i. This category of research is of low biosafety and biosecurity risk. The Policy fails to describe how regulating this research will increase biosafety or biosecurity. This category will set entities up for failure, with no clear benefits to our biosafety programs.
ii. Registering research with plasmids will lead to extensive unintentional noncompliance. Researchers generate plasmids regularly and the requirement to obtain approval for these plasmids from the IBC will be a severe bottleneck.
iii. The Policy fails to describe the extent of what is required to be registered as part of this section. Only

the plasmid backbone? The backbone with every gene the researcher will insert? The backbone with every gene and every mutation of that gene?
iv. The administrative burden for researchers and the IBC will be significant and is not balanced by any increase in biological safety.
v. We recommend that this category be removed from the Policy.
o. Section IV-3: Research with well-characterized cell lines.
i. Registering work with well characterized cell lines will lead to extensive unintentional noncompliance. The administrative burden will be crippling for researchers and IBCs. This category will set entities up for failure, with no clear benefits to our biosafety programs.
ii. The Policy fails to describe the biosafety concern that is being addressed by this category of research.
iii. The Policy does not describe the extent of what is required to be registered. Is it solely that a researcher is performing work with cell lines? Is it every cell line that the researcher will work with? May the entire ATCC catalogue be approved?
iv. We recommend that this category be removed from the Policy.
p. Section IV-3: Research with biological toxin proteins not on the Select Agent list.
i. Under the definition within the Policy, this category includes food allergens, animal allergens, even FBS, since they can cause harm to humans, yet there is no indication that this is intended. The milk that a researcher is using as part of a Western blot falls within the scope of this category.
1. There is a conflict between the wording in this Section (research with biological toxin proteins) and the definition in the Policy for Toxin (a protein or peptide produced …). This conflict makes it difficult to understand what is within the scope of the category.
ii. This category of research must include a clear definition of which toxins are within scope, including an LD50, or entities will be inadvertently noncompliant.
iii. At our institution, work with toxins are already regulated by our Chemical Safety Committee, which provides regulatory oversight of this work. Additional oversight by the IBC will not increase safety and will instead increase regulatory burden.
iv. We recommend that this category be removed from the Policy.
v. If this category is not removed, we recommend that this be re-written as: Research with biological toxin proteins with an LD50 in vertebrates of <100 micrograms per kilograms of body weight.
1. Additionally, a list of toxins currently classified under this category must be provided in the Policy. The list of toxin molecules classified as to LD50 that is currently available from NIH OSP under the NIH Guidelines (Appendix F-1) should serve as the backbone of this list.

3. Continued utility of Risk Groups: 3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).
a. Risk Groups as Hazard Characterizations vs. Site-Specific Risk Assessment
i. Risk Groups remain valuable tools for initial hazard communication and agent characterization, but they should not independently dictate containment or review levels. The final policy must preserve site-specific and experiment-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations. This aligns with Section V-E of the draft policy, which explicitly acknowledges that Risk Groups and Biosafety Levels are related but non-equivalent concepts.
b. Critique of Mandatory IBC Petitions for Emerging, Novel, or Unlisted Agents (Section III-B)
i. The 'IBC Functions' section (fifth bullet) directs the IBC to petition NIH to determine the minimum

biocontainment level for emerging, novel, or zoonotic agents 'for which the RG classification or containment level is not available in the BMBL,' prohibiting IBC approval until authorized by NIH and any other applicable entities.
ii. Terminology Inconsistency: The draft text treats 'RG classification' and 'containment level' as alternative terms residing in the BMBL. However, Section V-E correctly states that RGs and BSLs are non-equivalent. NIH must use these terms consistently across all policy sections.
iii. BMBL Functionality & Misconception: The Biosafety in Microbiological and Biomedical Laboratories (BMBL) manual does not assign Risk Groups; it provides Agent Summary Statements with recommended Biosafety Levels. A regulatory condition referring to an RG classification 'in the BMBL' cannot be fulfilled.
c. Jurisdictional Ambiguity: The phrase 'and any other applicable Federal, State, or local entities' introduces immense ambiguity. NIH must explicitly identify these entities, specify whether approvals are sequential or concurrent, clarify coordination protocols, and establish resolution pathways when determinations conflict.
d. Overbroad Scope & Unintended Petition Backlogs: As written, the petition requirement could be interpreted as applying to non-pathogenic genetically modified constructs or benign RG1 organisms that are not explicitly named in the BMBL. NIH must explicitly clarify that unlisted, non-pathogenic RG1 agents do not require federal petitioning.
e. Reusable Determinations & Response SLAs: Section III-D commits NIH to publishing determinations for lowering RG3/RG4 containment but omits determinations for emerging or novel agents. NIH should publish all containment determinations (agent, modification, approved containment, and rationale) in a searchable public database that other institutions may rely upon as established precedent. Furthermore, NIH must set a target response timeline (e.g., 30 calendar days) rather than relying on the subjective term ”timely.”
f. Definitive Source for Risk Group Assignments
With Risk Group assignments removed from the former Appendix B and absent from the BMBL, NIH must provide an authoritative, version-controlled federal repository or clear objective criteria for assigning Risk Groups to non-recombinant agents. Without standardized federal classifications, institutions will reach conflicting conclusions for the same agent, compromising national oversight consistency.
g. Avoid Rigid Containment Prescriptions (GDMOs and Influenza Research)
Rigid, one-size-fits-all containment rules conflict with performance-based risk assessment. A universal minimum of BSL-2 for Gene Drive Modified Organisms (GDMOs) does not map effectively to specialized containment systems (e.g., Arthropod Containment Level [ACL] guidelines, USDA/NCAR Greenhouse standards, or aquatic facilities). NIH should permit equivalent risk-based containment modalities and issue specialized guidance. Additionally, containment mandates for influenza constructs should specify exact phenotypic traits, host range, and pathogenicity markers rather than sweeping in constructs based on raw genomic segment proportions.

The draft policy treats Risk Groups (RGs) as mandatory containment triggers rather than hazard descriptors, so NIH should explicitly confirm in Section V-E that RGs do not independently dictate BSLs and preserve local risk assessment. The draft also cites RG lists in the BMBL, which do not exist, and lacks scope limits on petitioning, so NIH should correct the BMBL reference and exclude non-pathogenic RG1 agents from mandatory federal petitioning. In addition, the draft makes no commitment to publish determinations for novel or emerging agents, so NIH should publish all containment decisions in a

searchable public database with a 30-day target review timeline. Finally, the draft applies a universal BSL-2 to GDMOs and rigid segment ratios to influenza, so NIH should allow specialized containment (ACL, greenhouse, and aquatic) and calibrate influenza rules to phenotype.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.
a. Refine the definition of a reportable incident and provide clearer thresholds for reporting to support a risk-based, consistent approach across institutions. Clear thresholds improve consistency and allow NIH to focus regulatory oversight on events with true potential public health or community significance.
b. Decouple Regulatory Reporting from Public Website Posting: Requiring institutions to publicly post unredacted investigative reports and meeting minutes for routine or minor incidents creates severe unintended consequences:
i. Publicly posted incident reports inadvertently provide sufficient detail to identify involved personnel.
ii. Publicly linking Principal Investigators, grant numbers, and specific facility locations exposes researchers to harassment, physical threats, and targeted cyber-attacks, particularly in sensitive animal research domains.
iii. Aggregated public postings reveal institutional research security information. Automated AI scraping tools can harvest these public records to map national high-consequence research capabilities, directly conflicting with federal research security directives and Select Agent regulations.
iv. Forcing minor, fully mitigated events into public view suppress internal reporting of near-misses and borderline events out of fear of public backlash or reputational damage.
c. Resolving Undefined Categories & Technical Definitions: To eliminate ambiguity, prevent administrative overload, and protect local reporting culture, NIH must establish precise definitions for the following core terms in Section II:
i. Incident: A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.
i. Release (Loss of Containment or Occupational exposure): Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
ii. Basic First Aid vs. Agent-Specific Medical Treatment: NIH must explicitly align medical treatment with OSHA standards (care beyond basic first aid). NIH must clarify that precautionary, non-specific post-exposure prophylactic (PEP) treatment or routine medical consultations do not constitute agent-specific treatment triggering 24-hour federal reporting.
iii. Potential Exposure: Must be defined as an event occurring in the active presence of a biohazard where primary barriers or PPE were breached, creating a credible exposure pathway. Equipment or PPE failures occurring in the absence of active biohazardous agents are not potential exposures.
iv. Compliance Violation vs. Administrative Non-compliance: Must distinguish administrative non-compliance (e.g., late paperwork, minor log errors) from substantive biosafety non-compliance (e.g., unapproved research initiation or unauthorized containment lowering). Administrative non-compliance and low-risk items must NEVER necessitate a 24-hour reporting timeframe.
v. Minor Spill: Must remove subjective terms like generally and define minor spills.

d. Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries.
i. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

6. Other feedback relevant to this resource: 6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.
a. Provide risk assessment guidance for self-aggregating proteins (Policy Sections II and V-A). The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.
b. Clarify oversight of computational and AI assisted work (Policy Sections II and V-C). Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.
c. Provide a minimum 24-month phased implementation period The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.
d. Pilot the policy and templates: NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.
e. Develop implementation resources: Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.
f. Address the cost of compliance: The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.
g. Allow flexible institutional models: The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and

specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

393. ATCC (American Type Culture Collection)

I am responding: On behalf of an organization

Name: Heather Couch

Name of Organization: ATCC (American Type Culture Collection)

Type of Organization: Non-Profit Research Organization

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biological resource centers, culture collections, and repository operations handling biohazardous and genetically modified materials, including microbial strains, cell lines, and nucleic acid preparations used for authentication, production, quality control, and distribution rather than investigator-driven research.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Yes. The draft is written for investigator-driven research protocols and does not address biological resource centers, culture collections, repositories, or the production, quality-control, and distribution activities those organizations perform. “Biomedical research” is tied to the NIH mission but gives no operational test for a mixed-function organization to determine whether a given activity is covered. As a result, routine accessioning, preservation, authentication, standardized characterization, production, storage, and distribution become ambiguous the moment the material is a biohazard or has been genetically modified, even when no new scientific knowledge is being generated.

ATCC recommends that NIH adopt an activity-based scope test: define covered research by the purpose and design of the activity, treating work intended to generate generalizable scientific knowledge as research, while routine repository, production, diagnostic, quality-control, regulatory, commercial-service, storage, and distribution activities conducted under established procedures should not automatically become research solely because of the material’s hazard or modification status. NIH should expressly exclude routine operations conducted under established procedures unless the work is designed to generate new scientific knowledge, and should clarify that activities falling outside the policy’s research scope remain subject to applicable occupational safety, select-agent, transportation, environmental, public-health, quality-system, and institutional biosafety requirements, so excluding an activity from IBC research review does not mean it is unregulated.

NIH should also provide worked examples distinguishing routine repository operations (receipt, accessioning, preservation, authentication, sequencing, quality-control testing, production, and distribution of a deposited strain) from a distinct research project using that material to answer a scientific question, and should clarify when funding relationships (awards, subawards, contracts, collaborations, or service arrangements) trigger applicability in a mixed-function organization.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Review requirements should track the hazard of the resulting material and the proposed activity, not genetic-modification status alone. Relevant criteria include pathogenicity, transmissibility, replication competence, host range, route of exposure, scale, aerosol-generating procedures, environmental persistence, countermeasures, and biological and physical containment. A documented risk-reducing modification (attenuation, replication deficiency, chemical mutagenesis) should make a derivative eligible for the same or a lower review pathway than its wild-type parent, consistent with the draft's own requirement to evaluate how a modification changes risk factors.

