebola, and global pandemics, PHLs may need to rapidly evaluate, adapt, or improve testing methods as new information and technologies become available. These activities directly support public health response efforts and should not unintentionally trigger additional research oversight requirements that could delay implementation of needed testing.
APHL recommends that NIH clarify this definition to distinguish applied research conducted as part of PHL operations from research intended to be covered by the policy, and to make it clear that PHL test development and improvements are outside the policy's scope.
PHLs may be affiliated with academic institutions, collaborate on NIH-funded research, or provide specialized testing services for research projects. In specific instances where these research collaborations fall within the scope of NIH Policy, APHL understands that PHLs' participation in the research project would be subject to the biosafety oversight requirements and assurances of NIH-regulated collaborators, where applicable. However, APHL's understanding is that these relationships would not, on their own, bring unrelated PHL diagnostic testing and applied research activities within the scope of the policy.
APHL asks NIH to confirm these interpretations and clarify any circumstances under which the policy would apply to PHLs. If certain PHL applied research activities are intended to be covered, additional information is needed on which activities would be affected and what requirements would apply, so that APHL can further evaluate how those requirements could affect PHL operations.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): APHL supports opportunities for PHLs and other laboratory sectors to voluntarily contribute to national biosafety initiatives, including the proposed National Biosafety Data and Safety Analysis Center.

APHL's Biosafety and Biosecurity Committee (BBC) has identified the need for a national approach to the collection and analysis of biosafety data. Currently, limited information is available to assess laboratory incidents and identify common risks and trends across laboratory settings. A national resource for this information would provide all laboratories with a better understanding of where safety improvements are needed and help inform risk assessments, training, and other biorisk management practices. Encouraging participation across both private and public laboratory sectors will be important to the success of this effort. Laboratories must have confidence that information shared through the Center will be handled appropriately, sensitive information will be protected, and reporting will not be used to penalize institutions. Establishing this trust will help encourage participation and the sharing of lessons learned.

APHL encourages NIH to provide opportunities for voluntary, confidential participation by PHLs and other laboratories, regardless of whether they are subject to the policy. This would allow the broader laboratory community to contribute to and benefit from national biosafety data without creating additional oversight requirements for laboratories outside the policy's intended scope.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: APHL encourages NIH to retain and emphasize the provision in Appendix G-II-C-5 that requires consultation with the public health authority for facilities conducting research involving Risk Group 3 agents with potential for societal consequences (e.g., RG3 influenza viruses, SARS-CoV/SARS-CoV-2 chimeric viruses, etc.). Public health laboratories and other public health authorities can provide important expertise on surveillance, testing capacity, preparedness, and response considerations associated with these agents. This consultation can also help ensure that potential public health impacts and the availability of appropriate tests are considered in institutional biosafety planning.

NIH should also consider providing guidance on opportunities for qualified PHL representatives to participate in or serve as subject-matter experts on Institutional Biosafety Committees (IBCs), particularly when research involves agents of significant public health concern. Greater engagement between research institutions and public health authorities could strengthen communication, support preparedness, and help ensure coordination when an incident may require a broader public health response.

6. Other feedback relevant to this resource: N/A

378. Phillip Sharp

I am responding: On behalf of myself

Name: Phillip Sharp

Name of Organization: MIT

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cell and Cancer Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The current proposed in the definition of biohazards is not based in current science. In the 50 years since the initial guidelines from NIH, there has not been a laboratory experiment that has definitively produced a sickness or a biohazard. The current guidelines has been repeatedly update and are more than adequate to protect the community. The proposed guidelines create redundant reporting and include reporting that could be unrelated to recombinant DNA. This will slow progress in a critical field of research with no obvious advantage.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Recombinant DNA and biohazards have been regulated for over 50 years by NIH. Periodic revisions of the guidelines are appropriate. These proposed guidelines are not appropriate and will increase cost and delay discovery.

3. Continued utility of Risk Groups: There are other regulatory agencies of NIH that assign Risk Groups and these risk groups are acknowledged in the BSL based guidelines. The training of personnel for experimental protocol and conditions for experimentation are also part of BSL. The BSL system does not need to be replaced by the BMBL system which expands reporting that overlap other regulatory reporting and supervision.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I expect NIH currently has a public facing Hot Line where anonymous individuals can report breeches of guidelines or the research related to the generation of biohazards. These need to be supported with an awareness campaign. If it does not currently exist there needs to be a government wide committee that integrates intelligence about dangerous activities. This includes monitoring of social media. Finally private companies should be aware that use of their services that create biohazards are a liability that should not be ignored.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: As far as I am aware, the process that generated these signifiant changes did not engage a broad sector of the actors who will be regulated by them. I do not think these proposed guidelines have gained support by the boarder community.

Uploaded File: NIH-Biosafety-Policy-Comments.docx

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

Topic to Address*: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:
    a. the nature and stability of the genomic modification;
    b. whether the modification is heritable and the potential for transmission through breeding;
    c. effects on animal health, phenotype, host range, susceptibility, or disease;
    d. potential entry into breeding or food-production systems;
    e. potential environmental release or interaction with non-research animal populations;
    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and
    g. applicable federal, state, or other regulatory oversight.
2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

    Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

The biosafety and biosecurity community believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In an earlier response, the biosafety and biosecurity community requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, the biosafety and biosecurity community welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. The biosafety and biosecurity community does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. The biosafety and biosecurity community recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, The biosafety and biosecurity community recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with our earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. the biosafety and biosecurity community recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, the biosafety and biosecurity community kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. The biosafety and biosecurity community encourages NIH to work collaboratively with us to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While the biosafety and biosecurity community supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: The biosafety and biosecurity community recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. The biosafety and biosecurity community supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Institutional Response from Drexel University to NIH

Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Drexel University appreciates the opportunity to provide feedback on the Draft NIH Biosafety Policy for Research Involving Biohazards. We support NIH's goal of strengthening biosafety oversight while encouraging a framework that is risk-based, practical to implement, and appropriately focused on activities that present meaningful biosafety risk. We do, however, recognize the potential for additional red tape, administrative burdens, and financial costs for both the federal government and research institutions, particularly when these requirements may not be necessary or appropriate for all federally funded research.

After soliciting input from Drexel investigators, biosafety stakeholders, and institutional compliance personnel, we provide the following recommendations and comments on the draft policy:

Key Recommendations

1. Maintain a Risk-Based Oversight Framework

Drexel strongly encourages NIH to preserve and enhance a risk-based approach to biosafety oversight. Requirements should be proportional to the level of biological risk and potential impact associated with research activity.

Specifically, NIH should:

- Differentiate oversight, reporting, and review requirements based on biosafety level, agent characteristics, and incident severity.
- Focus expanded requirements on research activities that present substantive biosafety concerns rather than broadly applying identical requirements to low- and high-risk work.
- Ensure that reporting thresholds are calibrated to meaningful risk and do not create unnecessary reporting obligations for minor events.
- Provide additional guidance, examples, templates, and decision tools to support consistent risk assessment and mitigation practices across institutions.

2. Preserve Existing Exemptions for Low-Risk Research

Drexel is concerned that the draft policy may unintentionally expand oversight requirements for activities that have historically been recognized as low risk.

We recommend that NIH:

- Clarify treatment of historically exempt activities under the NIH Guidelines.
- Retain current exemptions for routine ABSL-1 and comparable low-risk transgenic animal activities.
- Preserve exemptions for routine colony maintenance, breeding, purchase, and transfer of qualifying transgenic or knockout rodents.
- Clearly distinguish routine animal husbandry and colony management activities from higher-risk genetic manipulation or pathogen research activities.
- Avoid imposing registration or review requirements for activities that have not demonstrated significant biosafety concerns.

Expanding review requirements for routine low-risk transgenic animal work could significantly increase administrative volume without providing a commensurate biosafety benefit.

3. Minimize Administrative Burden and Resource Impact

The proposed policy introduces several new oversight, documentation, reporting, and training expectations that will require substantial institutional and federal government resources.

Drexel recommends that NIH:

- Avoid duplicative oversight processes that overlap with existing institutional review or compliance mechanisms.
- Consider the resource implications for institutions, including the need for additional biosafety professionals, administrative support, and IBC infrastructure.
- Conduct implementation impact assessments to evaluate the burden imposed on research institutions.
- Establish clear review pathways for:
    - Administrative changes
    - Minor amendments

    - Designated member review, in lieu of synchronous FCR, following federally mandated IACUC Designated Member Review process
    - Full committee review
- Permit institutions to leverage qualified staff review and administrative screening processes where appropriate.
- Provide supplemental funding opportunities or administrative supplements to support hiring biosafety personnel and expanding IBC infrastructure.

As federal agencies simultaneously advance other biosafety and DGOF-related initiatives, institutions will likely require significant investments in personnel and compliance resources to meet new expectations.

4. Reevaluate Public Transparency and Disclosure Requirements

Drexel supports appropriate transparency but believes additional safeguards are needed to prevent unintended consequences associated with public disclosure requirements.

We recommend that NIH:

- Reassess requirements for public posting of incident reports and committee records.
- Limit public reporting requirements to incidents with significant impacts to biosafety or public health.
- Permit redaction of:
    - Personal information
    - Medical information
    - Proprietary research information
    - Security-sensitive information
- Provide appropriate context when reporting incidents publicly.
- Consider aggregated reporting approaches for low-severity incidents and near misses.

Without appropriate context, public reporting may inadvertently generate confusion or mischaracterization of routine laboratory incidents that pose little or no public risk.

5. Clarify Definitions, Scope, and Policy Applicability

Several areas of the draft policy would benefit from greater detail and clarity to promote consistent implementation across institutions.

Drexel recommends that NIH provide additional clarity regarding:

- Definitions of covered biohazards and genetically modified organisms.
- Gain-of-function and related terminology.
- Applicability of policy requirements to NIH-funded and non-NIH-funded activities.
- Reporting thresholds and expected timelines.
- Available exemptions and exclusions.
- Expectations for institutional risk assessment processes.

Improved clarity would help institutions achieve consistent interpretation and compliance while reducing administrative uncertainty.

6. Preserve Effective Existing Biosafety Programs

Institutions have invested considerable effort in developing robust biosafety oversight programs under the current framework.

Drexel encourages NIH to:

- Build upon existing institutional biosafety systems rather than replacing effective processes.
- Maintain flexibility that allows institutions to tailor oversight to their research portfolios and organizational structures.
- Recognize the range (or breadth) of activities conducted at research universities, including research, teaching, clinical, and community-engaged programs.

7. Improve Incident Reporting Requirements

Drexel supports standardized reporting but believes additional clarification is needed.

NIH should:

- Develop a comprehensive reporting decision matrix.
- Provide clear definitions for:
    - Confirmed exposure
    - Potential laboratory-acquired infection

    - Containment failure
    - Containment loss
    - Minor spill
    - Near miss
- Distinguish events requiring:
    - Immediate NIH notification
    - IBC review only
    - Internal institutional management
- Clarify:
    - 24-hour notification triggers
    - 30-day reporting requirements
    - Expectations for incomplete investigations
    - Reporting responsibilities during uncertain or evolving situations

8. Provide Adequate Implementation Time

The proposed transition may require substantial institutional changes.

Drexel recommends:

- At least 12 months between publication of final guidance and full implementation.
- Availability of templates, guidance documents, and reporting systems prior to implementation.
- A phased adoption process that includes:
    - Program inventory
    - Training
    - Staffing adjustments
    - Assurance development
    - System modifications
    - Transition of existing protocols

- Preservation of existing renewal cycles where possible.

A phased implementation approach will facilitate compliance while minimizing disruptions to ongoing research.

Conclusion

Drexel University supports NIH's efforts to modernize biosafety oversight and strengthen stewardship of research involving biohazards. We encourage NIH to ensure that the final policy remains risk-based, clearly defined, operationally feasible, and supported by appropriate institutional infrastructure. Particular attention should be given to preserving exemptions for low-risk activities, clarifying scope and reporting requirements, establishing clear institutional accountability, protecting sensitive information in public disclosures, and providing sufficient implementation time for institutions to successfully transition to the new framework.

A policy grounded in proportional risk, clear guidance, and practical implementation will strengthen biosafety while supporting the continued advancement of biomedical research.

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definitions are too broad and go way beyond the intentions and scope of the intentions in this policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Use of Risk Groups should continue to be used even when genetically modified since they are rated by risk. Risk can be assessed and changed depending on genetic modification, but the assumption is that no modification will result in a dangerous gain of function or increase the risk assessment of the agent, so RG1 agents should not be included in the scope of this document.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: NIH-Policy-Comments.pdf

DGOF Listed Outcomes:

1. Enhance harmful consequences of a biological agent*
    a. The definition of biological agent is… “all biological agents and biologically derived toxins capable of causing death, disease, or harm in a human, animal, plant, or other living organism; deterioration of food, water, air, equipment, supplies, or material of any kind; or deleterious alteration of natural resources.”
    b. I feel like this should not include anything at RG1 given the definition of RG1 agents, “Agents that are not associated with disease in healthy adult humans. This group includes a list of animal viral etiologic agents in common use. These agents represent no or little risk to an individual and no or little risk to the community.”
    c. While I understand the concern about modification of agents, I feel like there should be more emphasis on the intent/purpose of the modification rather than the action of genetically modifying an agent itself. There are many standard and completely harmless genetic modifications that researchers make regularly to make the work feasible and efficient.
2. Disrupt beneficial immunity or immunization against the biological agent
    a. Of course, we do not want to disrupt immunity in any way, but there should be some room for nuance when it comes to model development since otherwise research is not able to move forward in many cases.
3. Confer prophylactic or therapeutic resistance or evade detection methodologies
4. Increase stability, transmissibility, or ability to disseminate the biological agent
    a. Of course, we do not want to increase transmissibility or stability, but there should be some room for nuance when it comes to model development since otherwise research is not able to move forward in many cases.
5. Alter host range or tropism of the biological agent
    a. Again, see above comments on model development for the purpose of research.
6. Enhance the host-population susceptibility to the biological agent
    a. Again, see above comment.
7. Generate or reconstitute an eradicated or extinct biological agent

Dangerous Gain-of-Function (DGOF) research

- There should be a clear list of exemptions including standard genetic modifications made to biological agents for the purpose of making research logistically feasible.

Grant Proposal Decision Path and Order:

- All federal grants should increase their award time to account for the extra burden of time and effort required to get through the new screening processes so that workflow is minimally impacted.
- Federal review should be a transparent process with a clear and consistent timeline so that researchers can ensure that they have funding to maintain their lab.
- Allocate extra money in each grant for the maintenance of new IRE committees and to compensate the extra work of the ICDGOF

List of Entities of Concern

- There should be a grace period built into this to consider ongoing research in collaboration with entities that might not have previously been of concern
- Depending on the severity of "concern", there should also be some flexibility on the extent of involvement with said entities

What is in Scope?

- Things that are non-pathogenic should not be in the scope of the guidelines
- Why is the breeding of transgenic animals a concern? Or should it be the breeding of
- 'Plasmids' is too generic – the type of plasmid should be specified
- Why are all, "cells, viruses, or organisms that have been genetically modified," considered a biohazard? I would think that this should be more specific about whether these cells, viruses, etc can cause harm AND are genetically modified. It should also take into consideration what kind of genetic modification has been introduced.
- Why are well-characterized cell lines in scope?

The definition of genetic modification should include a list of common laboratory modifications that do not confer any harmful phenotypes

Incident Reporting:

Extent of "first aid" treatment required regarding RG1/BSL-1 incidents should be specified since some BSL-1 labs have desks in the lab and could get unrelated low risk injuries

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Parasitology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I do not believe the scope of the new policy is appropriate for the goal of the modernization of the policy. My interpretation of the proposed changes to the scope is that it would actually widen the scope to include things that are not actually a biohazard. According to wording of point 2 of the scope, any genetically modified mouse line could fall under this or any non-infectious bacterial expression vector could fall under this. Furthermore, the wording under gene modification referring to "have the potential for one or more cycles of replication in a cell; or can be transcribed or translated" could again now include non-biohazard research. For example, under this it could be assumed that expressing a plasmid in competent cells is now considered a biohazard. I understand there is a fine line between keeping the scope broad to avoid it being too narrow, however, as it reads now the scope is too narrow and should really be clarified.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I do not see any issues with this.

3. Continued utility of Risk Groups: I do not see any issues with this.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Before pushing voluntary compliance, the scope should really be clarified.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I appreciate the effort to streamline incident reporting and meeting minutes via a template. I am supportive of these templates and that they need to be public facing for transparency as they would create consistency with reporting. However, I am against that PI information would be public facing and not redacted. I understand having accountability for incidents, however, a policy like this will guarantee that PI's no longer report incidents for fear of backlash. The policy should not be publicly doxxing PIs for reporting incidents, that information should be redacted from public facing documents.

RE: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards

To Whom it May Concern,

The University of Oregon (UO) appreciates NIH's efforts to modernize and strengthen biosafety oversight and supports the overall goals of enhancing biosafety, transparency, accountability, and public trust in the biomedical research enterprise. We agree that biosafety oversight frameworks should evolve alongside advances in biotechnology and increasingly complex research environments.

At the same time, we encourage NIH to provide substantially greater implementation guidance, clearer policy language, and a more realistic implementation timeline before finalizing the policy. Several aspects of the draft would create significant operational and administrative challenges for institutions without corresponding resources, staffing support, or implementation mechanisms. Our comments focus on the practical requirements for implementing the proposed framework at UO.

1. Clarify Applicability to Existing Research and Expectations for Institutional Assurances

One of our most significant concerns is the transition of ongoing research to the new policy. The draft policy states that it would apply to all existing awards and agreements as of the effective date and would prohibit covered research from being conducted until NIH has approved the institution's written Biosafety Assurance submitted through its Authorized Organizational Representative (AOR).

It remains unclear whether an institution must review and revise all existing Institutional Biosafety Committee (IBC) registrations and approvals prior to submitting such an assurance for NIH approval. If full compliance requires reassessment of all currently active protocols before the effective date, institutions will face a substantial implementation burden that is not adequately addressed in the proposal.

For institutions such as the UO, where IBC review processes, registration forms, and risk assessment procedures were developed under the existing NIH Guidelines framework, determining compliance with a fundamentally revised policy could require extensive protocol review and modification. We recommend NIH explicitly state:

- Whether existing IBC approvals remain valid until their next scheduled review;
- Whether institutions may implement the policy prospectively for new submissions while transitioning existing protocols over a defined period;
- What minimum actions are required before an AOR may submit an institutional Biosafety Assurance for NIH approval; and

OFFICE OF THE VICE PRESIDENT FOR RESEARCH AND INNOVATION

1266 University of Oregon, Eugene OR 97403-1266

T (541) 346-2090 **F** (541) 346-2023 http://uoresearch.uoregon.edu

The University of Oregon is an equal-opportunity institution committed to cultural diversity and compliance with the Americans with Disabilities Act.

- Whether institutions will be afforded a phased implementation process, including transition arrangements for institutions awaiting NIH approval of their Assurances.

Given the breadth of changes proposed, the six-month implementation period appears insufficient, particularly if institutions must reassess active research portfolios before certifying compliance. We recommend an implementation period of at least 12 months after complete operational guidance and Assurance procedures are available, with a phased transition of up to 24 months for currently approved protocols.

2. Better Align Institutional Responsibilities with Available Resources

The draft policy would expand or modify existing institutional biosafety responsibilities and introduce additional implementation requirements. In addition to requiring institutions to ensure appropriate training regarding laboratory safety and implementation of the policy, the draft assigns responsibilities to IBCs and biosafety personnel, including:

- Periodic review of approved research;
- Development and maintenance of emergency response plans;
- Incident review and documentation;
- Implementation of revised public posting requirements for meeting minutes and incident reports;
- Expanded record-keeping obligations;
- Additional risk assessment activities; and
- Potentially broader oversight responsibilities under the expanded scope of covered biohazards.

At the UO, implementation would rely on one Biosafety Officer within Environmental Health and Safety and on IBC members who already have substantial responsibilities. Revising active registrations, institutional procedures, training materials, and public-facing resources within six months would place substantial demands on this existing capacity. Even where obligations already exist, changes in scope, documentation, reporting, and public posting would require substantial institutional work. The draft does not provide sufficient operational guidance regarding staffing, implementation funding, or the resources needed to support these requirements.

We recommend NIH:

- Provide detailed implementation guidance documents before policy implementation;
- Develop standardized training materials that institutions may adopt;
- Create model templates and best-practice resources beyond those currently proposed;
- Consider supplemental implementation funding opportunities; and
- Establish a proposed timeline for a transition period during which institutions can develop the necessary infrastructure.

We request that the final policy clarify how responsibilities should be allocated among the institution, the IBC, the BSO, and PIs, including which activities may be delegated and what documentation is required to demonstrate appropriate oversight. The final policy also needs to

distinguish de novo protocol renewal from periodic compliance monitoring, and clarify the expected frequency, acceptable delegated processes, and documentation for the latter.

It would be beneficial if the NIH would provide practical examples and eligibility criteria for delegated review of well-characterized, low-risk research so that institutions can apply the policy consistently and proportionately.

3. Provide Greater Specificity Regarding Training Requirements
The policy requires institutions to ensure appropriate training for IBC members, Biosafety Officers, investigators, and laboratory personnel, and assigns PIs responsibility for training personnel under their supervision. However, the draft does not specify sufficient operational detail regarding:

- Minimum training expectations;
- Frequency of required training;
- Acceptable training formats;
- Required documentation standards; or
- Whether NIH will provide nationally standardized curricula.

Without such guidance, institutions may develop substantially different interpretations and implementation approaches, undermining the goal of consistency across the research enterprise. We strongly encourage NIH to provide detailed implementation standards and standardized training resources before compliance is required.

4. Recognize the Significant Administrative Revisions Required at Institutions
While the draft policy is intended to modernize oversight, implementation will require extensive revision of institutional processes and documentation.

At the UO, the existing IBC registration process already incorporates a robust risk assessment framework. Nevertheless, substantial revisions would be needed to:

- Modify and restructure IBC registration forms;
- Update biosafety manuals and program documentation;
- Revise institutional policies and procedures;
- Update investigator guidance materials;
- Develop new training programs;
- Create new incident-management and reporting workflows; and
- Adapt and maintain public-facing resources to meet revised transparency requirements, including changes to existing meeting-minutes posting practices.

These efforts represent a major institutional undertaking that extends beyond simple policy adoption. NIH should acknowledge the scale of these changes and provide both implementation guidance and sufficient time for institutions to make the necessary operational modifications.

5. Request Additional Guidance Before Policy Becomes Effective

The draft policy states that NIH intends to provide supplemental implementation materials and guidance resources. We appreciate NIH's existing explanatory resources and request additional operational guidance addressing unresolved implementation questions.

Because many key operational details remain unclear, institutions cannot accurately estimate compliance obligations, staffing needs, training requirements, or implementation costs. We therefore recommend that NIH:

- Release draft implementation guidance concurrently with the policy prior to finalization;
- Expand FAQs to address the transition of active protocols, Assurance submission and approval, delegated review, training documentation, and reporting and redaction procedures;
- Conduct webinars and stakeholder engagement sessions focused on implementation;
- Establish a formal transition process; and
- Set the effective date to allow at least 12 months of preparation after complete operational guidance and Assurance procedures are available, with a phased transition of up to 24 months for currently approved protocols.

We support transparency and request clear guidance on permissible redactions and the preparation of public-facing records that protect personal privacy, proprietary information, and security-sensitive details.

The University of Oregon supports NIH's goal of strengthening biosafety oversight and appreciates the agency's investment in modernizing a framework that has served the research community for decades. However, the current draft raises significant concerns regarding implementation feasibility, administrative burden, institutional resource requirements, and the ambiguity surrounding compliance obligations for ongoing research activities.

We respectfully request that NIH provide greater clarity regarding expectations for existing protocols, expand implementation guidance, and adopt a longer and more phased implementation timeline. These modifications would better enable institutions to achieve the policy's important biosafety objectives while maintaining effective and sustainable research oversight programs.

Sincerely,

Bethany Jenkins
Vice President for Research and Innovation

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Physiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft NIH biosafety policy significantly expands the scope of the current NIH Guidelines on Research Involving Recombinant or Synthetic Nucleic Acid Molecules. As a result, Institutional Biosafety Committees (IBCs) will be responsible for oversight and reporting for a much broader range of research.

The key concern over this expansion in scope is that it will likely result in IBCs devoting more bandwidth to low-risk research activities, leaving less time to evaluate higher-risk research. Institutional policies already often empower IBCs to exercise oversight of research involving the types of biohazards included in the draft NIH biosafety policy. However, the draft policy would formalize this oversight and potentially increase administrative burden by requiring reportable and auditable protocol reviews and incident reports, even for low-risk research activities.

While the option for delegated review of lower-risk research somewhat offsets the administrative burden of the new policy, NIH could further reduce the administrative burden without significantly compromising safety by making a small number of changes to the policy, such as 1) extending IBC protocol approval to five years to match the duration of most NIH research project grants; 2) removing the requirement to publicly post incident reports for lower-risk incidents that do not significantly endanger public health; and 3) generally streamlining reporting requirements for low-risk and routine research activities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed policy outlines three tiers of covered research based on risk. However, the regulatory oversight required under the draft policy is broadly similar among the tiers. All research protocols, regardless of risk tier, must be evaluated by the IBC and included in meeting minutes, although the lowest risk tier allows delegated review. Similarly, safety incidents during research at all risk tiers must have a report published on a public-facing webpage, although the lowest risk tier does not require reporting to the NIH.