ATCC recommends a tiered structure: full IBC review for activities presenting credible, unresolved, or higher-magnitude hazard; delegated review, conducted by the BSO or qualified biosafety staff with defined documentation and conflict-management standards, for activities with established risk profiles or minor amendments; and defined activity-, SOP-, platform-, or facility-based authorizations for routine work conducted within specified material, manipulation, and containment boundaries, with escalation whenever an activity exceeds those boundaries. This same calibration should extend to natural isolates, type strains, taxonomic reclassifications, primary cells, well-characterized cell lines, nucleic acids, inactivated materials, and sequence-derived records, each of which needs clear criteria to prevent inconsistent or unnecessary escalation.

On renewal and monitoring, NIH should clarify that unchanged, lower-risk activities with no significant incidents may use delegated rather than full convened review, and should let institutions rely on existing routine biosafety inspections, facility certification, and quality-system review rather than imposing duplicative IBC-specific inspections.

3. Continued utility of Risk Groups: Risk Group and containment should stay distinct: Risk Group informs the hazard assessment; containment (BSL) should reflect the actual proposed activity. A taxonomic name change shouldn't reset a prior Risk Group determination absent new hazard evidence.

The draft's definition of genetic modification includes stable alterations introduced through passaging, reassortment, and chemical or radiological means. Read with the tiering provisions, this can place an attenuated or otherwise risk-reduced derivative into a higher review category than its wild-type parent, which is inconsistent with the draft's own instruction to evaluate how a modification changes pathogenicity, transmissibility, host range, and other risk factors.

ATCC recommends that NIH keep Risk Group and containment conceptually distinct: Risk Group should inform the hazard assessment, while containment (Biosafety Level) should reflect the proposed activity and the resulting material's actual risk profile, not an automatic function of the parent organism's classification. NIH should specifically clarify the review pathway for attenuated, replication-defective, passage-derived, chemically mutagenized, and vaccine-seed materials, basing the review category on pathogenicity, transmissibility, replication competence, host range, exposure route, scale, and containment rather than genetic-modification status alone. The final policy should avoid categorically excluding all RG1-related work from flexibility; instead it should provide clear low-risk criteria and proportionate delegated review where the evidence supports it.

This same misalignment risk applies to taxonomic reclassification: a name change should not by itself

make a previously evaluated organism administratively "unlisted," so NIH should maintain a living classification resource and carry forward the prior Risk Group assessment after a name change unless new hazard evidence warrants reassessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary adoption will depend on the policy being genuinely usable outside the NIH-funding context it was designed for. Non-funded institutions are more likely to adopt the framework voluntarily if NIH publishes the same decision tools it owes funded institutions: scope and tiering decision trees, standard risk-assessment and delegated-review templates, model IBC policies and redaction standards, and searchable precedent determinations tied to specific materials and activities rather than organism names alone.

Reliance and reduced duplication are strong incentives. NIH should clarify when another federal agency's approval (CDC, FDA, USDA, DoD, Federal Select Agent Program) substitutes for or avoids duplicative federal review, and should permit institutions to use integrated governance and review workflows that satisfy multiple applicable policies, including the July 28, 2026 United States Government Policy for Stopping High-Risk Life Sciences Research, without duplicative committees, risk assessments, records, or annual reviews. A non-funded institution is far more likely to adopt NIH's framework voluntarily if doing so also satisfies its other federal and customer-driven obligations rather than adding a parallel compliance burden.

Finally, NIH could offer recognition or safe-harbor value, such as treating voluntary conformance as evidence of due diligence in federal procurement, grant eligibility, or partnership decisions, and could extend access to the National Biosafety Data and Safety Analysis Center's de-identified learning outputs to voluntarily participating institutions, giving them a direct benefit (shared incident learning and precedent) in exchange for adopting the practices.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The templates should define objective, bright-line thresholds for what constitutes a reportable incident (laboratory-acquired infection, community risk, loss of containment, release, exposure, agent-specific treatment versus basic first aid, equipment failure, inventory or security issues with public-health consequences) so that routine alarms, precautionary consultations, or equipment faults that triggered no credible exposure or release do not automatically require a federal report. The reporting template should distinguish precautionary notification from a confirmed reportable incident, and should allow institutions to supplement, correct, close, or withdraw an initial notice after investigation, with a visible, auditable amendment history rather than treating every initial report as final.

For public posting, ATCC recommends a two-layer approach for both templates: a complete, access-controlled version containing full provenance, evidence, and rationale, and a public-facing version using standardized permitted redactions for confidential commercial information, depositor and customer identities, personally identifiable and occupational-health information, facility configurations and security vulnerabilities, and information that could facilitate misuse. For meeting minutes specifically, the template should allow delegated-review approvals to be reported by neutral protocol identifier, review category, decision, conditions, and date, rather than reproducing the complete confidential record, and should not make public access to meetings the default where proprietary, security-sensitive, or active-

investigation matters will be discussed.

For the National Biosafety Data and Safety Analysis Center, NIH should limit mandatory institutional posting to incidents of confirmed public-health or environmental significance, use de-identified national summaries for lower-risk events, allow delayed publication during active investigations, and provide correction and appeal procedures. A safe harbor for good-faith redaction decisions made under NIH's own standards would reduce institutions' administrative and legal exposure without reducing transparency where it matters.

6. Other feedback relevant to this resource: The six-month effective date is insufficient for institutions to identify newly covered activities, revise policies and charters, recruit and train IBC members, establish delegated review, convert registrations, implement public-facing websites and redaction procedures, build incident workflows, and submit a Biosafety Assurance. ATCC recommends at least an 18-month phased implementation period, with additional time for converting legacy activities, and a documented transition mechanism that lets work appropriately authorized under prior institutional requirements continue while that conversion occurs.

The most valuable resources NIH could provide are: scope and tiering decision trees (including the activity-based test for distinguishing research from routine repository, production, and distribution work); standard risk-assessment, delegated-review, incident-assessment, and Biosafety Assurance templates; model IBC policies, redaction standards, renewal criteria, and post-approval monitoring approaches; training for IBC members, BSOs, investigators, and institutional officials; worked examples specific to repositories, core facilities, contract laboratories, manufacturing support, quality control, and distribution, since the current draft materials are written almost entirely around investigator-led research protocols; and a searchable FAQ and precedent registry with persistent identifiers, current and former taxonomic names, material identifiers, evidence considered, and assigned containment, so determinations can be reused rather than re-litigated at each institution. NIH should also publish an administrative-burden analysis and guidance on allowable implementation costs, and should clarify BSO qualification standards so that demonstrated biosafety knowledge, experience, and training, not degrees or credentials alone, are recognized as sufficient.

Description: ATCC Technical Public Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice NOT-OD-26-112). This document provides detailed recommendations on defining the boundary between covered research and biological-resource-center operations; calibrating oversight to risk; treating emerging, novel, and taxonomically reclassified agents and type strains consistently; aligning Risk Group classification with containment for genetically modified and risk-reduced agents; defining primary cells and well-characterized cell lines; using genomic evidence appropriately; clarifying nucleic acids, inactivated materials, and digital sequence records; protecting confidentiality and security in public transparency mechanisms; defining delegated review, renewal, monitoring, and amendment processes; setting objective incident-reporting thresholds; reducing duplication with other federal oversight; and providing a realistic transition period and implementation tools.

394. Medical College of Wisconsin

I am responding: On behalf of an organization

Name: Nathan Berken

Name of Organization: Medical College of Wisconsin

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): The Medical College of Wisconsin (MCW) appreciates the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. MCW supports NIH's goals of modernizing biosafety oversight, reducing burden for low-risk research, and aligning Institutional Biosafety Committee (IBC) practices with the IRB and IACUC models. The comments below follow the topics identified in the Request for Comment. Within each topic, MCW offers a brief summary of its perspective, followed by specific observations and questions that we hope will help bring greater clarity to the final policy. MCW thanks NIH for considering these comments and would welcome the opportunity to provide further input as the policy and its implementation resources are developed.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Summary: MCW supports a broader, risk-based scope for biosafety oversight. In reviewing Sections II, III-A and III-B, our analysis identified several areas where additional definition or clarification would help institutions apply the policy consistently. These include how the policy's scope relates to clinical settings, how "biohazard" is defined, which institutions are covered by the "any NIH funding" provision, the role of the Biological Safety Officer (BSO) at BSL-2, and the incident reporting and public posting expectations. Several of these provisions may add administrative burden without a corresponding biosafety benefit, and some raise privacy considerations. As MCW reviewed this portion of the rule, our analysis raised questions that could help inform greater clarity within the rule, such as:

- Scope and clinical settings: The scope is defined as "all biomedical research, in lab settings, involving biohazards," while the definition of "Laboratory research" includes clinical settings. MCW would welcome clarification of how clinical settings are intended to be treated, as the current terminology may be read in more than one way.

- Definition of biohazard: The policy refers to "biohazards" but does not define the term on its own. MCW suggests NIH consider revising the definition of "Biological agent" to be neutral, and adding a risk-based definition of "biohazard" or "biohazardous agent."

- Institutions with other NIH funding: The policy applies to NIH-supported research and to non-NIH-funded research at any institution that receives NIH funding. Could NIH clarify whether this includes

institutions that do not receive NIH funding for research involving biohazards but do receive NIH funding for other research?

- Record retention: Retention of IBC records is tied to funding requirements. Would NIH consider allowing IBC record retention to stand on its own, based on the IBC records themselves rather than on the funding associated with a given protocol?

- BSO at BSL-2: A BSO is required only for BSL-3/BSL-4 and GDMO research. Could NIH share the rationale for not requiring a BSO at BSL-2, given that most institutions conduct BSL-2 work, and clarify expectations for how those institutions should designate this function?

- Periodic review of approved research: Section III-B calls for the IBC to "periodically review approved research to ensure compliance." Is this intended to refer to the de novo review of a protocol every three years, or to a post-approval monitoring program similar to that used by IACUCs? How does it relate to the BSO's responsibility to conduct periodic inspections?

- Compliance violations as reportable incidents: Compliance violations (for example, failure to obtain or maintain IBC approval, or failure to obtain NIH approval to lower biocontainment) are grouped with incidents that pose a significant risk to human health, which triggers 24-hour notification and public posting. Because these are compliance matters rather than health-risk events, MCW asks whether NIH would consider placing them in a separate reporting category without the 24-hour timeline or public posting.

- Animal bites and scratches at BSL-1/ABSL-1 and BSL-2/ABSL-2: As written, the policy appears to direct routine animal bites, scratches and similar events to the IBC. MCW notes that these events are typically managed effectively through Environmental Health and Safety, occupational health and animal facility staff, and asks whether NIH would consider allowing those channels to handle them, reserving IBC involvement for events with a clear biosafety nexus.

- Privacy: Public posting of incident reports could unintentionally compromise the privacy of affected staff. What safeguards or redaction expectations does NIH anticipate?

- Occupational health and safety program (OHSP): Section III-A states that an OHSP, if needed, "should be maintained as part of the overall biosafety program." Are there specific OHSP requirements under this policy, or is the intent to rely on existing regulations and institutional programs?

- Delegated reviewer (Section IV-3): Is the individual to whom review and approval may be delegated defined? Can this be the BSO? Must it be an IBC member other than the BSO? Or is this left to the institution to determine?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Summary: MCW supports the tiered approach to oversight and the opportunity it creates to focus committee time on higher-risk research. Our review of Section IV identified places where category definitions overlap or are broad enough that institutions may apply them differently, and where a distinction between basic and clinical research could further improve efficiency. Clearer examples, defined terms and a narrower

federal trigger would help institutions calibrate oversight to risk and reduce the likelihood that low-risk, well-understood work is routed to full committee or to NIH. As MCW reviewed this portion of the rule, our analysis raised questions that could help inform greater clarity within the rule, such as:

- Terminology: MCW supports the tiered review model. Would NIH consider using "Designated Review" in place of "Delegated Review," which would be familiar to the research community from IACUC and IRB practice?

- Authority of the IBC and reviewers: It would be helpful if the policy stated plainly the full scope of IBC authority, including whether the IBC may disapprove research and request modifications to secure approval. Does a delegated or designated reviewer hold the same authority, or must certain determinations (such as disapproval) be referred to the full committee?

- Clinical research under Section IV-3: As written, Section IV-3 appears to treat clinical and basic research the same way, which would appear to preclude delegated review of clinical studies involving widely used therapeutics, such as CAR-T and other genetically modified, long-lived cell products that have already undergone substantial biosafety evaluation and have been used to treat tens of thousands of patients. MCW suggests NIH consider allowing delegated review for clinical studies, or at a minimum a carve-out for studies involving investigational products that are substantially similar to currently approved products. This could improve throughput and flexibility and support more timely access to new therapies.

- Section IV-1 trigger for NIH approval: Requiring NIH approval whenever an emerging, novel or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents that are routinely handled at BSL-1 and BSL-2 (for example, organisms identified in environmental screens). MCW suggests NIH consider defining the trigger narrowly, permitting qualified IBCs to make interim or final determinations for well-characterized agents, and reserving NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

- Genetically modified materials under Section IV-2: This category is broad and could encompass many standard, low-risk experiments. Could NIH clarify whether it includes transgenic animal tissue, HEK cells, plasmids administered to cells, or cells already modified by a vendor?

- Primary cells under Section IV-2: "Research with primary cells that may be contaminated by adventitious agents" appears to relate to bloodborne pathogen risks that many institutions review outside of full-committee meetings. Could NIH clarify whether this includes all human cells, or any cell permissive to a human pathogen?

- Overlap between Sections IV-2 and IV-3: Genetically modified cells, viruses and organisms appear in IV-2 (full IBC review), while subsets of the same materials appear in IV-3 (delegated review). More precise delineation between the two would help avoid inconsistent application.

- "Well-characterized cell lines": Will NIH provide examples, or is this determination left to the

institution?

- Plasmids and viral vectors: Research with "plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes" is placed in IV-3. MCW suggests NIH consider retaining replication-incompetent, non-integrating viral vectors in IV-3 while moving plasmids expressing reporter or low-risk transgenes to an exempt category. Will NIH provide examples of "low-risk transgenes"?

- Transgenic organisms at BSL-1/ABSL-1: Could NIH clarify what is meant by "transgenic organisms," including whether this covers transgenic rodents, Drosophila and USDA-regulated species? If so, does it extend to breeding or purchase and transfer of transgenic rodents, activities that were previously exempt?

- Genetically modified RG1 agents: Does this category include E. coli and S. cerevisiae used for plasmid propagation or protein expression?

3. Continued utility of Risk Groups: Summary: MCW finds the Risk Group information in the current NIH Guidelines valuable when assessing biological agent risk, and it works well alongside the biosafety level guidance in the BMBL. We encourage NIH to retain RGs as a baseline for risk assessment. Because the draft policy relies on RG classifications in several places, timely access to the supplemental RG materials NIH has described will be important for institutions preparing to implement the policy. As MCW reviewed this portion of the rule, our analysis raised a question that could help inform greater clarity within the rule:

- Timeline for RG materials: The policy notes that NIH intends to provide supplemental materials on RG classifications. Does NIH have an approximate timeline for making these available?

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): n/a

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Summary: MCW supports transparency and consistent documentation of IBC activity. However, our review suggests that required templates, accelerated approval timelines and broad public posting of incident reports could create significant operational burden, particularly for institutions using electronic protocol systems, and could unintentionally discourage full reporting by investigators. MCW offers alternatives that we believe would meet NIH's transparency and oversight goals while allowing institutions flexibility in how they document and communicate this information. As MCW reviewed this portion of the rule, our analysis raised questions and suggestions that could help inform greater clarity within the rule, such as:

- Meeting minutes template: Many institutions use electronic systems, and a required template would likely necessitate substantial programming changes. MCW suggests NIH consider specifying the elements that minutes must include and allowing institutions to develop their own format. This would also bear on the realism of the proposed six-month implementation period.

- Timing of minutes approval: Requiring approval no later than the next convened meeting may be difficult in practice. Many IBCs allow members to request changes before voting, which can mean

minutes are approved at the following meeting. Would NIH consider a more flexible timeframe?

- Public posting and PI and grant information: Including the PI name and grant number is appropriate for reports submitted to NIH, but MCW suggests that this information be redacted when reports are publicly posted. More broadly, MCW believes public posting of all incident reports may be unnecessary. As an alternative, institutions could describe their incident reporting procedures in the Biosafety Assurance, submit the appropriate incidents to NIH, and maintain internal records of all others.

- 24-hour reporting: Immediate reporting within 24 hours may not be necessary in most cases. MCW suggests NIH consider allowing institutions to address the situation first and then file a report that includes the resolution.

6. Other feedback relevant to this resource: Summary: MCW anticipates that implementation will require substantial effort, including converting existing protocols, updating electronic systems and obtaining an approved Biosafety Assurance before research can proceed. Our principal requests are for a longer implementation period, an opportunity to review and comment on the Assurance template, and clarification of several terms (externally administered IBC, non-affiliated member, minor amendment) that will directly affect how institutions structure their programs. We also share concerns about the scope of public posting, and we suggest a model based on the Animal Welfare Assurance that we believe would meet NIH's goals with less burden. As MCW reviewed this portion of the rule, our analysis raised questions that could help inform greater clarity within the rule, such as:

- Implementation timeline: A six-month implementation period appears insufficient given the hundreds of protocols to be converted and the time needed to obtain an approved Assurance. MCW recommends at least 18 months, although three years may be more realistic given the approval period and scope of changes.

- Biosafety Assurance template: The draft refers to a "Biosafety Assurance" and its general content. MCW would appreciate a template and an opportunity to comment on it. Will it be structured similarly to an Animal Welfare Assurance, and will review be comparable? What is meant by "Other pertinent information requested by NIH"?

- Public posting of information: MCW is comfortable providing the requested information in an Assurance. We have concerns, however, about publicly posting some of it on a website, as this is not required for IACUCs. MCW's procedures are available on an intranet for the benefit of investigators and staff. Incident reports that are not required to be submitted to NIH should not need to be included, and we are concerned that posting incident reports in general may create a punitive atmosphere that could interfere with full reporting by investigators. Describing the institution's incident reporting procedure in the Assurance would, in our view, give NIH appropriate assurance that the procedure is in place.

- Externally administered IBC and multiple sites: Could NIH clarify the term "externally administered IBC" and whether each site must have its own IBC of record and its own Biosafety Assurance? MCW suggests NIH consider allowing a single local IBC to serve multiple local locations under one Assurance, provided the covered components are clearly stated. This approach is similar to how Animal Welfare Assurances are handled, would not extend to commercial IBCs, and would meaningfully reduce administrative

burden for local IBCs.

- Non-affiliated members: Could NIH provide a definition of "non-affiliated" member? MCW suggests using the same definition that applies to IACUCs.

- Minor amendments: Could NIH define "minor" amendment, or confirm that institutions may define it by policy and state that definition in their Biosafety Assurance?

Description: Extended comments to revised NIH Biosafety policy

October 19, 2026

RE: Comments for the Draft NIH Biosafety Policy for Research Involving Biohazards (Request for Comment – NOT-OD-26-112, dated August 19, 2026)

To whom it may concern,

I am an associate professor that has been teaching and conducting research in infectious and vector borne diseases for the past 28+ years. Before then, the focus of my Ph. D. dissertation research was pathogenic bacteriology. During my career I have published multiple articles on vector-borne diseases and have presented my research and national and international meetings. I have also worked closely with the regulatory and biosafety groups at my institution, so I have some experience with the current and past regulations. My comments regarding the Draft NIH Biosafety Policy for Research Involving Biohazards (the Policy) (NOT-OD-26-112, dated August 19, 2026) are below.
In general, I support the replacement of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines). However, I have concerns about the Policy, including the scope, definitions, and tiers of oversight, which are described further below.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.
   a. Increased Administrative Burden: The draft policy requires Risk Group assignments for non-recombinant agents, creating additional administrative workload for institutions.
   b. The proposed Policy uses words/terms but does not define them; some of these did not have definitions in the *NIH Guidelines*, and therefore this is a good opportunity to define these listed below:
      i. Organism
      ii. Transgenic
      iii. Adventitious agent
      iv. Virus as a "living organism"

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).
   a. **General Definitions: *Toxin***
      i. The definition of toxin is poor. Clearly state that "living organism" does not include viruses.
      ii. Alternatively, adopt a clearer definition. For example, ISO35001 uses "substance, produced by plants, animals, protists, fungi, bacteria, or viruses, which in small or moderate amounts produces an adverse effect in humans, animals, or plants. This includes substances and

materials, natural or as a result of biotechnology, that may contain toxins, any poisonous substance or any poisonous isomer, homologue, or derivative of such a substance."

b. **Section IV-1 (Research that Requires NIH and IBC Approval Before Initiation):** ***Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL.***
   i. For researchers who identify new biological agents, there is no path to work with these agents. Once identified as an "emerging agent" with no risk group or biosafety level recommended in the BMBL, the research must be approved by NIH. However, without the ability to work on the agent, the researcher cannot generate the data required for NIH to conduct the risk assessment.
      1. **I recommend** that an initial characterization be allowed with the results to be shared with NIH to determine the appropriate Risk Group level.
   ii. Upon the Implementation Date of this Policy, what is the expectation for research with the many agents (especially bacteria and fungi) that are not listed in the BMBL, and are typically handled at BSL1 or BSL2?
      1. Are researchers expected to have obtained approved from the NIH by the Implementation Date? Does NIH OSP have the personnel to review and approve the requests that they will be inundated with?

c. **Section IV-2 (Research That Requires IBC Review and Approval Before Initiation):** ***Research involving RG3 or RG4 wild-type biological agents.***
   i. No comments on this section.

d. **Section IV-2:** ***Research with primary cells that may be contaminated by adventitious agents.***
   i. As noted above, the Policy does not define adventitious agents. Therefore, entities will be uncertain how to comply with this regulation.
   ii. If the intention of the Policy is to regulate primary cells that may be contaminated by bloodborne pathogens:
      1. **We recommend that:** This should not be regulated by this Policy as long as the entity is complying with OSHA Bloodborne Pathogens Standard or its equivalent.
      2. **We recommend that:** If it must be regulated by this Policy, it should not fall under the category of requiring IBC approval and should at most be in Section IV-3, where delegated review is permitted.
   iii. If the intention of the Policy is to regulate primary cells that may be contaminated by any unknown biohazard (including clinical or field samples):
      1. The recommendation is that the sample undergoes genetic testing and analysis initially or is characterized at high or maximum biocontainment.

e. **Section IV-2:** ***Research with wild type or genetically modified RG2 biological agents for which lower containment is requested, or research with wild type or genetically modified RG3 or RG4 biological agents that NIH has previously approved to be conducted at lower containment.***
   i. The Policy implies that there will be a workflow of (1) an entity submits an initial request for NIH to lower containment involving wild type or genetically modified RG3 or RG4 biological agents, (2) NIH will make a determination on whether that lower containment is

appropriate, (3) NIH will be responsible for publishing approved determinations of appropriate lower containment for these agents, (4) subsequently, research involving these agents may be approved by the IBC alone (without NIH approval).