While it is a strength of the policy to divide research into tiers of risk, the policy could be improved by streamlining lower-risk research oversight. This should include removing the requirement of posting low-risk incident reports to a public-facing website. This requirement does not improve safety, but it discourages reporting of incidents and places potentially sensitive information at risk. Further feedback about this requirement is given in the response to question 5.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The level of detail included in the Required Template for Meeting Minutes and the Required Template for Reporting Incidents and Accidents, in combination with the requirement that they are posted to a publicly viewable webpage, compromises research and information security, conflicts with federal research security regulation, and provides no meaningful benefit to laboratory safety. It would create a standardized and searchable set of data across institutions detailing experimental procedures, agents and species used, and where they are kept.

Federal policies and regulations require institutions to safeguard information about potentially dangerous agents and provide oversight of their storage and record-keeping. For example, 42 CFR § 73.17 requires that records and databases of select agent inventories have controlled access. The standardized meeting minutes template conflicts with this and other regulation by creating a public list of agents and locations along with details about security and containment. Allowing specific information to be redacted from the meeting minutes will not resolve this issue, as it is unreasonable to expect IBC members to reliably judge which information may be potentially sensitive.

Beyond the information about select agents and potentially dangerous material, the detail requested in the meeting minutes template effectively creates a full list of protocols on an institution's website. This significantly compromises research security by providing a road map for competing laboratories to reconstruct unpublished work. In particular, researchers in countries of concern could use this information to gain an advantage over the U.S.

The information required in the Draft Incident Reporting Template creates a clear conflict between safety and personal privacy that likely undermines the policy's effectiveness. The template requires including the name of the Principal Investigator for the research conducted while the individual(s) involved in the incident are identified only by position title rather than by name. However, for many researchers in academic laboratories with a small number of staff, deducing an individual from their title and PI name is often trivial. As a result, online incident reports will create a public record detailing incidents that can with minimal effort be traced to the individual(s) involved.

One concerning outcome of this policy is that it encourages laboratory staff and PIs not to report biosafety incidents. If either the staff member or the PI is concerned about the potential consequences of making a laboratory accident a matter of public record, they may conceal critical information about the accident from the IBC. The draft biosafety policy provides no opportunity for anonymous reporting of safety concerns or incidents, so every report requires the release of potentially identifying information.

Both the Required Template for Meeting Minutes and the Draft Incident Reporting Template create public records of detailed information about animal research. Research involving animals is sensitive and researchers targeted by activist groups often receive harassment and threats of violence. The incident report template makes information about which researchers handle which animal species publicly available, creating a map for activist groups to target researchers.

It is unclear how requiring institutions to publicly post the details required in the meeting minutes and incident report templates would advance laboratory safety. However, for the reasons outlined here, this requirement conflicts with research security, exposes sensitive information, and weakens oversight of laboratory safety reporting. NIH should amend the proposed policy so that requirements to publicly disclose information do not conflict with federal research security regulations and limit detailed information about research protocols, agent storage, animal research, and researcher identities. Additionally, the NIH policy should facilitate anonymous incident reporting to IBCs so that safety issues can be addressed without placing individuals at risk.

6. Other feedback relevant to this resource: NIH should provide examples of the level of detail required (and not required) for protocol reviews for both high-risk and low-risk categories of research, including a rubric for determining which risk category an investigator's research falls under.

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical and infectious disease research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Scope:
For the purpose of the scope of this Policy, research involving biohazards is defined as research involving known or potential risk to human health and any of the following:
-the use of biohazards within this context is ill-defined, too broad, and requires more precision (i.e., healthy human adults (BMBL), healthy human children, toddlers and infants, immunocompromised human adults, children, toddlers and/or infants, drawing a blood sample as part of an IRB and IBC research protocol (is it now covered under the OSHA rule, the NIH, the BMBL or any combination thereof)
-is it the intent of the policymakers to isolate human health risk and research to the NIH and OSHA, agricultural health risk and research to USDA-APHIS and BRS, and select agent risk and research to the CDC?
-would it not be easier to use the existing OSHA, FSAP and USDA-APHIS frameworks, since by the proposed definition of biohazards, the current policy scope is redundant and will now cause confusion amongst researchers and compliance offices?

Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
-concur, however as previously stated this aspect of the policy, as is, becomes redundant when compared to the FSAP regulations
-what immune status of "humans"?
Cells, viruses, or organisms, other than plants, that have been genetically modified;
-is "organisms" the intended target word, as from a biological perspective it will include humans, animals, fungi, parasites, etc. (except plants)
-are "organisms", as outlined, all biohazardous
-natural or synthetic genetic modification
Toxins, prions, and other self-aggregating proteins; or
-chemical and toxins of biological origins?
Cells or organisms, other than plants, containing 1, 2, or 3 above.
-see previous statements

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Research with wild type or genetically modified RG2 biological agents for which lower containment is requested vs. Research involving RG2 wild type biological agents
-the first requires full IBC review prior to initiation and the second can be by delegation prior to initiation
-recommend that they should be combined and delegated review should be an option available to the local IBC
-if they cannot be combined, what is the reason?

3. Continued utility of Risk Groups: Both should be used when generating a biological risk assessment, as their definitions are different but complementing.
-a RG1 agent, which is not covered under this policy and when grown in large batch volumes, should be done so at a higher BSL due to more stringent containment requirements

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): A mechanism of public/community recognition, of the institution, by the NIH.
An tiered implementation procedure that is tailored to the institution with the assistance of the NIH.
An NIH pre and post implementation assessment.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: What level of detail is required for the Training and Risk Assessment portion of the Meeting Minutes template? An example or rubric of what the expectations are would go a long way in preventing a cycle of submissions and resubmissions.

Forms either need to be fillable or with an expanded narrative section or both. An example or rubric of what the expectations are would go a long way in preventing a cycle of submissions and resubmissions.

6. Other feedback relevant to this resource: Implementation timeline should either be extended, tiered, tailored to the individual institution or some combination thereof. It is unrealistic and, if enforced immediately, will result in confusion, deterioration of trust and/or failures of continued compliance amongst compliance offices, researchers and institutions.

An immediate announcement regarding continued institutional operations based on current NIH Guidelines or the revised policy following the termination of the comment period. It seems unreasonable for institutions to begin a laborious process/program improvement task, only to have to change it again due to policy revisions.

A tiered implementation rubric and milestone implementation plan/guidance based on institution size (i.e., number of covered laboratories, BSL, agent types, etc.), levels of funding, types of research, etc. would be helpful in streamlining implementation and providing markers for institutional leadership and the NIH regarding implementation status updates.

386. The Manton Center for Orphan Disease Research at Boston Children's Hospital

I am responding: On behalf of an organization

Name: Alan H. Beggs, PhD

Name of Organization: The Manton Center for Orphan Disease Research at Boston Children's Hospital

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Genetics and genomics of pediatric disease

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The current definition of "Genetic modification" is inaccurate and inappropriate. As proposed is specifies:

Genetic modification:
The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
Have the potential for one or more cycles of replication in a cell; or
Can be transcribed or translated

The final criterion "Can be transcribed or translated> should be eliminated because that includes many transient assays that do not lead to genetic modification and would inflate the scope of experiments tremendously, leading to undue regulatory burden without any additional benefit.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

I am responding: On behalf of myself

Name: Kara Drolet

Name of Organization: OHSU

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Apparent lack of exemptions: It is recommended that NIH maintain the previously established categories of exempt research. NIH describes the purpose of the modernization as expanding oversight to biohazards while "removing red tape for low-risk research" and specifically asks commenters whether the proposed tiered oversight is appropriately calibrated to risk and administrative burden.

Exempt from IBC oversight is not synonymous with exempt from safe laboratory practice. Rather, it represents a determination that the incremental safety benefit of mandatory IBC oversight does not justify the administrative burden for a defined class of low-risk research. Currently exempt research was previously determined by NIH, following notice and opportunity for public comment, not to present a significant risk to health or the environment.

Review requirements for primary cell lines/well-characterized cell lines: As written, "may be contaminated" could be interpreted to include virtually any primary human or animal cells (including any research involving NHP cells or tissues) for which the infectious-agent status of the source has not been comprehensively established.

NIH should define "adventitious agent," establish a risk-based threshold for determining when contamination is reasonably anticipated, and clarify whether donor screening, testing, source information, or other documentation can establish that primary cells do not fall within this category. The Policy should also clarify its application to commercially obtained cells, repository specimens, patient-derived cells, and primary animal cells and provide examples of included and excluded materials. A merely theoretical possibility of contamination should not independently trigger IBC oversight; the definition should be tied to a known or reasonably anticipated potential hazard to human health. Clear criteria are necessary to avoid additional administrative burden by unnecessarily expanding IBC oversight beyond research presenting a meaningful biosafety risk

The Policy does not provide sufficiently objective criteria for determining when a cell line qualifies as

well-characterized, creating the potential for inconsistent interpretations among investigators, biosafety professionals, and IBCs. NIH should specify what level of information regarding identity, provenance, biological characteristics, and adventitious-agent testing is necessary; whether established commercially available or widely used cell lines may be presumed to satisfy the definition; and how primary, immortalized, genetically modified, and patient-derived cells should be treated. NIH should also provide examples of included and excluded cell lines. Because this determination may affect the scope and level of institutional oversight, a clear, risk-based definition is necessary to ensure consistent implementation and avoid additional administrative burden by unnecessary review of research that does not present a meaningful biosafety risk.

Review requirements for self-aggregating proteins: IBC review is appropriate for the review of research involving prions or biospecimens identified to be from a person or animal known to have a prion-based disease. However, the term self-aggregating is not sufficiently defined to permit institutions or investigators to determine consistently if every protein that happens to aggregate or contributes to an aggregation-associated human disease, such as ALS, is also covered.

Protein aggregation alone does not necessarily establish a meaningful biosafety hazard. NIH should clarify whether “other self-aggregating proteins” is intended to encompass proteins with prion-like, seeding, propagation, transmissibility, pathogenic, or other specified hazard characteristics rather than any protein capable of aggregation. The definition should identify objective criteria and provide examples of both covered and excluded materials.

Human subjects' studies requiring IBC review:
Section IV-2 outlines the only clinical research provision and specifically identifies IBC review for biohazards that shed, replicate, integrate, require higher-risk manipulation, or involve RG2 or higher wild-type agents. There is no discussion of other genetically modified agents being used in clinical research, such as plasmids or RNA, and no discussion of exemptions. Given the federal initiative to streamline clinical trials: https://www.hhs.gov/press-room/hhs-launches-clinical-trials-reform-initiative.html, additional administrative burden should not be introduced by expanding IBC oversight in the clinical research arena.

The Policy should also exempt any covered clinical research studies from mandatory three-year de novo IBC review or permit an administrative continuation process confirming that no material changes affecting biosafety have occurred. Full IBC review should be required only for clinical research presenting local biosafety risk, where there may be questions regarding product handling and possible shedding. This approach would maintain appropriate biosafety oversight while reducing unnecessary regulatory burden

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: It is recommended that NIH revise the approach to public posting of incidents so that detailed incident reports are submitted to NIH but are not routinely required to be posted publicly in their entirety. Alternatively, NIH could provide a template for public posting of standardized, de-identified high level summary information of incidents that might include root-cause categories and corrective actions. NIH could separately require disclosure of additional information when a particular incident presents a compelling public health or safety interest.

This approach balances transparency objectives with the equally important need to preserve a just, non-punitive reporting culture in which researchers and staff are encouraged to report incidents, near misses, and potential safety concerns promptly and completely. It also provides protections for researchers that are increasingly threatened or harassed due to the tools or subject matter of their research.

Importantly, NIH would receive the information necessary to evaluate significant incidents, institutional responses, and compliance. The distinction would therefore be between information necessary for regulatory oversight and information necessary for public transparency, rather than assuming that the same level of detail is needed for both purposes.

6. Other feedback relevant to this resource: Overall implementation and requirement for institutional assurance: A six-month implementation period is insufficient given the breadth, complexity, and institutional impact. Revising electronic systems to accommodate the new regulations is a significant challenge that will likely prevent many institutions' ability to meet this timeline. Additionally, updating policies and procedures and ensuring that researchers have the training they need to understand the new requirements, including newly covered areas of research, will require additional time. The time required to identify newly covered research is one reason why it is critical for entities to be held to realistic and achievable implementation timelines.

NIH should provide a detailed description of the required elements of an institutional assurance and publish accompanying implementation guidance before policy adoption, including model assurance language, implementation templates, and sufficient lead time for institutions to develop. Administrative burden should be kept in mind in considering required elements.