1. This workflow should be expressly stated in the Policy to minimize confusion. This includes a clear statement that once NIH has made the determination and published it, other entities will not be required to obtain NIH approval.
2. The method by which NIH will publish these determinations should be described, including the minimum time frame (e.g., determinations will be published within 3 months).
3. The Policy should be clear on how much information will be released with these determinations (will it include information that will make sensitive information readily available to foreign adversaries?)

f. **Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): *Research conducted with transgenic organisms at BSL-1/ABSL-1.***

i. The purchase and transfer of transgenic rodents requiring BL1 containment is exempt (Appendix C-VII). Further, the generation of BL1 transgenic rodents (Appendix C-VIII) is exempt in the NIH Guidelines. In 2011, NIH deemed that "… these breeding experiments do not pose an appreciable risk to human health or to the environment. In addition, while registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk." (January 19, 2011, Federal Register, January 19, 2011 (76 FR 3150)). As documented in NIH guidance documents, the subsequent use of these BL1 transgenic rodents is also exempt (https://osp.od.nih.gov/wp-content/uploads/2022/11/Animal_Activities_Table.pdf). The same risk assessment should apply today, and the Policy should not require that work with transgenic rodents that can be housed at ABSL1 be approved by the IBC.

ii. As noted previously, there is no definition of *organism* in the Policy. Therefore, we recommend changing this to *animal* in this section.

iii. We understand that research with other transgenic animals has not had the time to demonstrate the same safety track record as transgenic rodents and therefore should continue to require IBC approval before that research is conducted.

iv. **We recommend that this be re-written** as: Research conducted with transgenic animals at BSL-1/ABSL-1, other than transgenic rodents.

g. **Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): *Research with genetically modified RG1 biological agents.***

i. Certain research (not requiring NIH-OSP approval and not involving DNA from RG3, RG4, or restricted organisms) with specific risk group 1 biological agents is exempt in the Guidelines (Appendices C-II, C-III, C-IV, and C-V), having been determined by the NIH Director to not present a significant risk to health or the environment. The Category here (research with genetically modified RG1 biological agents) is in contradiction to this

determination and would require that work that was previously exempt now require IBC approval.

ii. **We recommend that this category be re-written as:** Research with RG1 biological agents is exempt as stated under the current policy.

h. **Several sections, including Section IV-2: *Research involving genetically modified cells, viruses, or organisms, other than plants (e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs)* and Section IV-3: *Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes***

i. An exemption for recombinant DNA molecules containing less than one-half of any eukaryotic viral genome that are propagated and maintained in tissue culture has existed at least since the Federal Register Notice in 1995 (Effective June 24, 1994, Published in Federal Register, July 5, 1994 (59 FR 34472)). The NIH Director has therefore determined that such experiments do not present a significant risk to health or the environment. While a single researcher registering for this work would not be a significant burden, the total number of registrations will constitute a significant collective administrative burden on the IBC and researchers that is not commensurate with the very low biosafety risk.

ii. We recommend that an exemption be added.

i. **Section IV-3: *Research with biological toxin proteins not on the Select Agent list.***

i. The policy needs to be written clearly and concisely, which this category does not accomplish. As written, this would include food allergens, since they cause harm to humans, yet there is no indication that this is intended.

ii. **We recommend that this be re-written as:** Research with biological toxin proteins with an LD_{50} in vertebrates of <100 micrograms per kilograms of body weight.

iii. Additionally, a list of toxins currently classified under this category should be provided in the Policy.

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

a. Risk Group assignments have been removed from the NIH Guidelines and are not comprehensively provided in the BMBL. NIH should provide a definitive source or clear criteria for assigning Risk Groups to non-recombinant agents. Without standardized Risk Group classifications, institutions may reach different conclusions for the same agent, reducing consistency across the research community.

b. Please provide the biosafety rationale and supporting evidence that prompted the inclusion of additional oversight requirements for research involving insect cell lines, non-human/NHP cell lines, and pathogens that are not capable of causing disease in humans, including immunocompromised individuals. Clarification of the specific risks, incident history, or emerging concerns that necessitate these requirements would help the research community

understand the basis for the policy change and assess whether the proposed oversight is proportionate to the actual biosafety risk posed by these systems.

c.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
   a. Additional clarification is especially in consideration of collaborations and/or contracts between non-NIH funded and funded institutions.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.
   a. The proposed definition of an incident appears overly inclusive and may capture events with minimal biosafety significance. A broad incident definition could result in unnecessary reporting requirements, diverting resources from investigating and addressing more consequential biosafety events.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.
   a. Refine the definition of a reportable incident and provide clearer thresholds for reporting to support a risk-based, consistent approach across institutions.

7. Other Comments
   a. The responsibilities of the institution (Section III-A) includes the following text (emphasis added) regarding records retention:
      The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states "the recipient and subrecipient must retain all Federal award records for **three years from the date of submission of their final financial report**."
      i. The Policy is assuming that all IBC records are from projects that are NIH funded. The Policy has failed to consider projects that are not NIH funded and therefore will never submit a final financial report. As written, such IBC records may never be disposed of, which is either an oversight or egregious regulatory overreach. **This language needs to be changed.**
      ii. We recommend the following language:

      The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states "the recipient and subrecipient must retain all Federal award records for three years from the date of submission of their final financial report." In the case of IBC records unrelated to Federal awards or where a final financial report is not submitted, it is unclear if documentation must be maintained for 1 year after IBC approval expires. This point need clarification.

8. Research with primary cells that may be contaminated by adventitious agents.
   a. Provide a definition of adventitious agents.
   b. Provide rationale on why primary cells require full IBC review, when wild-type (RG2/BSL2) agents can be reviewed through delegate review. The bulk of adventitious agents are categorized as risk group 2/BSL2 agents when isolated, cultured or purified, by definition this would imply that these agents can be reviewed and approved by delegate review.
   c. For known clinical samples of higher risk group agents (Brucella, Herpes B, Mtb) the BMBL recommends BSL-2 practices, containment equipment, and facilities are recommended for routine handling of clinical specimens of human or animal origin. Why can't delegate review be assigned to these types of samples, with caveat that if samples are positively identified and research will continue, then full IBC review will be required?
   d. Should this bullet be changed to highlight unscreened field or human samples from regions of endemic infections with RG3 and RG4 biological agents?

Reasons to remove from the scope of the Policy

- The work does not pose an appreciable risk to human health or to the environment.
- While registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk.
- Personnel who do not have access to biohazards, nor the ability to gain possession of biohazards, should not subject to the Policy. This is egregious regulatory overreach. As written, the individuals to whom this regulation will apply is broad and vague, which will lead to entities wasting time and effort to identify individuals, overtraining these individuals, and likely still being unable to fully comply with this poorly-written and obviously overreaching regulation. We strongly object to this requirement which will add significant burden to entity's without providing increased safety or security of biohazards.
    - What benefit is there in training an individual who performs administrative functions but does not have access to biohazards? How will training these individuals increase the safety or security of biohazards? This is a waste of resources with no clear benefit.
- Second, will entities be required to retroactively go back and add this information to their current inventory written records? How do the regulators expect this to be accomplished?
- This addition to the regulation will set entities up for failure, with no clear benefits to our biosafety programs.
- The Summary provided in the Policy does not provide an outlined justification for any of the following language changes to xxx. Thus, it is unclear why these changes are being proposed, how they will enhance the protection of human, animal, and plant health and safety, or how it will reduce the likelihood of the accidental or intentional release of a biohazard.

Issues to identify

- The definition is poorly written; regulatory language should be stated in clear, plain language. Such detailed examples should not be used in the regulatory language; if they are required, the original regulatory language is not sufficient and should be revised.
- Regulatory language should clearly and succinctly state a performance-based standard, which this definition fails to accomplish.
- Entities will be uncertain how to comply with this regulation, leading to chilling effects on the research community, additional administrative burden, and unintentional failures to comply.
- We recommend the following definition, based on xxx:
- The proposed definition removes the entity's ability to perform internal risk assessments to determine risk, thereby making all incidents involving biohazards reportable regardless of actual risk of escape and/or occupational exposure. The regulation must allow for the entity to perform risk assessments; it is important to recognize a risk assessment encompasses the whole picture of the event, not a single data point as these definitions imply. Risk assessments for events that may have resulted in an escape or potential occupational exposure are conducted within minutes to hours of potential exposure(s) and often incorporate a whole team of SMEs (biosafety, medical professionals, scientists, engineers) depending on the event to evaluate if the event resulted in escape of pathogen and/or if there was risk of occupational exposures.
- The additional reporting requirements will not enhance the protection of human, animal, or plant health and safety, reduce the likelihood of accidental or intentional release of a biohazard, or increase the probability that a release will be prevented from occurring.
- This change in definition will result in considerable administrative burden for entities with no real change in outcome or reduction in risk.
- Escape of a biohazard outside of primary containment should not require reporting unless a risk assessment has determined that the event resulted in a biohazard escaping beyond the defined biocontainment boundary (following the same definition in the FSAP HVAC policy statements) and/or causing an occupational exposure.

Good feedback

- This is a well written definition. Clear, concise, and with plain meaning. We support adding this definition to the regulations.

As stated previously, I support the replacement of the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines) as many of my colleagues do. However, there are several areas of ambiguity in the proposed Policy that could lead to confusion and an unintended massive increase in the burden placed on IBC and researchers which will have the chilling effect of hindering research progress. I don't believe that is the goal of this new Policy.

Thank you for your consideration.

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biological and Biomedical Research - all domains

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: FASEB, a federation of 21 member societies representing more than 100,000 biological and biomedical researchers, thanks NIH for taking on a need the research community has long recognized. The current NIH Guidelines were built around recombinant DNA, while the biological systems and hazards investigators work with today extend well beyond that frame. FASEB appreciates NIH's effort to modernize biosafety oversight and supports the development of a clearly defined, risk-based scope. A single framework addressing biohazards broadly is more coherent than a system in which similar risks may be treated differently based on whether a nucleic acid modification is involved.

FASEB nevertheless asks NIH to further refine the operative scope language before finalization. The threshold phrase "known or potential risk to human health" (Section II) is not sufficiently defined to support consistent application, and individual investigators, particularly trainees and early-career researchers establishing new laboratories, will depend on their local IBC to interpret it. Without additional guidance or illustrative examples, comparable protocols may be scoped differently across institutions, creating administrative burden that is not necessarily related to differences in actual risk. FASEB recommends that NIH supplement the final Policy with a non-exhaustive set of worked examples that would help investigators and IBCs apply the scope consistently.

FASEB also asks NIH to establish a defined transition period following the Policy's effective date. Investigators with active, multi-year awards that were initiated under the current framework should not be required to interrupt ongoing research or undertake retroactive registration without adequate time to assess and implement the new requirements. Full discussion, including specific examples, is provided in the attached letter.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): FASEB supports the introduction of delegated review (Section IV-3) as a meaningful mechanism for calibrating oversight to actual risk, and we appreciate that this pathway is not available under the current NIH Guidelines. For

individual investigators, however, the value of delegated review will depend on whether it provides a materially faster pathway than full-committee review. FASEB recommends that NIH establish an expectation for timely delegated determinations or require institutions to report delegated-review turnaround times so that the effectiveness of this new pathway can be assessed.

FASEB also asks NIH to clarify how amendments limited to a previously approved vector platform, such as testing a new transgene or therapeutic target within an already-characterized AAV or adenoviral system in preclinical models, should be reviewed. Without clarification, routine iterative testing could trigger disproportionate re-review relative to the risk involved. FASEB recommends that such payload-only changes be made explicitly eligible for delegated review consistent with existing categories under Section IV-3. Further discussion is provided in the attached letter.

FASEB is also concerned about the requirement that IBC approval expire after three years and be followed by a full de novo registration and review (Section III-B), regardless of whether the approved research has changed. For investigators working under longer award cycles or training grants, this could create recurring administrative requirements that are disconnected from changes in the underlying risk. FASEB recommends that NIH establish an abbreviated renewal pathway for protocols with no material changes, reserving full de novo review for research that has meaningfully changed in scope, agent, or risk profile.

FASEB recognizes the value of the transparency and accountability measures embedded in this structure. Our concern is that the administrative burden associated with implementing those measures should remain proportionate and should fall as lightly as possible on the investigators conducting the research.

3. Continued utility of Risk Groups: FASEB supports retaining Risk Groups (RGs) as the baseline framework for risk assessment. RGs are the framework most researchers encounter in biosafety training and in the BMBL's agent summary statements and related scientific literature. Replacing or subordinating RGs to BSL-based assessment alone would require the research community to adopt a different primary framework without a clear corresponding safety benefit.

FASEB asks NIH to strengthen guidance for the area the draft Policy identifies as particularly challenging: genetically modified, chimeric, and synthetic biology constructs for which no single parent RG readily captures the characteristics of the resulting system (Sections V-B and V-C). These cases require investigators to synthesize information about source agents, sequence function, biological context, and experimental use, yet many investigators will not have formal training in conducting this level of risk analysis. Worked examples would improve both the consistency of risk assessment and the efficiency of interactions between investigators and IBCs.

FASEB also asks NIH to ensure that the process for NIH-level risk determinations, required when an agent’s classification or containment level is not yet available in the BMBL, proceeds on a clear and predictable timeline, with provision for expedited handling when research responds to an emerging public health threat, such as a shift in hantavirus transmission patterns. Full discussion is provided in the attached letter.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): FASEB supports the creation of the National Biosafety Data and Safety Analysis Center (NBDSAC) and its explicit firewall against using voluntarily submitted near-miss data for enforcement or funding decisions. This is the kind of non-punitive reporting culture that meaningfully improves safety, and FASEB encourages NIH to promote it actively to investigators, in addition to institutions.

FASEB notes, however, one practical difficulty with the protection as drafted. It applies only if the incident did not result in an environmental release or a laboratory-acquired infection, but an institution deciding on whether to submit a near-miss report generally cannot know at that point whether either outcome will later materialize. That uncertainty could lead institutions and investigators to hesitate or to forgo reporting, which is the opposite of what the mechanism is meant to achieve. FASEB asks NIH to clarify how and when this condition will be assessed, and to consider whether the protection can attach to good-faith reports based on what was known at the time of submission.

FASEB raises a significant concern about the incident-reporting requirements as drafted. The required template mandates disclosure of the responsible PI's name in public, non-redactable incident reports, while other individuals involved are identified only by role or title (Appendix B; Section III-A). For an individual investigator, particularly an early-career researcher, this creates a permanent public association between the investigator and a reported incident regardless of the investigator's degree of involvement, fault, or the severity of the event. FASEB is concerned that this asymmetry could discourage the proactive reporting that the Policy is intended to promote. Further, the forms also requires public reporting of the grant number. While we understand the need to include this information for incident tracking, grant numbers allow access to PI names in the public-facing NIH databases and would therefore create the same challenges. NIH should reconsider whether public identification of the PI by name is necessary to achieve its transparency objectives, as distinct from the information NIH requires for internal oversight. FASEB welcomes further dialogue on approaches that preserve accountability without creating a disincentive to report.

On voluntary compliance for non-NIH-funded research, FASEB defers primarily to institutional and research-administration stakeholders that are better positioned to address adoption incentives. We note, however, that broader voluntary adoption will depend in part on whether the framework is viewed as practicable and proportionate to the safety benefit it provides. Further discussion is included in the attached letter.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: FASEB appreciates NIH's release of draft templates alongside the Policy and offers the following practical feedback from the investigator's perspective.

The draft IBC meeting minutes template effectively requires a public-facing, plain-language project description and risk assessment narrative for each registration, work that will often originate with the PI. FASEB recommends that NIH develop PI-facing guidance and model language, in addition to IBC-facing instructions, so investigators understand the expected level of detail and are not required to infer how technical information should be translated for a public audience.

FASEB also asks NIH to clarify the redaction standard. Both templates instruct institutions to redact private or proprietary information "judiciously" without further definition. This creates risks in both directions. Insufficient guidance could result in disclosure of technically sensitive construct or protocol details in permanent public records, while overly broad redaction could undermine the Policy's transparency objectives. FASEB recommends that NIH establish concrete redaction criteria, potentially in coordination with biosecurity expertise where dual-use considerations are implicated, rather than leaving this judgment entirely to individual institutions.

Lastly, FASEB would like to raise a concern over the inclusion of agent inventories and security issues (Section III-B, for BSL-3/ABSL-3 and BSL-4/ABSL-4 work) in publicly posted incident reports. Together, these postings could reveal which agents are held at which institutions and when controls failed, which may expose institutions and investigators to undue media exposure and reputation harm for what are often routine incidents. It could also lead to additional security concerns and increase security management requirements. FASEB asks NIH to consider whether incidents involving inventory or security issues warrant distinct handling for public posting.

6. Other feedback relevant to this resource: N/A

Description: The attached letter is FASEB’s complete response, expanding on the comments above with additional detail, examples, and recommendations, including on tiered oversight, risk determination for novel and emerging systems, incident reporting, implementation resources, and coordination with the U.S. Government Policy for Stopping High-Risk Life Sciences Research. Thank you for considering these comments.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biosafety Research Compliance

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk

and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.
Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.
Clinical activities and oversight endpoints
Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.
Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.
Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.
Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.
Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of

corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.
Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language. The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.
As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.
Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.
Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.
Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.
NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review
Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.
Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.
Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.
Proposed designated member review procedure
Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.
If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.
Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

3. Continued utility of Risk Groups: Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.
Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.
Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.
Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.
Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.
Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.
Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

6. Other feedback relevant to this resource: Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.
Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.
Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.
Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders,

including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

Uploaded File: Community_Comments_NIH_Biohazards_Policy.docx

Description: Biosafety Administrator's Association Comments

Community Comments on the Draft NIH Biosafety Policy

Recommendations to the National Institutes of Health Office of Science Policy

We support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving

Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Policy source

Draft NIH Biosafety Policy for Research Involving Biohazards, NIH Notice NOT-OD-26-112, released August 19, 2026. Section references throughout refer to this draft.

398. Róża Przanowska

I am responding: On behalf of myself

Name: Róża Przanowska

Name of Organization: Loyola University Chicago

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cancer biology, RNA biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: "The introduction into cells, organisms, or viruses of nucleic acid molecules that can be transcribed or translated" is a s scientifically imprecise and overbroad. definition since such nucleic acid molecules do not stay in cells long-term. Most such molecules, including mRNA, siRNA, and antisense synthetic oligonucleotides (ASOs), are degraded within hours to days and do not persist or replicate in the host. Treating all of them as a biohazard category conflates transient expression with heritable genetic modification or replication-competent agents, which carry very different risks. This reclassification could lead to confusion, misunderstanding, and loss of public trust in routine RNA research, recombinant vaccine technologies, and new therapeutics development, with potentially devastating public health outcomes.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: These comments reflect my own personal opinion and not necessarily that of my employer. I have serious concerns about publishing the names of the IBC members, especially the Local Non-affiliated Member. The potential for their harassment is high. There needs to be a balance between transparency and privacy. I have served on several IACUC's and IBC's over the years. I would no longer server if my name were made public. There is no clear rationale for making public the names of committee members.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: At a minimum, the Local Non-affiliated Members names should be redacted due to the potential for harassment. There needs to be a balance between transparency and privacy.

6. Other feedback relevant to this resource: There needs to be a clear rationale for the need to publicly name IBC members.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The AAMC appreciates the community outreach that NIH has engaged in over the past year as part of the efforts to modernize the NIH Guidelines and strengthen biosafety oversight. We strongly support the development of a biosafety policy which is reflective of the significant progress in science and can effectively address any evolving challenges in conducting work with biohazards and other agents.
In discussions about the draft biosafety policy with AAMC member institutions, we heard often that the academic medical community has had difficulty in providing a comprehensive response to NIH prior to the release of the implementation guidance for the recently issued United States Government Policy for Stopping High-Risk Life Sciences Research. Institutions largely manage their biosafety and potential dangerous gain-of-function (DGOF) projects through overlapping processes and specialized staff. To address these concerns, we recommend that the NIH Office of Science Policy open a public comment opportunity for a minimum of 60 days after the release of the DGOF implementation guidance to allow for further feedback on the biosafety policy, including potential conflicts or additional regulatory burden that would arise in the implementation of the two policies. AAMC remains concerned about the breadth of the DGOF policy, which could dramatically impede the research timeline while an institution reviews all proposed applications for potential DGOF through a new administrative process.

The AAMC urges that as NIH develops the biosafety policy, the agency prioritize harmonization not only with other NIH policies but with other federal research agencies. In particular, many NIH grantees are also conducting research with plant pathogens and are subject to requirements from the U.S. Department of Agriculture (USDA). The NIH and USDA should ensure a coordinated approach to addressing biosafety issues through policies and regulations.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Many institutions already review all research on their campus that falls under the current NIH Guidelines, and some with an even broader scope. However, while many

institutions voluntarily review this research, we do not believe that there is statutory authority for the agency to require that this policy be applied to non-NIH funded research that is conducted at an institution that receives any NIH funding. We urge NIH to limit this policy's application to NIH-funded research to avoid the situation in which this policy has a fundamentally different scope and reach than any similar policy from NIH or other science funding agencies.

Generally, many institutions appreciate that the draft policy is adaptable and reflects the evolving nature of science. However, the broadened scope of the policy combined with a lack of details about its application, adds a substantial amount of low-risk research to the review and oversight process without guidance on which, if any, projects should be exempt from this policy. The policy as currently written could require investigators to register, for example, every plasmid, gene target, and well-characterized cell line, which would be enormously burdensome and divert resources from thorough evaluation of high-risk research. Importantly, this outcome would not align with the NIH's goal of "removing red tape for low-risk research." We propose that the policy identify specific categories of low-risk research or protocol amendments which are not subject to IBC and/or NIH review.

The draft policy is not clear on how delegated review might relieve some of the burden added by the new requirements. We recommend that any oversight required for routine activities, such as the use of low-risk transgenes in cell culture, should be minimal, requiring only that the institution records that this general category of work is occurring and ensures that the appropriate training, facilities, containment, and safety practices are in place.