Delegated review: It appears that it is the intent that an initial protocol may qualify for delegated review if it only contains work identified as eligible for delegated review under Section IV-3. Clarified wording is recommended "for minor amendments to previously approved submissions or for initial research protocols"

There are inconsistencies between the descriptions of research that require committee review (Section IV-2) and research that may be eligible for delegated review (Section IV-3). A potential clarification is to state that "Where research is described by both Section IV-2 and Section IV-3, research meeting all applicable criteria specified in Section IV-3 may undergo delegated review unless another characteristic of the research independently requires review under Section IV-1 or IV-2. A delegated reviewer may refer any submission to the full IBC when warranted based on the risk assessment."

Subject: Comments on NOT-OD-26-112 Request for Information: Draft NIH Biosafety Policy for Research Involving Biohazards

Submitted electronically via NIH comment form at https://osp.od.nih.gov/comment-form-draft-nih-biosafety-policy-for-research-involving-biohazards/

Dear National Institutes of Health (NIH) Office of Science Policy (OSP),

Advarra, Incorporated (Advarra) is a U.S.-based company that provides institutional review board (IRB) and institutional biosafety committee (IBC) research review and oversight services, compliance and quality assurance services, inspection readiness and auditing, and technology platforms in support of clinical research operations. In particular, Advarra externally administers IBCs for over 1,500 research sites, including large academic medical centers, small academic institutions, privately owned clinical research sites, biotech companies, and drug manufacturers. With our experience in applying biosafety standards to the clinical realm, Advarra has published on the evolution of NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines) as it relates to clinical research as well as the applicability of Food and Drug Administration (FDA) Guidance documents to IBC review.[1-5]

Advara applauds the NIH's efforts at modernizing biosafety oversight, including the agency's commitment to soliciting input from stakeholders representing the public and the biosafety community. We are pleased to provide comments and suggestions on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice No. NOT-OD-26-112) issued by the NIH in August 2026.

As a general comment, we note there are potential gaps and ambiguities in the draft policy regarding clinical research. Specifically, Section IV-2 outlines criteria for higher risk clinical research that requires IBC review and approval prior to initiation; however, the draft policy does not explicitly address lower risk clinical research. This absence of granularity regarding lower risk research could be interpreted in one of two ways: Either research involving biohazards (i.e., lower risk clinical research) will not be covered by the draft policy's IBC requirement, or most clinical research involving lower risk biohazards could be reviewed via IBC subcommittee / designated member review (DMR) or could be determined to be exempt from IBC review.

The latter could be very helpful, as DMR would allow flexibility and streamlining of the review process based on a given research study's level of risk. However, those relying on the former interpretation may

Copyright 2026 Advarra, Inc.

assume most research involving biohazards would not require IBC review, which could lead to significant safety and regulatory oversight gaps in the clinical setting.

A recent peer reviewed survey article suggests biosafety professionals overwhelmingly support the unique role of IBCs in addressing biosafety considerations that are not fully encompassed by FDA for regulatory oversight. Greater than 90% of respondents stated that the guidance provided by IBCs to research personnel is important for product handling procedures, training and education, as well as needlestick and exposure prevention. While the article's authors acknowledge their limited pool of survey respondents as a potential source of bias in their methodology, we feel strongly that even if the data were obtained from a larger survey group, the results would reach similar conclusions.[6]

Our observations and comments below provide suggestions for the NIH to consider when revising the draft policy for research involving biohazards. Where we suggest specific content revisions, we use ***bold-italicized font*** to indicate new or revised text.

1. Scope of research covered by the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.

Observation 1. While the "Scope" discussion in Section II of the draft policy explicitly covers certain aspects of clinical research in laboratory settings involving biohazards, other aspects of clinical research appear to be only partially addressed or missing. This limited description of the research covered under the draft policy could lead to an inadvertent gap in safety and regulatory oversight for clinical research. For additional information on this concern, please see our general comment, which begins on p1 of this response document.

We also note that non-scientific regulatory personnel at pharmaceutical companies which also collaborate with the NIH routinely misinterpret the current NIH Guidelines as not applying to RNA-based technology, specifically misunderstanding the "can be translated or transcribed" criteria in Section III-C-1-2-d. This also creates a gap in safety and regulatory oversight for clinical research, as RNA technology can be used both for low-risk applications (e.g., mRNA-based vaccines) as well as higher risk activities (e.g., guide RNA for CRISPR-based gene editing). This higher risk category would also include replicons / self-replicating RNAs, which can potentially cause prolonged gene expression, and mRNA-encoded hazardous products (e.g., toxins, oncogenes, prions, or other self-aggregating products capable of causing neurodegenerative disease).

Suggestion 1. Because of the exposure risks to research participants, we suggest NIH explicitly state that IBC review is required for products covered under the scope of the policy when administered to one or more human research participants. This would include products containing nucleic acid molecules that have either undergone genetic modification (e.g., viral vectors, gene-modified cellular therapies, etc.) or are capable of introducing genetic modifications (e.g., stable gene integration, gene editing, epigenetic changes, etc.) into human research participants, as outlined in the draft policy's definitions.

We also recommend revising the definition of "genetic modification," in Section II "General Definitions," to clarify that the definition applies to RNA-based technologies. See below for specific revision recommendations, where we suggest adding additional information to Section II "Scope" and "General Definitions":

Scope

For the purpose of the scope of this Policy, research involving biohazards is defined as research involving known or potential risk to human health and any of the following:

1. Wild type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;
2. Cells, viruses, or organisms, other than plants, that have been genetically modified;
3. Toxins, prions, and other self-aggregating proteins; or
4. Cells or organisms, other than plants, containing 1, 2, or 3 above.

[NEW] IBC review is required for products covered under the scope of the draft policy when administered to one or more human research participants.

[text omitted]

General Definitions

[NEW] Genetic modification:

- The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria:
    - Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or
    - Have the potential for one or more cycles of replication in a cell; or
    - Can be transcribed or translated ***(e.g., RNA-based technology)***; or
- The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means.

Please also refer to Observation 6 / Comment 6 in this document related to the assignment of risk with clinical research and IBC review.

Observation 2. Section IV "Categories of Oversight for Research Based on Risk" states certain research associated with higher levels of risk or uncertainty must be reviewed and approved at the federal level by NIH. In this section, the draft policy also states that such research must also be reviewed and approved by the IBC. However, in Section IV-1 of the draft policy, we note a potential omission or inconsistency in the described approval requirements. Specifically, the first sentence of Section IV-1 describes review and approval for higher risk research to be obtained from NIH alone. Later, in the last sentence of Section IV-1, initiation of research may proceed from both NIH and the IBC. Given Section IV's statement that review and approval must be obtained from both NIH and the IBC, we are unsure why "IBC" is omitted.

Suggestion 2. We suggest NIH clarify if IBC review and approval does or does not apply in Section IV-1. If the "IBC" omission in the first sentence is inadvertent, we propose revising the first sentence in Section IV-1 as follows:

> ***[NEW]*** Review and approval for determination of appropriate containment and biosafety practices and procedures must be obtained from NIH ***and the IBC*** for higher risk research including:

Observation 3. In Section IV-2 of the draft policy, we note that the clinical research elements included in the bulleted list reflect higher risk products but are not labeled as such.

Suggestion 3. For improved clarity, we suggest NIH revise the sixth bullet in the Section IV-2 list to add "Higher risk" in front of "clinical research":

> - ***[NEW] Higher risk*** clinical research involving deliberate administration to one or more human research participants of the following biohazards:

Observation 4. In the current NIH Guidelines, Section III-C-1-2-a pertains to clinical research involving recombinant or synthetic nucleic acid molecules that "Contain more than 100 nucleotides." This detail is quite helpful for IBCs, as there is a large volume of low-risk clinical research involving agents under 100 nucleotides that would not benefit from IBC review. However, the draft policy does not include information on agents below 100 nucleotides.

Suggestion 4. In Section II "Scope," we recommend the draft policy include an exemption for clinical research involving nucleic acid molecules under 100 nucleotides in length that are not capable of creating durable genetic modification, including genomic integration or gene editing, and do not encode toxins, oncogenes, prions, or self-aggregating products capable of causing neurodegenerative

disease in human or animals. We propose the following language for NIH's consideration, which we suggest could be included as new content in Section II "Scope" situated after the current penultimate sentence "Based on . . . oversight as described in Section IV.":

> ***[NEW] Exempt from this policy is research involving the delivery to one or more human research subjects of nucleic acid molecules, that contain under 100 nucleotides and:***
>
> - ***Are not capable of creating durable genetic modification, including genetic integration or gene editing, and***
> - ***Do not encode functional portions of toxins, oncogenes, prions, or self-aggregating products capable of causing neurodegenerative disease in humans or animals.***
>
> ***The exemption does not apply to use of viral vectors, gene modified microorganisms, or other agents covered by this policy. Delivery of guide RNA for gene editing requires IBC review and is not covered under this exemption.***

Observation 5. The current NIH Guidelines apply to NIH-funded or -supported research and also extend to research collaborations. We respectfully request NIH to reconsider the draft policy's narrower approach and expand it to include research conducted or collaborated with non-federally funded organizations. We note this because there is currently no requirement under FDA regulations at Title 21 to require biosafety review for clinical research involving biohazards. An external obligation or similar mechanism (like the current NIH Guidelines) for research collaborations is valuable to help ensure that the entire research community applies appropriate safeguards and oversight to this type of high-risk research regardless of a project's funding source. In addition, since the draft policy has expanded beyond the current NIH Guidelines' scope of use with recombinant or synthetic nucleic acid molecules, we recommend the draft policy incorporate revised language addressing this type of research.

Suggestion 5. In the draft policy's Section II "Compliance and Enforcement," we suggest NIH include wording similar to that provided in the current NIH Guidelines Section I-C-1-a-(2) "General Applicability." We suggest the following proposed language be added as the new second paragraph in "Compliance and Enforcement":

> ***[NEW] This policy applies to research that involves testing in humans of biohazards, including materials capable of genetic modification covered under the scope of this policy and developed with NIH funds, if the institution that developed those materials sponsors or participates in those projects. Participation includes research collaboration or contractual agreements, not only provision of research materials.***

2. Structure of tiered oversight (i.e., Federal, institutional, and investigator), including appropriateness in terms of calibration to risk, accountability measures, transparency, and streamlining of administrative burden, etc.

Observation 6. The level of review and approval by the IBC required for clinical research is not solely delineated based on risk in the draft policy, which presents potential inconsistency with the risk-based approach used throughout the rest of the draft policy to categorize and delineate types of research that would or would not require IBC review. Specifically, we notice this inconsistency in Section IV-2 of the draft policy:

> - Clinical research involving deliberate administration to one or more human research participants of the following biohazards:
>   - Products that are capable of shedding, replicating, or integrating.
>   - Products that require higher risk manipulations (e.g., aerosolization, bladder infusions).
>   - RG2 or higher wild type biological agents (e.g., challenge experiments for medical countermeasures).
>
> Clinical research cannot be initiated until IBC, and all other applicable institutional and regulatory authorization(s) and approvals have been obtained.

Suggestion 6. We suggest NIH revise the draft policy to add information regarding clinical research risks and provide the following revised language for NIH's consideration. We propose placing this language in Section IV-2 after the sentence "Clinical research cannot be initiated until . . . have been obtained.":

> ***[NEW] Clinical research involving lower risk agents and manipulations may be reviewed as outlined in Section IV-3. Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members. Clinical research falling into this category would include agents that have undergone genetic modification rendering them unlikely to cause human disease and/or are not capable of shedding, replicating, gene editing, or genomic integration.***
>
> ***When the level of IBC review is not clearly outlined in this policy, refer to Section V-D. Requirements and Considerations for Risk Assessment of Manipulations of Biohazards.***

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

Observation 7. Risk group classifications (such as those in the current NIH Guidelines Appendix B - Table 1 "Basis for the Classification of Biohazardous Agents by Risk Group") are an essential first step in the risk assessment process, and we encourage NIH to retain this approach in the policy. However, we note that the current risk group classification criteria in the current NIH Guidelines Appendix B - Table 1 are inadequate for agents which are not microorganisms (e.g., biological toxins, gene editing technology, gene drives, or any recombinant or synthetic nucleic acid molecules which are not in microorganisms, or use of lipid nanoparticles to deliver biological materials).

Suggestion 7. We suggest NIH include in the draft policy the Appendix B - Table 1 content from the current NIH Guidelines, potentially placing it in the draft policy's Section V-A after the first paragraph. We also recommend updating these risk group classifications to reflect the types of agents utilized in biomedical research beyond wild type microorganisms. For assistance regarding risk classification of agents that are not wild type organisms, NIH might consider adapting the methodology from the Rand Corporation's *A Standardized Framework for Assessing High Risk Life Sciences Research* Appendix A, "Detailed Methodology for Assessing Laboratory Risks Versus Research Benefits."[7]

4. Effectiveness of compliance and enforcement mechanisms for ensuring biosafety, including strategies for encouraging voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions), and addressing any biosecurity challenges.