In conversations with AAMC member institutions, we heard consistent support for the continued use of Risk Group classifications as a baseline for risk assessment, with several comments that the use of these groups is critical and allows for more flexibility based on the research due to its focus on the properties of the agent in question. Biosafety levels were identified as being an important part of a comprehensive risk assessment and determination of the containment levels needed, depending on any changes to the risk level from the specific research being done.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft policy proposes a six-month implementation timeframe, which would be challenging for institutions. The AAMC recommends that NIH adopt a one-year implementation time frame to allow for better integration with institutional timelines, which often require an annual review or progress report, and a longer timeframe to put new institutional guidance documents, manuals, and training, into place. We urge NIH to allow currently approved protocols to be considered compliant for the original duration of the approval, so that ongoing research that newly enters the scope of a revised policy will not be disrupted or paused while waiting for evaluation and approval. Additionally, many institutions have noted that a change to a de novo registration submission for the protocol after three years will cause administrative burden without any added benefit. We would recommend that these be changed to a resubmission, similar to the current process for IACUC protocols.

While additional flexibility for and empowerment of Institutional Biosafety Committees (IBCs) is

appreciated, there are components of the draft policy which should be amended to allow for even more streamlined IBC management and operations. It is helpful for NIH to share the necessary elements of meeting minutes, but institutions noted that issuing a required template increases, rather than decreases, administrative burden. Many IBCs do not run their meetings in the same way, and the lengthy template can create obstacles with the software systems used to support this process. With respect to the proposed requirement to post meeting minutes online prior to the next meeting, we recommend that the requirement instead be "within 30 days of the meeting," as IBCs from different institutions meet at different frequencies. A 30-day time frame for all institutions would allow sufficient time for review and posting.

AAMC agrees with the NIH that transparency is a key component of biosafety research, and further notes that transparency must be balanced with the safety of the individuals conducting and overseeing this research, the security of research facilities, the necessity to maintain confidential information, and the ability to have procedures in place which facilitate open reporting at the institution. Public posting of incident reports may discourage investigators from reporting incidents to the institution and also present safety concerns for these labs and researchers. Given that the focus and primary goal is for the institution to be made aware of these incidents and for NIH to receive this information and take any appropriate action, we recommend that incident reporting continue to be communicated directly to the agency, without a requirement for public posting. If the public posting requirement is retained, we strongly urge NIH to list specific elements of the reports that may reasonably be redacted from publicly-posted records to preserve the security and privacy of scientists, staff, and the laboratories in which they work. Finally, we recommend that the Annual Incident Summary Report from NIH should preserve institutional anonymity, where appropriate, to prevent public identification and potential targeting of any individual institution.

6. Other feedback relevant to this resource: We additionally appreciate the NIH's acknowledgement that "resources and guidance will be required to achieve successful implementation of a modernized biosafety policy." This point was reiterated by all institutions, with the following specific comments on what would be helpful from the agency: NIH should provide further information on expected components for the training for investigators and IBC members; NIH should list the required elements for the IBC registration form and biosafety assurance from an institution; and it would be helpful for NIH to provide additional clarification of the terms "GDMO," "well-characterized cell lines," and "low-risk transgenes."

Re: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Submitted via https://osp.od.nih.gov/comment-form-draft-nih-biosafety-policy-for-research-involving-biohazards/

The AAMC[1] appreciates the community outreach that NIH has engaged in over the past year as part of the efforts to modernize the NIH Guidelines and strengthen biosafety oversight. We strongly support the development of a biosafety policy which is reflective of the significant progress in science and can effectively address any evolving challenges in conducting work with biohazards and other agents.

In discussions about the draft biosafety policy with AAMC member institutions, we heard often that the academic medical community has had difficulty in providing a comprehensive response to NIH prior to the release of the implementation guidance for the recently issued United States Government Policy for Stopping High-Risk Life Sciences Research.[2] Institutions largely manage their biosafety and potential dangerous gain-of-function (DGOF) projects through overlapping processes and specialized staff. To address these concerns, we recommend that the NIH Office of Science Policy open a public comment opportunity for a minimum of 60 days after the release of the DGOF

[1] Established in 1876, the AAMC is a nonprofit association dedicated to improving the health of people everywhere through medical education, clinical care, biomedical research, and community collaborations. Its members are all 163 U.S. medical schools accredited by the Liaison Committee on Medical Education; 12 Canadian medical schools accredited by the Committee on Accreditation of Canadian Medical Schools; more than 400 academic health systems and teaching hospitals; and more than 70 academic societies. The AAMC also collaborates with the Department of Veterans Affairs (VA) and VA medical centers through their academic affiliations with AAMC-member institutions. Through these institutions and organizations, the AAMC leads and serves America's medical schools, academic health systems and teaching hospitals, and the millions of individuals across academic medicine, including more than 220,000 full-time faculty members, 100,000 medical students, 167,000 resident physicians, and 60,000 graduate students and postdoctoral researchers in the biomedical sciences. Through the Alliance of Academic Health Centers International, AAMC membership reaches more than 60 international academic health centers throughout five regional offices across the globe.

[2] USG Policy for Stopping High-Risk Life Sciences Research. https://grants.nih.gov/grants/guide/notice-files/NOT-OD-26-101.html

implementation guidance to allow for further feedback on the biosafety policy, including potential conflicts or additional regulatory burden that would arise in the implementation of the two policies. AAMC remains concerned about the breadth of the DGOF policy, which could dramatically impede the research timeline while an institution reviews all proposed applications for potential DGOF through a new administrative process.

The AAMC urges that as NIH develops the biosafety policy, the agency prioritize harmonization not only with other NIH policies but with other federal research agencies. In particular, many NIH grantees are also conducting research with plant pathogens and are subject to requirements from the U.S. Department of Agriculture (USDA). The NIH and USDA should ensure a coordinated approach to addressing biosafety issues through policies and regulations.

The draft policy proposes a six-month implementation timeframe, which would be challenging for institutions. The AAMC recommends that NIH adopt a one-year implementation time frame to allow for better integration with institutional timelines, which often require an annual review or progress report, and a longer timeframe to put new institutional guidance documents, manuals, and training, into place. We urge NIH to allow currently approved protocols to be considered compliant for the original duration of the approval, so that ongoing research that newly enters the scope of a revised policy will not be disrupted or paused while waiting for evaluation and approval. Additionally, many institutions have noted that a change to a *de novo* registration submission for the protocol after three years will cause administrative burden without any added benefit. We would recommend that these be changed to a resubmission, similar to the current process for IACUC protocols.

While additional flexibility for and empowerment of Institutional Biosafety Committees (IBCs) is appreciated, there are components of the draft policy which should be amended to allow for even more streamlined IBC management and operations. It is helpful for NIH to share the necessary elements of meeting minutes, but institutions noted that issuing a required template increases, rather than decreases, administrative burden. Many IBCs do not run their meetings in the same way, and the lengthy template can create obstacles with the software systems used to support this process. With respect to the proposed requirement to post meeting minutes online prior to the next meeting, we recommend that the requirement instead be "within 30 days of the meeting," as IBCs from different institutions meet at different frequencies. A 30-day time frame for all institutions would allow sufficient time for review and posting.

AAMC agrees with the NIH that transparency is a key component of biosafety research, and further notes that transparency must be balanced with the safety of the individuals conducting and overseeing this research, the security of research facilities, the necessity to maintain confidential information, and the ability to have procedures in place which facilitate open reporting at the institution. Public posting of incident reports may discourage investigators from reporting incidents to the institution and also present safety concerns for these labs and researchers. Given that the focus and primary goal is for the institution to be made aware of these incidents and for NIH to receive this information and take any appropriate action, we recommend that incident reporting continue to be

communicated directly to the agency, without a requirement for public posting. If the public posting requirement is retained, we strongly urge NIH to list specific elements of the reports that may reasonably be redacted from publicly-posted records to preserve the security and privacy of scientists, staff, and the laboratories in which they work. Finally, we recommend that the Annual Incident Summary Report from NIH should preserve institutional anonymity, where appropriate, to prevent public identification and potential targeting of any individual institution.

Many institutions already review all research on their campus that falls under the current NIH Guidelines, and some with an even broader scope. However, while many institutions voluntarily review this research, we do not believe that there is statutory authority for the agency to require that this policy be applied to non-NIH funded research that is conducted at an institution that receives any NIH funding. We urge NIH to limit this policy's application to NIH-funded research to avoid the situation in which this policy has a fundamentally different scope and reach than any similar policy from NIH or other science funding agencies.

Generally, many institutions appreciate that the draft policy is adaptable and reflects the evolving nature of science. However, the broadened scope of the policy combined with a lack of details about its application, adds a substantial amount of low-risk research to the review and oversight process without guidance on which, if any, projects should be exempt from this policy. The policy as currently written could require investigators to register, for example, every plasmid, gene target, and well-characterized cell line, which would be enormously burdensome and divert resources from thorough evaluation of high-risk research. Importantly, this outcome would not align with the NIH's goal of "removing red tape for low-risk research." We propose that the policy identify specific categories of low-risk research or protocol amendments which are not subject to IBC and/or NIH review.

The draft policy is not clear on how delegated review might relieve some of the burden added by the new requirements. We recommend that any oversight required for routine activities, such as the use of low-risk transgenes in cell culture, should be minimal, requiring only that the institution records that this general category of work is occurring and ensures that the appropriate training, facilities, containment, and safety practices are in place.

In conversations with AAMC member institutions, we heard consistent support for the continued use of Risk Group classifications as a baseline for risk assessment, with several comments that the use of these groups is critical and allows for more flexibility based on the research due to its focus on the properties of the agent in question. Biosafety levels were identified as being an important part of a comprehensive risk assessment and determination of the containment levels needed, depending on any changes to the risk level from the specific research being done.

We additionally appreciate the NIH's acknowledgement that "resources and guidance will be required to achieve successful implementation of a modernized biosafety policy." This point was reiterated by all institutions, with the following specific comments on what would be helpful from

the agency: NIH should provide further information on expected components for the training for investigators and IBC members; NIH should list the required elements for the IBC registration form and biosafety assurance from an institution; and it would be helpful for NIH to provide additional clarification of the terms “GDMO,” “well-characterized cell lines,” and “low-risk transgenes.”

Biomedical research involving potential biohazards is critical to our understanding of infectious diseases and emerging health threats, and an essential component of the public health enterprise in the United States. Federal regulations and policies addressing biosafety for this research should ensure it is conducted ethically and with appropriate oversight and training but not impede the ability to do this research, which can be extremely time-sensitive in the event of immediate threats. Any biosafety policy should not impede scientific progress or our ability to anticipate and respond to health and environmental risks in collaboration with the necessary scientific partners.

AAMC is strongly in support of the NIH’s goals to “augment public safety, transparency, and accountability in its stewardship of the biomedical research enterprise” and look forward to NIH’s continued engagement with the research community as it finalizes the biosafety policy. We would be pleased to provide additional information or clarification on any of the recommendations in these comments. For questions, please contact Anu Dev, PhD, Director, Science Policy and Strategy (adev@aamc.org).

Sincerely,

[redacted]
Elena Fuentes-Afflick, MD, MPH

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: a) We support the 4-year timeframe for submittal of a written Biosafety Assurance. However, minimum expectations for attaining NIH approval must be detailed to provide consistency from one institution to another.
b) We support re-registration of IBC protocols after 3 years from initial approval but suggest that the 3-year period be from either initial registration, re-registration, or amendment.
c) We support the emphasis on risk assessments with flow of the process from PI to IBC.
d) The scope of the policy should be clarified with consideration of NIH's mission and titled in a manner that reflects that scope.
e) At times, the policy references risk to human health as a threshold (i.e., section titled "Scope") and other times reference is made to human disease (i.e., definition of biological agent). These are very different concepts which makes it difficult to determine applicability of the policy to plant pathogens, GMO plants, animal pathogens that do not cause disease in humans, GMO animals, etc. For example, an animal pathogen that does not cause disease in humans may pose threat to human health if its uncontrolled spread in agriculture threatens the food supply and/or economic impact.
f) Likewise, the terms "biohazard" and "biological agent" are used inconsistently throughout the policy. The definitions do not contain the term "biohazard." These terms should be defined and used in a deliberate fashion throughout the policy to provide clarity. Furthermore, the definition for biological agent contained in the policy is not consistent with the broadly recognized definition of biological agent within the research community, which will likely lead to confusion and inconsistency in applying the policy. Consideration should be given to using the term "hazardous biological agent" or some uniquely coined term and defining such.
g) The Scope of the policy references "potential risk to human health" but gives no threshold for potential risk. The threshold should be clarified. Is it a substantial potential, reasonable potential, any potential? We encourage adoption of the following threshold: "an assessment of an outcome such that, generally, individuals with scientific expertise relevant to the research in question would expect this outcome to occur but exclude experiments in which experts would anticipate the outcome to be technically possible, but highly unlikely."
h) We encourage consideration of a threshold for toxins for inclusion within the scope of the policy,

which could be based on level of toxicity such as LD50 and aggregate amount on hand or in process at any given time.
i) Within the definition of Genetic Modification, we encourage limiting the second bullet to the germ line of multi-cellular organisms to avoid overly broad application of the policy. Of particular concern is inclusion of chemical or radiological means and the absence of discussion or limitiation of genetic alterations that result in biological hazards and resultant risks.
j) The current NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules provide greater clarity on containment requirements as it relates to genetically modified organisms. The draft policy does not address setting of appropriate containment levels for research involving genetically modified organisms, particularly when genetic material from a higher risk group organism is transferred to a non-pathogenic or lower risk group organism. Related provisions in Section III-D of the existing Guidelines should be incorporated into the new policy. Furthermore, the draft policy should be modified to explicitly address setting containment levels for biological agents that are not human pathogens, assuming such is within the scope of the policy, and the need or lack thereof for petitioning the NIH to set the containment level. It should also be clarified that Risk Group is one consideration in selecting the final containment level and, while complementary, risk group and containment level are not synonymous or interchangeable.
k) We encourage that the policy specifically exempt those experiments currently described in Section III-F of the current NIH Guidelines.
l) We encourage that the policy specifically include those experiments currently described in Section III-E of the current NIH Guidelines into Section IV-3 of the proposed policy. Furthermore, the term “minor amendment” in Section IV-3 of the draft policy should be defined.
m) The draft policy represents a significant departure from the current NIH Guidelines and greatly expands the scope and reach of the policy. Compliance with the draft policy will require a complete rebuilding of institutional programs, policies, training, oversight, and review of research proposals, as well as analysis and review of existing research. A six-month implementation deadline will not be feasible for most research institutions. We encourage extending the effective date for a minimum of 18 months, with the caveat that institutions continue to comply with the existing NIH Guidelines and applicable Executive Orders until they have established policies and procedures consistent with the revised policy. Furthermore, allowance for a graduated approach is needed to prevent everything from being due at the same time, which would also extend to future protocol re-submissions, Biosafety Assurances, and other requirements in the policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: We support recognition of the BMBL when setting containment levels and encourage expansion to recognize containment levels set by other federal agencies as a permit condition (such as USDA APHIS and CDC VS permits). However, the NIH must clearly distinguish portions of the BMBL that are considered mandatory and those that are considerations when selecting alternatives for specific research applications. Further, we encourage allowing institutions to set containment for biological agents that present low risk based on literature review rather than requiring petitioning of the NIH to set containmnet.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: a) We oppose the requirement to publicly post incident reports when such reports are available under the Freedom of Information Act or equivalent state legislation. Such a requirement, particularly when it does not involve a significant threat to human health or the environment, will unnecessarily deter reporting. Further, we do not support inclusion of the name of the Principal Investigator or grant identifying information in the incident report.
b) We also ask for clarification of the requirement to post IBC meeting minutes (and incident reports if that requirement remains) "on a pubic-facing webpage on the website of the institution (p.5, bullet 2, under the heading of "IBC Functions)." We encourage this to not mean the main landing page of an institution, but rather a sub-website where all other IBC information is posted and which is readily accessible to the general public.

6. Other feedback relevant to this resource: a) Does the definition of laboratory research and the statement in Section II (research conducted within BSL.ABSL 1-4 containment spaces…) apply to the research project or the facility where the project is conducted?
b) We are concerned with lack of details regarding "BSL3 enhanced containment for HPAI H5N1 work" (Section V-E). Specifically, what is meant by "enhancement"? We think a definition of enhancement must be included in this document.
c) NIH should clarify how institutions are expected to integrate risk assessments, mitigation measures, oversight conditions and reporting obligations when the same research activity is subject to both the NIH Policy for Research Involving Biohazards and the USG Policy for Stopping High-Risk Life Sciences Research.
d) The definitions contain separate definitions for "biomedical research" and "laboratory research" yet the term "laboratory research" does not appear in the policy other than as a definition.
e) Section III-B (Responsibilities of the Institutional Biosafety Committee), Subsection Titled "IBC Functions", first bullet, states that the IBC is responsible for …. (1) independent risk assessment of the biocontainment levels required for the proposed research…. We suggest that this statement be modified to indicate that the IBC is responsible to review and approve or request changes to the Principal Investigator's initial risk assessment rather than mandating an independent risk assessment.
f) Section III-B (Responsibilities of the Institutional Biosafety Committee), Subsection Titled "IBC Functions", bullet 10 requires reporting of "certain incidents to the NIH that pose significant risk to human health" within 24 hours and goes on to state that these reporting requirements include incidents that involve a number of situations (such as Laboratory Acquired Infection, loss of containment, etc.). However, the last bullet of this list is "any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approval, or failure to obtain NIH approval for lowering biocontainment research, when required." This last bullet does not necessarily rise to the threshold of "pose significant risk to human health" and should be a separate reporting requirement with a greater reporting period, as currently required under the existing NIH Guidelines.
g) Implementation guidance in all areas is critical to the effective implementation of the proposed policy. We encourage guidance similar in nature to that which was provided for the former DURC/PEPP USG policy.

402. Stephanie Adams

I am responding: On behalf of myself

Name: Stephanie Adams

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Role - Other: Biosafety Professional - Why is there NO Role entry for this!!!!! It just shows.

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: In "Section IV-3. "
The individual must be an Biosafety professional, who can review and approve all amendments for minor changes or if the registration is for the use of :
Research involving RG2 wild type biological agents.
Research with genetically modified RG1 biological agents [Note: Experiments involving RG1 wild-type biological agents are not subject to this Policy].
Research conducted with transgenic organisms at BSL-1/ABSL-1.
Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes.
Research with well-characterized cell lines.
Research with biological toxin proteins not on the Select Agent list.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The Draft Policy also places significant responsibilities on biosafety officers (BSOs), Institutional Biosafety Committees (IBCs), and institutions, but it fails 2 Comments on NIH Biosafety Policy to empower them to carry out these responsiblities with sufficient independence and authority, along the lines that institutional review boards (IRBs) and institutional animal care and use committees (IACUCs) do under their governing regulations.

Biosafety officer and IBC committee must be given resources and funding to actually be able to do the work.

Not everyone is qualified to serve as a Biosafety Officer. At a minimum, a Biosafety Officer should have at least two years of laboratory or clinical experience and three years of dedicated biosafety experience.

Every IBC committee must have at least 2 Biosafety Officers on their committee to ensure correct mitigation practices that also align with the whole institution.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: We cannot name anyone on the incident reporting. This can become a HIPAA violation.

6. Other feedback relevant to this resource: N/A

National Institutes of Health
Office of Science Policy
Attn: Cari Young, Sc.M., Director of Biosafety, Biosecurity, and Emerging Bioteechology Policy Division

RE: Response to Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards

To Whom It May Concern:

The Association of American Universities (AAU), Association of Public and Land-grant Universities (APLU), and COGR write to offer comments in response to the Draft NIH Biosafety Policy for Research Involving Biohazards (Draft Policy) published in the Federal Register on September 14, 2026. [91 FR 58132].

Founded in 1900, AAU comprises 69 of America's leading research universities that transform lives through education, research, and innovation. Research universities, including AAU members, have a long-standing partnership with the federal government to advance science and technology in the national interest. This partnership, rooted in World War II, has been central to U.S. global leadership in science and technology.

APLU is a membership organization that advances the mission of land-grant and public research universities. Founded in 1887, APLU is the oldest higher education association in the United States. Its U.S. membership consists of more than 240 land-grant and public research universities, state university systems, and affiliated organizations spanning across all 50 states, the District of Columbia, and five U.S. territories. The association and its members

collectively focus on increasing student success and workforce readiness; promoting pathbreaking scientific research; and bolstering economic and community engagement. Annually, its U.S. member campuses enroll 4.6 million undergraduates and 1.4 million graduate students, award 1.3 million degrees, employ 1.3 million faculty and staff, and conduct $70 billion in university-based research.

COGR is the national authority on federal policies and regulations affecting U.S. research institutions. We provide a unified voice for over 230 research universities and affiliated academic medical centers and research institutes. Our work strengthens the research partnership between the federal government and research institutions and furthers the frontiers of science, technology, and knowledge. We advocate for effective and efficient research policies and regulations that maximize and safeguard research investments and minimize administrative and cost burdens.

The academic research institutions that AAU, APLU, and COGR represent understand and support NIH's desire to update its current Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules ("NIH Guidelines") beyond the changes that were incorporated into those Guidelines in April 2024. Our member institutions are leaders in the conduct of biomedical research and fully support risk-based policies that protect researchers and the public from biohazards, while facilitating conduct of the broad spectrum of life sciences research necessary to ensure America's ability to understand and address threats to individual and public health. They also support regulations that embue biosafety officers (BSOs) and institutional biosafety committees (IBCs) with the power and authority to provide oversight for research involving biohazards.

Unfortunately, the Draft Policy does not callibrate required controls to actual risk presented, particularly in the case of lower-risk research activities. During the stakeholder consultation process, we were encouraged by discussions regarding how the Draft Policy could take a more risk-based approach to regulation. However, the Draft Policy does not retain many of the risk-based features of the NIH Guidelines. Instead, it adopts an overly risk-averse approach that substantially increases institutions' review and oversight responsibilities for low-risk research that was previously exempt.

The Draft Policy also places significant responsibilities on biosafety officers (BSOs), Institutional Biosafety Committees (IBCs), and institutions, but it fails

to empower them to carry out these responsiblities with sufficient independence and authority, along the lines that institutional review boards (IRBs) and institutional animal care and use committees (IACUCs) do under their governing regulations. Instead, the Draft Policy's vast scope (which includes virtually ALL research involving biological agents conducted at any institution that receives NIH funding), coupled with its overly prescriptive and risk averse requirements for IBC review, oversight and reporting functions, will substantially increase administrative burden while diverting limited biosafety resources from higher-risk activities, potentially undermining, rather than increasing, laboratory and public safety. Further, despite requiring institutions to provide review and oversight for non-NIH/non-federally funded research, the Draft Policy provides neither statutory support for these requirements nor mechanisms to reimburse institutions for associated implementation costs. Accordingly, as an overarching comment, we urge NIH to reevaluate both the scope of the Draft Policy and its risk calibration.