Observation 8. The draft policy appropriately identifies IBCs, IRBs, and institutional animal care and use committees as important components of the biomedical research regulatory oversight system. We suggest the final biosafety policy build on that concept by explaining how IBC and IRB review should be aligned across internal and external review committees when research involves the administration or other clinical use of a biohazardous product.

This alignment is especially important for FDA-regulated investigations involving products that may shed, replicate, or integrate; contain genetically modified material; require higher risk procedures; or otherwise create biosafety risks for research participants, healthcare personnel, laboratory staff, or the surrounding community.

Section IV-2 of the draft policy identifies as requiring prior IBC review clinical research involving products capable of shedding, replicating, or integrating; products requiring higher risk manipulations; and certain wild type biological agents. These provisions are important. However, the draft policy addresses research primarily through NIH funding requirements and institutional assurances. As a result, it may not consistently apply to FDA-regulated clinical investigations involving biohazards conducted by sponsors or institutions that do not receive NIH funding. Further, confining rigorous federal biosafety mandates to NIH-funded or -supported research alone creates a patchwork system of oversight, leaving privately funded, industry-sponsored, or foundation-sponsored research operating under inconsistent standards. To truly safeguard public health and national biosecurity, the final policy

should establish a universal baseline for all biomedical research involving biohazards nationwide, aligning federal expectations across the entire research ecosystem.

This approach creates a gap in oversight of research involving biohazards. FDA's investigational new drug regulations require IRB review and approval for clinical investigations, but 21 CFR part 312 does not expressly require a sponsor or investigator to identify, obtain, or maintain IBC approval when an investigational product or protocol presents a biosafety concern. A clinical investigation involving biohazards and human participants could therefore be subject to FDA requirements for IRB oversight without also being subject to the current NIH IBC framework if the institution does not receive NIH funding or otherwise fall within the scope of the draft policy.

Suggestion 8. NIH could use this draft policy development process to work with FDA on a consistent framework for coordinating IRB and IBC oversight of FDA-regulated clinical research involving biohazards.

One possible model is found in 21 CFR 361.1, which governs certain types of radioactive drug research. That regulation requires both:

1. Review and approval by an FDA-approved Radioactive Drug Research Committee (RDRC); and
2. Review and approval by an IRB that satisfies the requirements of 21 CFR part 56.

The two committees have separate responsibilities. The RDRC evaluates issues related to radioactive drug and radiation exposure, while the IRB evaluates the protection of human research participants. Neither committee replaces the other. The regulation also establishes reporting relationships, including requirements concerning adverse reactions and communications with FDA.

NIH and FDA could consider a comparable IRB and IBC review structure for clinical research involving biohazards. In this framework, IRB and IBC review functions would remain separate and distinct, and would not require either committee to make determinations outside its area of expertise. The framework would ensure that:

- Each committee can determine when review by the other is required;
- Both committees receive the information necessary to conduct their respective reviews;
- Approval status is documented and available to the other committee; and
- Relevant decisions, protocol changes, incidents, and safety information are communicated in a timely manner.

Should NIH consider such an approach, we recommend that this be included in any future final policy. The policy would also clarify the respective areas of responsibility. For a clinical study, IBC review would focus on biosafety matters such as containment, product administration, shedding, replication, integration, potential environmental release, occupational exposure, and response to accidental

exposure. The IRB would remain responsible for evaluating the rights, safety, and welfare of human research participants under 21 CFR part 56.

This approach would preserve the distinct expertise and authority of IRBs and IBCs while ensuring that the two oversight systems are connected when a clinical investigation under 21 CFR 312 presents biosafety concerns.

5. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Observation 9. Statements specific to clinical research are distributed throughout the draft policy, rather than organized as a single discussion specific to clinical research. Without a dedicated section specific to clinical research, we are concerned research professionals may miss certain nuances or requirements for this type of research.

Suggestion 9. We suggest NIH create a dedicated section in the draft policy that specifically discusses clinical research considerations, including those identified in Suggestions 1-8 above. Organizing clinical research-specific considerations together, in one place, will aid investigators and research teams in better understanding and satisfying their biosafety obligations when conducting biohazards research with human participants. If NIH chooses to include a dedicated section on clinical research, we suggest this section would supersede the suggested clinical research placement locations described above. This clinical research section might appear as a sub-section under Section IV and could include the following proposed language:

> ***[NEW] Section IV-4. Clinical Research Involving Administration of Biohazards Including Materials Capable of Genetic Modification to One or More Human Research Subjects***
>
> ***IBC review is required for the deliberate administration of products covered under the scope of this policy to one or more human research participants. This includes products containing nucleic acid molecules that have either undergone genetic modification (e.g., viral vectors, gene modified cellular therapies, novel agents or organisms, RNA-based technologies, etc.) or are capable of introducing genetic modifications (e.g., stable gene integration, gene editing, epigenetic changes, etc.) into human research participants, as outlined in the policy's definitions.***
>
> ***For initial submissions of research within the scope of the policy, and not otherwise specified in other sections, review and approval must be obtained from the IBC before initiation. This would include:***
>
> *[continued on next page]*

[continued from previous page]

- ***Higher risk clinical research involving deliberate administration to one or more human research participants of the following biohazards:***
  - ***Products that are capable of shedding, replicating, gene editing, or integrating.***
  - ***Products that require higher risk manipulations (e.g., aerosolization, bladder infusions).***
  - ***RG2 or higher wild type biological agents (e.g., challenge experiments for medical countermeasures).***

Clinical research cannot be initiated until IBC, and all other applicable institutional and regulatory authorization(s) and approvals have been obtained.

Clinical research involving lower risk agents and manipulations may be reviewed as outlined in Section IV-3. Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members. Clinical research falling into this category includes agents that have undergone genetic modification rendering them unlikely to cause human disease and that are not capable of shedding, replicating, gene editing, or genomic integration.

Exempt from this policy is research involving the delivery to one or more human research participants of nucleic acid molecules that contain under 100 nucleotides in length and:

- ***Are not capable of: creating durable genetic modification, including genomic integration or gene editing, and***
- ***Do not encode functional portions of toxins, oncogenes, prions, or self-aggregating products capable of causing neurodegenerative disease in human or animals.***

The exemption does not apply to use of viral vectors, gene modified microorganisms, or other agents covered by this policy. Delivery of guide RNA for gene editing requires IBC review and is not covered under this exemption.

When the level of IBC review is not clearly outlined in this policy, refer to Section V-D. "Requirements and Considerations for Risk Assessment of Manipulations of Biohazards."

Clinical research involving handling and administration of potentially biohazardous materials to research participants is most often conducted in clinical settings that do not conform to laboratory BSLs. However, precautions to protect personnel must include the use of standard precautions such as gloves, and eye and respiratory protection.

Observation 10. We note the draft policy expressly requires IBC review and approval before initiation of clinical research involving deliberate administration to human research participants of products capable of shedding, replicating, or integrating; products requiring higher-risk manipulations, including aerosolization or bladder infusion; or Risk Group 2 or higher wild type biological agents.

As discussed in Observation 8 above, the draft policy does not establish a comprehensive reference to gene therapy clinical research as a distinct category for purposes of biosafety oversight and review. Nor does the draft policy consider that many viral vectors, gene-edited products, genetically modified cellular therapies, and certain other gene therapy products may shed, replicate, integrate, or require higher-risk administration, which in our opinion would fall under the types of clinical research involving deliberate administration to human research participants as listed in the draft policy.

Suggestion 10. We recommend NIH clarify how the draft policy applies to clinical research involving gene therapy products, genetically modified cellular products, genome-editing products, viral and nonviral vectors, genetic vaccines, and RNA-based technologies. Although Section IV-2 identifies clinical research involving products capable of shedding, replicating, or integrating, the draft policy does not define these terms or provide a product-specific framework for determining when IBC review is required.

NIH could provide definitions, examples, and a decision framework addressing at least the following:

- In vivo and ex vivo gene-therapy products;
- Viral vectors, replicons, and nonviral delivery systems;
- Genome editing products and whether editing constitutes integration;
- Proliferation of administered cells and whether it constitutes replication;
- Transient detection, persistence, and shedding;
- Products with replication-defective or replication-competent components; and
- The appropriate endpoint for IBC oversight when biosafety risks may continue after administration of the final dose.

Observation 11. In the second sentence of the penultimate paragraph of Section V-E, the draft policy uses the phrase "universal precautions," which we understand to be an outdated term that the U.S. Centers for Disease Control and Prevention (CDC) replaced with the term "standard precautions" in 1996.[8]

Suggestion 11. We recommend NIH revise Section V-E to replace "universal" with "standard" in the second sentence of the penultimate paragraph in this section:

[REVISED] However, precautions to protect personnel must include the use of ***standard*** precautions such as gloves, and eye and respiratory protection.

Observation 12. Section III-A "Responsibilities of the Institution" in the draft policy proposes the requirement for an Authorized Organization Representative (AOR) to provide written assurance every four years that the institution will comply with the policy.

Suggestion 12. When an institution uses an externally operated IBC, it will need guidance on how to provide assurance for the administrative responsibilities of the externally operated IBC to maintain the IBC roster, chair name, and meeting minutes on behalf of the institution. We recommend achieving this through a reliance agreement or some form of memorandum of understanding between the external IBC and the AOR at the institution.

In closing, Advarra is grateful for the opportunity to provide NIH with our comments on the draft NIH Biosafety Policy for Research Involving Biohazards. Please feel free to contact us as we would be happy to participate in further discussion on this matter. Should NIH create any working groups or stakeholder meetings to address the comments and/or draft guidance, we are fully willing to attend and assist in this endeavor.

Sincerely,

Lauri Carlile
Chief Research Services Officer

I am responding: On behalf of myself

Name: Elyse Walk

Name of Organization:

Type of Organization: Non-Profit Research Organization

Role: Other

Role - Other: Biosafety Associate Director

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical research and education

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I appreciate the opportunity to comment. I support the goal of modernizing biosafety oversight and offer the following concerns about scope and definitions to improve clarity, consistency, and workability.

Toxin scope and oversight do not align. Section II covers "toxins" with no threshold, while the definition is limited to proteins or peptides that harm humans. IV-2 assigns full review to Select Agent toxins, yet the Select Agent list includes toxins that do not appear to be proteins or peptides, such as tetrodotoxin and saxitoxin. The policy should clarify whether these are covered by the Select Agent reference, the definition, or both. IV-3 allows delegated review for "biological toxin proteins not on the Select Agent list." Section V-A recognizes that risk depends on potency, amount, and form (such as isolated subunits), but none of these factors appear in the scope or review categories. It is also unclear whether inactive derivatives, toxin-encoding nucleic acids, or low-potency proteins are covered, and why peptides are defined as toxins but IV-3 mentions only proteins. Without a de minimis or potency threshold, the literal language creates significant administrative burden.

Animal hazards are treated inconsistently. Section II covers wild-type agents only if they cause disease in humans, which appears to exclude animal-only pathogens. Yet the policy covers prions that cause disease in animals, defines zoonotic agents, requires animal-containment expertise on some IBCs, requires IBC review of incidents involving research animals, and addresses ABSL containment. The threshold definition should be reconciled with these provisions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Sections IV-2 and IV-3 overlap. IV-2 assigns full IBC review to "genetically modified cells, viruses, or organisms, other than plants," without limiting this by risk group. IV-3 allows delegated review for genetically modified RG1 agents, transgenic organisms at BSL-1/ABSL-1, certain plasmids and viral vectors, and well-characterized cell lines. IV-2's introductory language ("not otherwise specified in other sections") may be meant to resolve this, but IV-2 names genetically modified organisms itself. The final policy should state explicitly

which provision controls.

Occupational health. Section III-A says an institution "may be required" to maintain an occupational health and safety program under other regulations, or if "needed based on research conducted," while Section III-C makes the PI responsible for explaining procedures "advised or required." The policy does not say what triggers the need, who decides, or who develops the procedures. Section V-E shows the policy can state a trigger when intended: it requires an occupational health plan for certain influenza work. IBC membership requirements also do not include occupational health expertise.

IBC composition and capacity. The animal-containment expertise requirement applies only to animals too large for primary containment isolators. Routine small-animal work at ABSL-1 to ABSL-3, which the policy also covers, triggers no expertise requirement. The draft also adds substantial IBC duties, including expanded protocol and incident review, review of lower-risk incidents, public posting of minutes and incident reports, record maintenance, and coordination of NIH approval requests. It does not give IBCs explicit authority to suspend unsafe research, accreditation or certification standards, protections for institutional independence, specific national training resources, or funding. Responsibilities should be matched with authority and resources.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reporting and public posting. Section III-B requires public posting of all incident reports after "appropriate and allowable redactions," but the Policy does not define these. The draft template does, and its standard is narrow: it requires the PI's name and prohibits redacting information available from public sources. Because the posting requirement extends to lower-risk incidents that are not reportable to NIH, this may discourage reporting, and individuals may be identifiable from position titles and timelines in small laboratories. Redaction standards should be defined in the Policy itself, with careful consideration of whether lower-risk incidents require PI identification.

IBC meeting minutes template. Section III-B requires IBCs to use the draft minutes template and to post approved minutes publicly. The template calls for a detailed narrative for each protocol (agent characteristics, sources of nucleic acid sequences, vectors, modifications, manipulations, risk assessment, protocol-specific training, occupational health review, containment level, and vote), as well as incident reviews, inspection results, IBC training, attendees, and other business, and it states that discussion of any research subject to the Policy should be captured. The draft also expands scope to all biohazards, including toxins, genetically modified cells and organisms, and primary cells, and adds IBC review of lower-risk incidents. The volume of material in each set of minutes will therefore rise substantially, particularly for committees that review many low-risk protocols. I recommend that NIH (1) specify a minimum set of required elements and let institutions set the level of detail based on risk; (2) allow concise or batched summaries of routine, low-risk protocols and delegated approvals, with full records retained for audit and available to NIH; and (3) reconcile Section IV-3, which says delegated approvals must be reported "in full" to the IBC, with the template, which says they may be attached as a list.

6. Other feedback relevant to this resource: I largely agree with much of what CSHEMA as provided in terms of implementation:
Timeline and research continuity. Section II sets the effective date six months after publication of the final Policy, and Section III-A prohibits any covered research until NIH has approved an institutional Biosafety Assurance. The draft also says NIH intends to provide implementation resources, which means they may not exist when the clock starts. In six months, institutions would need to inventory newly covered research, prepare and obtain approval of assurances, revise procedures and electronic systems, build public-posting and redaction processes, train staff, and in some cases establish new IBCs. I recommend (1) a longer phased implementation period (for example, 24 months) that begins only after the final Policy and implementation materials are released; (2) a transition mechanism, such as provisional or deemed assurances and continued validity of existing IBC approvals, so that ongoing research is not interrupted while NIH reviews assurances; and (3) piloting of the assurance, minutes, and incident-reporting templates at institutions of different sizes and resources before they become mandatory.

Implementation resources. The most useful materials would be a Biosafety Assurance template, model procedures, decision tables with worked examples for each oversight category, sample completed minutes and incident reports, clear redaction guidance, and guidance for shared or externally administered IBCs.

Training. Training is required for IBC members, BSOs, PIs, and laboratory staff, but no minimum standard or responsible training authority is established. NIH's implementation resources should address this.

Cost. The draft adds substantial new obligations without addressing funding. NIH should consider how institutions, particularly smaller ones, will cover the cost of compliance.

Thank you for considering these comments.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Re: Request for Comment — Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)
To the Office of Science Policy:

Thank you for the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. I am a genetic engineer with 25 years of experience in the field, working in a mouse model core facility at a research institute. I am submitting these comments solely as an individual; the views expressed are my own and do not represent the position of my institution or employer.

At the outset, I want to commend NIH for undertaking this effort. The foundational Guidelines have served the research enterprise well, but a framework established roughly half a century ago was due for a thorough refresh. It is worth recalling that the original recombinant DNA requirements arose in the 1970s, long before the advent of PCR or the development of gene targeting in the mouse genome. They were written for a scientific landscape that no longer describes much of today's work. In that era, viral means of transgenesis posed a genuine health concern for laboratory staff, a concern that is simply not present in the non-viral gene editing performed today. Modernizing biosafety oversight so that it keeps pace with how science is actually conducted, and with the actual risks it presents, is both overdue and welcome, and I appreciate the care and extensive community engagement that have gone into this proposal.

My comments are narrow and concern a single category of research: the generation of genetically modified mouse models by non-viral methods. By this I mean techniques such as single-cell CRISPR injection into embryos and the editing of mouse embryonic stem cell lines to derive novel mouse lines from edited stem cells. I want to be clear about what I am not addressing. I am not arguing against IBC oversight of in vivo viral work, which involves vectors capable of replication or transmission and presents

genuine biosafety considerations that an IBC is well suited to review. My comments are confined to non-viral germline modification of mice, where no infectious agent and no replication-competent vector is involved, and where the only product of the work is a novel mouse.

Existing expert oversight already covers this work comprehensively. The draft policy would bring non-viral generation of genetically modified mouse lines within IBC review (as delegable review under Section IV-3). At my institution, this activity is already subject to a layered structure of oversight by subject-matter experts. A dedicated committee reviews the generation of all new genetically modified mouse models. The Institutional Animal Care and Use Committee oversees all maintenance and crossbreeding of those models. And the IBC already works closely with the IACUC to oversee all in vivo viral use. Adding a further IBC review for the non-viral generation of mouse models would duplicate oversight that competent, specialized bodies already provide, creating administrative burden without a corresponding gain in safety. This runs counter to the draft's own stated aim of removing red tape for low-risk research and streamlining administrative burden.

IBCs should remain focused on their core mission. An IBC's central purpose is to protect human safety and to weigh societal and environmental impact. That mission is best served when the committee's finite attention is directed to the activities that actually implicate it. Non-viral generation of genetically modified mouse models does not. The techniques at issue carry such a low probability of any adverse event that routine IBC review of them does not advance human safety; it diverts committee time and expertise away from the higher-risk work where that scrutiny matters most. Layering oversight onto this category risks diluting, rather than strengthening, the IBC's effectiveness.

The uncertainty inherent in novel models does not justify added oversight, because the ceiling on plausible harm is so low. I want to address directly what might seem like a counterargument. It is true that generating a novel mouse model often produces an animal whose exact phenotype cannot be fully predicted in advance; knocking out a gene can yield genuinely novel biology, and the precise consequences are frequently unknown until the animal is characterized. Asking an IBC to anticipate those consequences in advance is, in a real sense, a Sisyphean task. But the relevant question for biosafety oversight is not whether an outcome is uncertain; it is whether a plausible worst-case outcome poses meaningful risk. For a non-virally generated genetically modified mouse, even the worst-case scenario presents a negligible hazard to laboratory staff, to other mice, or to society at large. A mouse carrying an edited genome is not infectious, is not transmissible to humans, and is maintained under existing animal-care controls. Where the upper bound on harm is this low, additional layers of oversight would slow the pace of science without producing any measurable improvement in either safety or the quality of the research.

The scale of this activity, and the draft's treatment of crossbreeding, illustrate the burden concretely. At my institution alone, we maintain nearly 1,000 different combinations of genetically modified mouse lines across varying genetic backgrounds. In a typical year, roughly 150 new mouse crosses are generated and about 150 are retired. This work is overseen by the IACUC, which is appropriate, because it largely represents the crossbreeding of existing, already-characterized mouse lines; this is an animal-husbandry activity rather than the introduction of any new genetic material or agent. As drafted, however, the policy's scope implies that the crossbreeding of genetically modified mice would fall to the IBC. Routing

an activity of this volume and this low risk through IBC review would impose a substantial and recurring administrative load with no attendant safety benefit, and it illustrates precisely why institutions need flexibility in how this category of work is overseen.

Recommendation. I respectfully recommend that the final policy afford institutions the flexibility to assign oversight of the non-viral generation of genetically modified mouse models to an appropriate institutional body other than the IBC, rather than requiring IBC review in every case. The aim is not to remove this work from oversight, but to allow it to be reviewed by the body best suited to the task. At my own institution, for example, a dedicated committee already reviews the generation of all new genetically modified mouse lines and has the specialized expertise to do so effectively. Permitting an institution to designate such a committee, in coordination with its IACUC and with the IBC retaining jurisdiction over any work involving replication-competent or transmissible agents, would preserve rigorous, expert oversight while avoiding duplicative review and keeping the IBC's attention on the higher-risk work it is uniquely positioned to assess. This approach would be fully consistent with the tiered, risk-calibrated structure the draft seeks to establish and with its recognition of institutional oversight as a foundational pillar.

Thank you for considering these comments and for your continued work to modernize biosafety oversight in a way that is both rigorous and proportionate.

RE: Comments on Draft NIH Biosafety Policy for Research Involving Biohazards, NOT-OD-26-112

Submitted electronically to the NIH Office of Science Policy

Dear Director Bhattacharya:

The Association for Research in Vision and Ophthalmology (ARVO) appreciates the opportunity to comment on the National Institutes of Health (NIH) Draft Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112). ARVO is an international scientific society of vision and ophthalmology researchers whose members investigate biological mechanisms, develop and validate research models, and translate discoveries into approaches to prevent vision loss and improve eye health.

ARVO supports strong biosafety protections, responsible institutional oversight, transparency, and NIH's objective of modernizing a framework developed around recombinant and synthetic nucleic acid research. We also welcome the proposal's stated commitment to reducing unnecessary oversight for lower-risk work. However, we believe the final policy must define covered activities and risk thresholds with sufficient precision so routine research does not face burdens disproportionate to the actual biological hazards it may present.

Vision research draws upon animal and human-derived models, including genetically modified mice and zebrafish, human donor ocular tissues, primary retinal and anterior segment cells (e.g., lens, trabecular meshwork and cornea), stem-cell retinal organoids, and gene delivery platforms. These methods are not interchangeable, and relevant biosafety risks depend on the material, experimental manipulation, route of exposure, containment, and documented source characteristics, not simply on the type of model used.

Scope and Risk-Proportionate Review (Sections II and IV)

The proposed policy influences biohazard research conducted at institutions that receive NIH support even when individual projects are supported by other sponsors. NIH should clarify how this institutional reach applies to privately supported studies, collaborations, shared facilities, and storerooms, and state authorities when applicable. The policy should identify how institutions may rely on other appropriate federal oversight, and explain which activities qualify for delegated rather than full IBC review. NIH should provide practical examples for common vision-science methods (and other methods as appropriate), including low-risk genetically modified animals, human-derived cells, and nonreplicating gene delivery systems. A genetic modification or variant should not alone be treated as a proxy for a significant human-health hazard.

Primary Cells and Adventitious Agents (Section IV-2)

We are particularly concerned by the proposal to require IBC review of "primary cells that may be contaminated by adventitious agents." Without definitions or an articulated risk threshold, this phrase could be interpreted to capture a broad array of primary human and animal cells and tissues where the absence of every possible agent has not been conclusively demonstrated. Such an interpretation could include donor-derived retinal tissue, retinal pigment epithelial and corneal cells, patient-derived ocular materials, and nonhuman primate cells or tissues used in vision research. Some sources and specimens warrant significant precautions, but a merely theoretical possibility of contamination is not a sound basis for

uniform full-committee review. Additionally, the eye banks that provide donor eyes are already under strict regulation by federal agencies for infectious agents due to corneal transplants.

NIH should clearly define “adventitious agent,” distinguish known or reasonably anticipated hazards from hypothetical possibilities, and clarify how donor screening, testing, specimen provenance, supplier documentation, handling conditions, and exposure pathways inform risk assessment. Guidance should also specifically address commercial primary cells, storeroom materials, patient-derived specimens, and primary animal tissues, including nonhuman primate materials, for which risks may differ significantly by species and source. NIH should provide examples of included and excluded materials, explicitly permit documented institutional assessment or delegated review when risk is low, and require screening and source documentation to inform a comprehensive biosafety assessment.

This clarity is especially important given NIH’s priority of human-based research methods and the shift to New Approach Methodologies (NAMs). Ambiguous treatment of primary cells could slow adoption of organoids, tissue-based disease models, and other NAMs without a demonstrated, materially significant safety benefit.

Animal Models and Complementary Institutional Oversight

Genetically modified mice and zebrafish are also essential tools for understanding retinal development, inherited and age-related retinal degenerations, glaucoma, dry eye disease, optic nerve injury, and visual recovery. Where hazards are well characterized and containment is appropriate, institutions should follow streamlined, risk-based pathways. Shared documentation, coordinated review, and clear responsibility for biosafety versus animal-welfare determinations can preserve safeguards while avoiding ongoing reviews that delay research. The final policy should also distinguish routine husbandry incidents from events presenting a meaningful biosafety concern.

Human-Derived Models, Gene Delivery, and Translation

Investigators use human retinal organoids, induced pluripotent stem-cell-derived systems, gene-edited cell models, and viral or nonviral delivery tools to study disease and develop potential therapies. The oversight process should reflect whether a material is infectious or can replicate, whether manipulation materially changes risk, and what exposure is plausible. NIH should publish examples for commonly used appropriately characterized paths and cell systems to enable delegated review for activities with minimal risk. Consistent expectations across institutions and any approved international collaboration are especially important for collaborative, multisite studies and emerging researchers.

Transparency, Incident Reporting, and Research Security (Section III)

ARVO supports meaningful transparency, but public posting of IBC minutes and incident reports requires practical safeguards for personnel privacy, unpublished work, proprietary methods, facility security, and sensitive information. NIH should specify standardized redaction criteria and permit summaries when detailed disclosures do not advance public understanding. Incident thresholds should distinguish significant biosafety risks from minor, contained events addressed through local processes. Reporting should encourage prompt disclosure and institutional learning, not discourage internal reporting or invite misleading interpretations of routine laboratory events.

Implementation, Compliance, and Continuity (Sections II–V)

The proposed six-month implementation period is insufficient for institutions to revise policies, expand IBC capacity, train personnel, and align oversight across funding sources, especially with the other concerns outlined above still needing to be addressed. NIH should consider realistic administrative burden, operational cost, and implementation estimates and provide model procedures, templates, examples, training, and a phased implementation path that gives institutions more time to implement the proposal safely and effectively. Enforcement of the policy should be calibrated to actual risk profiles of the research pathways, impact severity, and remediation. Isolated and minor procedural issues should not automatically threaten unrelated NIH-supported vision research and the students, personnel, and patients who depend on its continuity.

Recommendations

1. Define “adventitious agent” and establish clear, reasonably anticipated human-health risk thresholds for primary cells, with examples across human and animal sources.
2. Provide explicit delegated or streamlined review pathways for appropriately characterized low-risk primary tissues, cell models, genetically modified animals, and delivery systems.
3. Clarify policy reach across funding sources and institutional collaborations and recognize appropriate existing federal, state, and institutional oversight.
4. Coordinate IBC review with other requirements without duplicative documentation or ongoing approvals where responsibilities are distinct, and risks are well characterized.
5. Set consistent disclosure, redaction, and incident-reporting standards that support accountability without compromising research security or mischaracterizing minor or routine events.
6. Publish practical implementation tools and allow a phased, longer transition informed by realistic institutional staffing, costs, and readiness, while addressing the concerns above.
7. Use risk-proportionate enforcement and corrective-action opportunities, protecting unrelated ongoing NIH awards from disproportionate disruption.
8. Additional clarity and guidance are also needed on whether this policy will apply retroactively to existing cells collected before policy implementation that have been safely used in research, and on any unique requirements for those existing collections, understanding the additional burden and threat the policy may have on existing research with those collections.

Conclusion

ARVO supports an effective and modern biosafety policy that protects research personnel and the public while sustaining important science. We encourage NIH to revise the draft to ensure that oversight requirements are clearly defined, proportional to reasonably anticipated risks, and workable across animal- and human-based systems that advance vision research. We welcome continued engagement with NIH leaders as NIH continues to develop the final policy and necessary accompanying guidance.

Thank you for the opportunity to provide comments.

Sincerely,

[redacted]

Iris M. Rush, CAE
Executive Director
Association for Research in Vision and Ophthalmology (ARVO)

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The significant concerns in these comments and raised by the broader scientific community demonstrate that the draft Policy cannot be implemented in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.
a. The stated intention of this policy proposal is to expand the scope of the NIH Guidelines while removing red tape for low-risk research. The goal of removing red tape for low-risk research within this Policy has not succeeded. The Draft Policy includes within its scope multiple categories of research that are currently Exempt in the NIH Guidelines. For example, research with certain transgenic rodents and certain recombinant work with non-pathogenic E. coli; the NIH Director has already determined that these experiments are of such low risk that they were actively designated as Exempt, yet this Policy considers them of high enough risk to require IBC approval. The Policy does not provide reasoning for this change in the risk assessment.
b. A meaningful administrative burden with the NIH Guidelines is the pathway through which NIH OSP will assign a biocontainment level for research with an agent that does not have an assigned RG within Appendix B. This issue could be less burdensome if NIH OSP had been granted authority within the Guidelines to assign a risk group to agents that do not have risk groups.
i. The current approval pathway is limited to the specific PI at a specific entity. Therefore, other PIs at the same entity are similarly required to obtain a biocontainment level from NIH OSP for the same agent.
ii. We recommend that the Policy clearly state that determinations of risk group and/or recommended biosafety levels will apply to all researchers and all entities subject to the Policy.

1. We understand that there will be differences in the recommended biosafety level due to geography/climate and considerations for research being performed outside the US, which should be considered if this recommended change is made to the Policy.
c. The Scope of the Policy states “Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained.”
i. This statement must be clarified. We appreciate that the Policy seeks to avoid duplicative oversight from multiple federal agencies. However, the statement itself is unclear regarding the oversight, approvals, and clearances that are mentioned.
1. If a researcher is registered to work with wildtype Nipah virus (RG4, therefore falling under Section IV-2) with the Federal Select Agent Program (FSAP), do they not need to obtain IBC approval for the same work?
2. If a researcher is registered to generate chimeras of paramyxoviruses within a Nipah virus backbone (a novel agent by the current definition, therefore falling under Section IV-1) with FSAP, do they need to obtain NIH and IBC approval for the same work?
3. If an incident occurs in a BSL3 or BSL4 that involves a Select Agent for which the researcher is registered with FSAP, does the incident get reported to NIH and posted on a public facing website?
d. Effective Date
i. The Policy states that the effective date will be 6 months from publication of the final Policy. This is a very short timeline to implement a Policy with such significant expansions in scope. Implementation of this Policy will require that IBCs ask for more resources from their institutions, obtain those resources, communicate with stakeholders, develop new training, implement training for IBC members and researchers, obtain new software or update software, and make significant choices in how to implement each part of the Policy. Six months is not nearly sufficient, and all entities will struggle.
ii. This is further complicated by the need to provide a written Biosafety Assurance that has been approved by NIH in order to perform any research after the effective date. Will NIH have the required full-time employees (FTEs) to review and approve hundreds of Biosafety Assurances that will be submitted within that effective date?
iii. We recommend that the effective date be at least 2 years.
e. The Policy uses terms and words but does not define them. The failure to define these words will lead to ambiguity in the interpretation and implementation of the Policy, leading to unintentional noncompliance. Further, some of these words did not have definitions in the NIH Guidelines and therefore this is a good opportunity to rectify this issue. These include:
i. Adventitious agent, organism, transgenic, GDMO, incident, release, potential risk to human health, peptide, shedding
1. Organism is inconsistently used within the Policy and is not an easily defined word. Replace “organism” with more appropriate and easily definable terms throughout the Policy. Specify bacteria, fungi, archaea, protists, viruses, or animals as needed. If there is a concern about a biological agent that doesn’t fall within those terms, be clear about that (e.g., a biological agent created through synthetic biology that cannot be readily categorized).
f. The Policy omits a review workflow for biological agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL yet cannot reasonably fall within the definition of “emerging, novel, or zoonotic agents”. This is a crippling issue for agents that are currently handled at BSL1 or BSL2, though is also an issue for agents handled at BSL3 and BSL4.

i. Theoretically, these could fall within Section IV-1 (research that requires NIH and IBC approval before initiation). However, the administrative burden on NIH to adequately review this work in a timely manner would be significant (even ignoring the administrative burden on researchers and IBCs to review this work). Additionally, much of this research cannot reasonably fall under the category of "higher risk research", when even research involving RG3 or RG4 wild-type biological agents requires only IBC review in the Policy.
ii. For example, human metapneumovirus, non-polio enteroviruses, human parainfluenza virus 5 (Orthorubulavirus mammalis), and Sendai virus (Respirovirus muris) are not emerging, novel, or zoonotic agents. Yet they lack a risk group in the NIH Guidelines and are not mentioned in the BMBL. Will NIH review be required for research with these agents for every entity and researcher that falls in scope of the Policy? If so, how many FTEs will NIH be hiring to accomplish timely reviews?
iii. How will human or animal microbiota be treated in this review workflow? Will research with every member of Bacteroides, Bifidobacterium, Akkermansia, Ruminococcus, Prevotella, and Anaerococcus require NIH review? If so, will a researcher even be able to collect a human or animal sample without being in noncompliance with the Policy?
g. The Policy does not define who has the authority to designate the risk group of an agent.
i. This is of particular importance with RG1 biological agents, since the Policy explicitly states that wild-type RG1 biological agents are outside the scope of the Policy.
ii. If the local IBC will have the authority to designate the risk group of an agent, that needs to be stated in the Policy.
iii. If the NIH will have the authority to designate the risk group of an agent, that needs to be stated in the Policy. In addition, NIH must publish and regularly update the list of biological agents that it designates at different RGs.
h. Responsibilities of the Institution (Section III-A), related to records retention
i. The Policy states "The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states "the recipient and subrecipient must retain all Federal award records for three years from the date of submission of their final financial report." (emphasis added).
ii. The Policy assumes that all IBC records are for projects that are federally funded. The Policy has failed to consider projects that are not federally funded and therefore will never submit a final financial report. As written, such IBC records may never be disposed of, which is either an oversight or regulatory overreach. This language must be changed to account for IBC records related to non-federally funded projects.
i. Responsibilities of the IBC (Section III-B), related to approval period
i. The Policy states "Approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required."
1. The Policy fails to describe how biosafety or biosecurity is increased by limiting research approvals to three years. Researchers continue projects over years and decades, and these projects rarely include changes that significantly increase the risk assessment.
2. Requiring a specific time frame for approvals is overly burdensome and regulatory overreach. Requiring such a short approval time will greatly increase the administrative burden of the IBC and the researcher for little to no increase in biosafety.
3. We recommend that this statement be removed from the Policy.

4. If the statement cannot be removed from the Policy, we recommend that the Policy explicitly permit grandfathering of previously approved IBC protocols that have approval periods of greater than three years.
j. Responsibilities of the IBC (Section III-B), incident reporting
i. The Policy does not define "incident" or "release". We recommend the following definitions:
1. Incident: A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.
2. Release (Loss of containment or occupational exposure): Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
ii. The Policy does not define "improper disposition" and throughout this section relies on ambiguous phrases such as "any incident", "loss of containment", "significant problems", and "minor spills … generally do not need to be reported". Terms like "first aid" and "medical treatment" should be aligned explicitly with OSHA standards.
k. Responsibilities of the NIH (Section III-D)
i. The Policy does not state which person or office within NIH will be responsible for these items. In comparison, the NIH Guidelines clearly delineated the responsibilities of the NIH Director and the responsibilities of the NIH Office of Science Policy.
1. Entities can reasonably expect that the response times for the NIH Director and for NIH OSP will be significantly different. Further, NIH OSP is staffed with many subject matter experts, while the NIH Director can never be an SME for every aspect of biomedical science. Therefore, the Policy must clearly state who will be responsible for these duties.
2. We recommend that the Policy clearly state which person or office is responsible for the duties described in this section.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): 2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).
a. In general, the tiered oversight is appreciated. The IACUC-style review that specifically permits delegate approval will be a helpful decrease to time commitments from the full IBC for review of lower risk research.
i. The Policy has replaced two previous categories of review, those requiring NIH Director approval (III-A) and those requiring NIH OSP approval (III-B), with a singular category that requires NIH approval. The Policy does not describe which person or office within NIH will be performing the review and approval of research within Section IV-1. This must be clearly stated in the Policy within the Responsibilities of NIH (III-D).
b. General Definitions: Emerging agent or organism
i. The Policy does not state who determines that an agent is an emerging agent. Does the local IBC decide what qualifies as an emerging agent? If not the local IBC, we recommend that NIH develop rapid dissemination notices that are sent to all entities identify emerging agents so that entities can avoid noncompliance.
ii. The Policy does not describe how an agent or organism goes from being an emerging agent to a non-emerging agent. Will an agent be "emerging" until the first time NIH has reviewed it under Section IV-1? Until it has been assigned a risk group? Until it has appeared in the next edition of the BMBL?
iii. Does the definition of an emerging agent include a well characterized agent that exhibits a change in pathogenicity or transmission? If this Policy existed at the time, would the recent outbreaks of Zika virus,

mpox virus, and Andes virus qualify as “emerging”? Would the label of emerging apply to the agent, or merely to the specific strain of the biological agent?
iv. If considered now (October 2026), which agents would qualify as “emerging”? Highly pathogenic avian influenza virus H5N1? SARS-CoV-2?
c. General Definitions: Genetic Modification
i. This definition is so expansive that it causes internal contradictions within the Policy.
ii. The definition uses the undefined word “organisms”, which is unhelpful. As written, this causes the Policy to confusingly regulate research conducted with genetically modified organisms (Section IV-2) differently from transgenic organisms (Section IV-3) but does not define the difference between the two. We recommend replacing the word organism with the biological agent(s) that are intended to be within scope of the Policy.
iii. Can be transcribed or translated: as written, this will include expression from an RNA vaccine that is administered to an animal or transfected into a cell line. The Policy does not describe how including this as a genetic modification addresses a biosafety concern.
iv. The introduction … of stable alterations into the genome by passaging, reassortment, chemical or radiological means: as written, the definition includes unintentional alterations into the genome, such that researchers will become noncompliant with the Policy almost immediately.
1. Passaging any virus in tissue culture will result in unintentional alterations into the genome.
2. Cancer research includes work with antineoplastic drugs that would fall within scope of this definition.
3. We recommend that this definition be re-written to be limited to intentional stable modifications.
d. General Definitions: Toxin
i. The definition of toxin could be greatly improved.
ii. For example, ISO35001 uses “substance, produced by plants, animals, protists, fungi, bacteria, or viruses, which in small or moderate amounts produces an adverse effect in humans, animals, or plants. This includes substances and materials, natural or as a result of biotechnology, that may contain toxins, any poisonous substance or any poisonous isomer, homologue, or derivative of such a substance.”
1. The definition should not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (e.g., sensitizers).
2. Later in the Policy, when defining the Category of research, would be the appropriate time to limit the scope of which toxins fall under the Policy (e.g., Research with protein or peptide toxins not on the Select Agent list and with an LD50 of less than 100 micrograms per kg body weight.)
e. Section IV-1 (Research that Requires NIH and IBC Approval Before Initiation): Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL.
i. Emerging and zoonotic agents:
1. For those whose research focuses on the identification of new biological agents, the Policy offers no regulatory path to work with these agents. Once identified as an emerging or zoonotic agent with no risk group or biosafety level recommended in the BMBL, the research must be approved by NIH. However, without the ability to work with the agent, the researcher cannot generate the data required for NIH to conduct the risk assessment.
2. Without the ability to perform this research, US researchers will stop performing this work. It will then fall to international researchers to spearhead this work, leaving US researchers lagging behind.
3. We recommend that a clear approval pathway is described in the Policy to allow researchers to generate the data required for a risk assessment. This would best be performed by the local IBC.

ii. Novel agents:
1. The definition of novel agents includes chimeras. Many researchers generate chimeras (especially within a family of viruses) to study the basic biology of these agents; in these cases, the representative family member or the parental agents often already have risk groups assigned or biosafety levels recommended. Research with such biological agents does not qualify as "higher risk research" requiring NIH approval; indeed, these experiments currently fall within Section III-D of the NIH Guidelines, clearly demonstrating that for decades NIH has determined that the work can be reviewed by the local IBC and does not require NIH approval.
2. Scientists tend to use the words "emerging" and "novel" interchangeably. The definition provided in the Policy for "novel" might more accurately be described as "bioengineered" by the regulated community.
3. We recommend that research involving chimeric agents generated within the same family (for viruses) or the same genus (for bacteria or fungi), may be reviewed by the IBC.
4. We recommend that research involving chimeric agents where the natural sources have risk groups assigned and/or biosafety levels recommended, may be reviewed by the IBC.
f. Section IV-2 (Research That Requires IBC Review and Approval Before Initiation)
i. This section states "For initial submissions of research within the scope of the policy, and not otherwise specified in other sections, review and approval must be obtained from the IBC before initiation."
ii. Since the Policy includes a regulatory catch-all ("not otherwise specified in other sections"), the Policy must include a section that clearly delineates research that is outside the scope of the Policy. Institutions cannot rely on one-off notes to define research that is outside the scope (e.g., "[Note: Experiments involving RG1 wild-type biological agents are not subject to this Policy]"). Without clear delineation, entities will vary widely between unintentional noncompliance and overly requiring IBC review and approval for work that is outside the scope of the policy.
g. Section IV-2: Research involving RG3 or RG4 wild-type biological agents.
i. We have no objection to including RG3 and RG4 biological agents within scope of the Policy, as our institution already requires that work with these agents be approved by the local IBC.
h. Section IV-2: Research involving genetically modified cells, viruses, or organisms, other than plants (e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs).
i. Policy must be well written and clear; this category is a clear example of policy that is not well written. It is misplaced within the tiers of review; contains terms that are either not defined or badly defined; and conflicts with other categories of research within the Policy. Entities will be uncertain how to comply with this category, leading to chilling effects on the research community, additional administrative burden, and unintentional failures to comply with the Policy.
ii. This category is misplaced within the tiers of review. Research with genetically modified cells should be at most within Section IV-3 (delegate review), if not Exempted completely.
1. The NIH Guidelines has included an exemption for recombinant DNA molecules containing less than one-half of any eukaryotic viral genome that are propagated and maintained in tissue culture at least since the Federal Register Notice in 1994 (Effective June 24, 1994, Published in Federal Register, July 5, 1994 (59 FR 34472)). The NIH Director has therefore determined that such experiments do not present a significant risk to health or the environment. The Policy does not describe how the inclusion of such research in the Policy will increase biosafety and biosecurity. In addition, while a single researcher registering for this work would not be a significant burden, the total number of registrations will constitute a significant collective administrative burden on the IBC and researchers that is not

commensurate with the very low biosafety risk.
2. Genetic modification of cells is of very low biosafety risk (barring some introduction of nucleic acids from certain biological agents, like RG3 or RG4 agents, or that will generate toxins). Such work should be exempt from the Policy.
iii. Genetic modification is defined by the Policy, but in such an expansive way that it is prohibitive to research.
1. As an example: as written, the Policy no longer considers administration of recombinant nucleic acids (e.g., RNA vaccines) in humans to be within scope, compared to the NIH Guidelines, where it is within scope (Section III-C-1). However, the Policy includes "genetic modification" of cells and organisms, which as defined includes introduction of nucleic acid molecules that can be transcribed or translated (e.g., RNA vaccines). The Policy does not describe how it has conducted a risk assessment in which deliberate administration of an RNA vaccine into a human is not within scope, yet transfection of the RNA vaccine into cell culture or administration into an animal is within scope and requires IBC approval.
iv. Organism is not defined by the Policy, which makes this category frustrating to understand and will lead to significant unintentional noncompliance.
1. As written, this category appears to include animals, despite the category of "transgenic organisms at BSL1/ABSL1" listed in Section IV-3.
2. The word organism must be defined by the policy or replaced in this section.
v. Vector is not defined by the Policy, which will lead to significant unintentional noncompliance. Is the intention here to regulate viral vectors (e.g., lentiviral), arthropod disease vectors (e.g., mosquitoes), or something else?
vi. Gene drive modified biological agents is not defined and is a confusing term. Biological agents in the Policy are defined as bacteria, viruses, fungi, or parasites, yet gene drive technology requires Mendelian genetics, such that this would be limited to fungi or parasites. The subsequent use of GDMO in this category suggests that gene drive modified biological agents are different from GDMOs, but this delineation is not clear.
vii. GDMOs are not defined in the Policy.
viii. We recommend that this category be removed from the Policy or extensively re-written, as described below.
1. The definition for Genetic Modification should be re-written to be limited to stable alterations in the genome. Definitions for organism, vector, GDMO and gene drive modified biological agents must be added to the Policy (or removed).
2. Research with genetically modified risk group 3 and 4 biological agents should be approved by the IBC. Research with genetically modified risk group 2 biological agents should be approved by IBC delegate.
3. Research with GMDOs should be approved by the IBC.
4. Review and approval of research with genetically modified cells should be dependent on the modification, some of which may fall within IBC approval, delegate approval, or be completely exempt from the Policy.
i. Section IV-2: Research with primary cells that may be contaminated by adventitious agents.
i. As noted above, the Policy does not define adventitious agents. Therefore, entities will be uncertain how to comply with this regulation and will rapidly be in noncompliance.
ii. If the intention of the Policy is to regulate primary cells that may be contaminated by bloodborne pathogens, there is a significant risk assessment issue: research with samples that may be contaminated requires full IBC review, yet research with known RG2 biological agents requires delegate review.

iii. For clinical samples suspected to contain higher consequence pathogens (Brucella, Herpes B, M. tuberculosis, etc.), the BMBL states that BSL2 practices, containment equipment, and facilities are recommended for routine handing of clinical specimens of human or animal origin. The Policy should harmonize the level of review required for these samples: at most they should require delegate review.
1. We recommend that this section be removed from the Policy.
2. If it must be regulated by the Policy, "adventitious agent" must be clearly defined within the Policy.
3. If it must be regulated by this Policy, we recommend that this work not require IBC or delegate approval as long as the entity is complying with OSHA Bloodborne Pathogens Standard or its equivalent.
4. If it must be regulated by this Policy, we recommend that it should not fall under the category of requiring IBC approval and should at most be in Section IV-3, where delegated review is permitted.
iv. If the intention of the Policy is to regulate primary cells that may be contaminated by any unknown biohazard (for example field samples), that is not clear and needs to be much more clearly defined.
j. Section IV-2: Research with wild type or genetically modified RG2 biological agents for which lower containment is requested, or research with wild type or genetically modified RG3 or RG4 biological agents that NIH has previously approved to be conducted at lower containment.
i. The Policy implies that there will be a workflow of (1) an entity submits an initial request for NIH to lower containment involving wild type or genetically modified RG3 or RG4 biological agents, (2) NIH will make a determination on whether that lower containment is appropriate, (3) NIH will be responsible for publishing approved determinations of appropriate lower containment for these agents, (4) subsequently, research involving these agents may be approved by the IBC alone (without NIH approval).
1. This workflow should be expressly stated in the Policy to minimize confusion. This includes a clear statement that once NIH has made the determination and published it, other entities will not be required to obtain NIH approval. This would be in contrast to the current system, where approvals are provided only to the single PI at the single institution.
2. The method by which NIH will publish these determinations should be described, including the minimum time frame (determinations will be published within 1 month, within 6 months, annually, etc.).
3. The Policy should be clear on how much information will be released together with these determinations. Specifically, whether the information includes security sensitive information or unpublished data.
k. Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): Research involving RG2 wild type biological agents.
i. We have no objection to including RG2 biological agents within scope of the Policy, as our institution already requires that work with these agents be approved by the local IBC.
ii. However, we are very concerned that there is not a thorough list of RG2 biological agents and/or biological agents that are recommended to be worked with at BSL2. Will all agents not listed in the BMBL require review by NIH?
iii. We recommend that the NIH make a detailed, publicly available list of RG1, RG2, RG3, and RG4 biological agents to supplement the BMBL. Appendix B of the NIH Guidelines should serve as the backbone of this document.
1. The inclusion of RG1 organisms is an important part of such a list, since they are outside the scope of the Policy, yet the Policy specifically states that "absence of agent specification in the list of RG2-RG4 does not imply automatic or implicit classification as RG1".
2. If other federal entities (USDA, CDC, etc.) participated in creating a central list that also includes plant or agricultural considerations, that would be greatly appreciated.

iv. If NIH cannot make a detailed publicly available list of RG1, RG2, RG3, and RG4 biological agents to supplement the BMBL, we recommend that the Policy clearly states that the local IBC has the authority to perform the risk assessment and make that determination.
l. Section IV-3: Research conducted with transgenic organisms at BSL-1/ABSL-1.
i. The purchase and transfer of transgenic rodents requiring BL1 containment is exempt in the NIH Guidelines (Appendix C-VII). Further, the generation of certain BL1 transgenic rodents is exempt in the NIH Guidelines (Appendix C-VIII). In 2011, NIH deemed that "… these breeding experiments do not pose an appreciable risk to human health or to the environment. In addition, while registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk." (January 19, 2011, Federal Register, January 19, 2011 (76 FR 3150)). As documented in NIH guidance documents, the subsequent use of these BL1 transgenic rodents is also exempt (https://osp.od.nih.gov/wp-content/uploads/2022/11/Animal_Activities_Table.pdf). The same risk assessment should apply today, and the Policy should not require that work with transgenic rodents that can be housed at ABSL1 be approved by the IBC.
ii. As noted previously, there is no definition of organism in the Policy. Therefore, we recommend changing this to animal in this section.
iii. We understand that research with some transgenic animals may not have had the time to demonstrate the same safety track record as transgenic rodents and therefore should continue to require IBC approval before that research is conducted. We would recommend that NIH seriously consider that transgenic fruit flies or zebrafish could be exempted due to their safety track record.
iv. We recommend that this be re-written as: Research conducted with transgenic animals, other than transgenic rodents, fruit flies, and zebrafish that may be housed at minimum BSL-1/ABSL-1/ACL-1.
m. Section IV-3: Research with genetically modified RG1 biological agents.
i. Certain research not requiring NIH-OSP approval and not involving DNA from RG3, RG4, or restricted organisms with specific risk group 1 biological agents is exempt in the NIH Guidelines (Appendices C-II, C-III, C-IV, and C-V), having been determined by the NIH Director to not present a significant risk to health or the environment. The Category here (research with genetically modified RG1 biological agents) icontradicts this determination and would require that work that was previously exempt now requires IBC approval. The Policy has not described why this risk assessment has changed.
ii. We recommend that this category be removed from the Policy.
iii. Additionally, a list of RG1 biological agents is not available. If any part of the Policy references RG1 biological agents, including as work that is outside the scope of the Policy, a list should be developed and published by NIH as part of this Policy, or the local IBC should be granted the authority to designate agents as RG1.
n. Section IV-3: Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes.