Below, are additional general comments regarding the Draft Policy, followed by comments and recommendations on specific policy provisions. In addition, our organizations recommend NIH consider using a notice of proposed rulemaking that includes the statutory basis for the proposed changes and a regulatory-impact analysis to facilitate such an extensive policy change.

GENERAL COMMENTS

▪**Intersection between Draft Policy and United States Government Policy for Stopping High Risk Life Sciences Research ("USG Policy"):** Given the Draft Policy's coverage of "research involving biohazards" and the USG Policy's coverage of broadly defined "Potential Dangerous Gain of Function (DGOF) Research" and "Other Risky International Research," there is substantial potential for overlap between the two policies. Unfortunately, the USG Policy had not been issued at the time that NIH was collecting stakeholder input on the Draft Policy. Further, NIH has not yet issued its implementation guidance for the USG Policy. Thus, institutions do not have any information on how NIH anticipates the Draft Policy will intersect with the USG Policy. Accordingly, it seems premature to collect stakeholder input on the Draft Policy, until NIH is in a position to provide these details.
Recommendation: Our associations urge NIH to extend the final date of the comment period on the Draft Policy to a date that falls at least 60 days after NIH has released its implementation guidance for the USG Policy and provides information on how the two policies intersect.

▪**Scope of Draft Policy Exceeds Statutory Authority:** NIH cites no statutory authority to support extending the scope of the Draft Policy to "non-funded NIH research that is conducted . . . at an institution that receives any NIH funding" ("Funded Institution"). Indeed, the only reference to biological agents and toxins contained in the statute prescribing the NIH director's duties/authorities is a requirement for the director to consult with named federal agencies/offices, "as appropriate, ***regarding research needs*** to advance medical countermeasures to diagnose, mitigate, prevent, or treat harm from any biological agent or toxin, including emerging infectious diseases, chemical, radiological, or nuclear agents that may cause a public health emergency or other research needs related to emerging public health threats." [42 USC §282(b)(26) (***emphasis added***)].
Recommendation: NIH should provide the explicit statutory authority that authorizes it to include within the Draft Policy's scope non-federally funded research conducted at a Funded Institution, or, in the absence of such explicit authority, confine the Draft Policy's scope to NIH-funded research. Further, as noted, given the scope and magnitude of the Draft Policy, NIH should consider issuing the Draft Policy through the federal notice and comment rulemaking process, as opposed to issuing it as an agency policy.

▪**Draft Policy is Not Accurately Risk Calibrated and Places Substantial and Unjustified Administrative and Cost Burdens on Institutions:** Although the Draft Policy claims to support a risk-based approach to the review and oversight of biomedical research, its approach is not accurately risk calibrated. Specifically, the Draft Policy is overly risk-averse because it vastly increases the scope of research requiring IBC and/or NIH review by eliminating categories of low-risk research that were previously exempt from IBC review processes. Further, the Draft Policy's provisions concerning inspections, continuing reviews, and other oversight activities also lack risk calibration and/or are duplicative of oversight efforts in place via other regulatory and institutional mechanisms (e.g., IACUC semi-annual inspections, institutional lab safety inspections).

NIH's failure to "right-size" the draft Policy to the level of risk presented by specific activities results in unnecessary oversight for lower-risk activities, which in turn diverts resources that could be more effectively devoted to managing higher risk research. Further, NIH expects Funded Institutions to perform these responsibilites for ALL non-NIH funded research within the policy's scope. Yet, the policy contains no mechanism to ensure that institutions are fully reimbursed for costs associated with providing these

oversight functions. The Draft Policy also fails to adequately account for the security, privacy, and confidentiality risks created by the mandated public posting of information regarding biosafety procedures, IBC meeting minutes, the conduct of BSL/ABSL-3 or BSL/ABSL-4 research, and incident reports.

Recommendation:

(a) Develop and include within the Draft Policy categories of lower-risk research activities that do not require IBC and/or NIH review.

(b) As previously noted, remove non-NIH funded activities from the Draft Policy's scope. Alternatively, if NIH can demonstate appropriate statutory authority to support its regulation of these actitivies, it should specify within the Draft Policy how institutions will be compensated via NIH funding mechanisms for providing the oversight functions NIH is mandating.

(c) Modify the Draft Policy to permit IBCs to calibrate the type and frequency of oversight activities to actual risks presented by research activities and to coordinate with and prevent duplication of other inspection/review efforts carried out within the institution.

(d) Develop and include with the Draft Policy more detailed research security and privacy factors that institutions can rely upon to support the redaction of confidential and/or senstive private information from minutes and incident reports prior to posting, or alternatively, require only anonymized aggregated reporting.

▪**Draft Policy Uses BMBL in More than an Advisory Capacity:** The foreword to the CDC's Biosafety in Microbiological and Biomedical Laboratories (BMBL) explicitly states that it is an "advisory document," and it is not intended to be a "regulatory document." Rather, the BMBL was intended to be a periodically updated guidance document designed to support expert risk assessment and preserve institutional discretion. Despite this caution, the Draft Policy uses the containment levels set forth in the BMBL in a regulatory manner and constricts the IBC's ability to lower containment levels without NIH approval. The fact that the current issue of the BMBL was last revised prior to the COVID pandemic reveals a major flaw in using the BMBL in such a regulatory manner, i.e., the information in the BMBL is not continuously updated to reflect the latest scientific developments.

Recommendation: NIH should clearly state in the Draft Policy that the BMBL remains an advisory document, and as such, the establishment of containment levels by IBCs and NIH will be governed by current scientific evidence and may be higher *or lower* than BMBL-suggested levels when scientifically justified. Our organizations also urge NIH to ensure that there are adequate funding and operational mechanisms in place to continuously

update the BMBL to make certain that the information it contains accurately reflects the current state of scientific knowledge.

▪**Implementation Timeline is Too Short:** The Draft Policy specifies that it will take effect six months from the date of publication of the final policy with respect to new and existing NIH-funded research and non-NIH funded research conducted at an institution that receives NIH funding. The substantial increase in the portfolio of research that must be reviewed under the Draft Policy will place tremendous strain on institutions' existing IBC and biosafety operations and more than six months will be needed to take stock of new categories of research that require review; update institutional policies, processes, procedures, workflows, and associated tools; and train researchers and staff on the new policies/procedures.
Recommendation: Our organizations urge NIH to extend the effective date to 24 months from the date on which the final policy is published to afford institutions adequate implementation time. At a minimum, NIH should extend the effective date by at least 12 months from the final policy's publication date.

▪**Draft Policy is Unclear as to How Genetically Modified Plants will be Addressed:** Unlike the current policy, the Draft Policy does not include genetically modified plants within its framework, elminating a long-standing source of containment guidance for institutions, as well as best practices for greenhouse research, growth chamber research, pollen containment, reproductive isolation, and prevention of environmental release.
Recommendation: NIH should clarify how the government plans to handle guidance regarding genetically modified plants, including whether, NIH or another federal agency, plans on issuing guidance on this topic.

▪**Policy Format is Difficult to Follow:** The Draft Policy's lack of sequentially numbered sections and subsections make it difficult to use and cite.
Recommendation: To improve user friendliness, NIH should sequentially number each section and subsection of the Draft Policy.

SPECIFIC COMMENTS

Section I, Purpose: No comments.

Section II, Scope: See comments below.

▪**Draft Policy's Scope Is Overly Broad and Not Risk-Based:** The Draft Policy applies to "reseach involving known or potential risk to human health" and any of the items listed in provisions 1-4 of the Scope Section, including "[c]ells or organisms, other than plants," containing any of the items listed in items 1-3 of the Scope Section. However, virtually all organisms/cells contain some level of microorganismal contaminination. Further, there is no universal screening process for human pathogens, and some bacteria/microorganisms pose risk to only limited segments of the population (e.g., immunocrompomised individuals). Thus, as written, the Draft Policy **essentially treats every biological agent as a biohazard**, and by doing so it applies **to virtually any organism, with the exception of plants, without regard to actual risks presented. This approach serves to divert institutional/IBC time and resources to the assessment and review of lower-risk biomedical research and unnecessarily impedes the conduct of such research.**
Recommendation: To truly make the Draft Policy risk-based, we urge NIH to limit its scope to cells or organisms, other than plants, that contain one of the items in provisions 1-3, and that are known, or likely to cause, disease in humans. For example, certain toxins and self-aggregating proteins may not pose risk to human health in the absence of LD50 thresholds and/or clear evidence of causation of disease/harm. We also urge NIH to establish categories of lower-risk research such as research conducted at BSL-1/ABSL-1 that are excluded from the scope of the policy and/or are exempt from IBC or NIH review.

▪**Items within the Scope Section that Require Clarification:** The following provisions within the scope section are confusing and would benefit from additional clarification:

- **Laboratory Settings:** The term "laboratory settings" should be defined and distinguished from the defined term "laboratory research." Specifically, the Scope section states that the Draft Policy covers "all biomedical research, in ***laboratory settings,*** involving biohazards," [***emphasis added***] but the terms "laboratory settings" and "biohazards" are not defined. Instead, the Draft Policy defines the term :"Laboratory Research" as research conducted in BSL/ABSL 1-4 containment facilities. Accordingly, the scope of the policy is unclear. For example, are arthropod containment facilities, insectaries, or greenhouses considered to be "laboratory settings"? Does the Draft Policy apply to field research?
- **Clinical Research:** It is also unclear how the Draft Policy applies to clinical research, which is traditionally subject to other oversight mechanisms (e.g., OSHA bloodborne pathogen standard, hospital

infection control committee requirements). As previously noted, the policy defines Laboratory Research in terms of research conducted at BSL/ABSL levels in containment facilities but goes on to note that clinical research does not utilize traditional biosafety levels. Indeed, the only guidance the Draft Policy provides regarding risk assessment/mitigation in clinical settings is that "precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection."

Recommendation: NIH should clarify when and how the Draft Policy applies to research conducted in clinical settings. Additionally, our organizations recommend that risk assessment/mitigation in clinical setting utilize universal precautions as a baseline, coupled with additional controls (e.g., transmission precautions) based on hazard characteristics and routes of transmission associated with the items being studied. Along these same lines, NIH should clarify IBC review requirements for clinical research under Section IV.2, and detail how they intersect with other requirements in clinical settings (e.g., OSHA bloodborne pathogen requirements, hospital infectious control requirements, etc.).

- ***In Silico* Research:** The Draft Policy is unclear as to whether *in silico* research on items listed under provisions 1-4 of the Scope Section falls under the policy's auspices.

Recommendation: NIH should clarify whether *in silico* research on items listed under provisions 1-4 of the Scope Section does/does not fall within the scope of the Draft Policy, because such research does not necessarily involve a known or potential risk to human health.

- **Applicabilty to Lower-Risk Research Activities:** The draft policy is limited to "research involving known or potential risk to human health." This limitation suggests that the Draft Policy should not apply to certain lower-risk reseach (e.g., RG1 recombinant materials, gene drive modified organisms (GDMOs), and transgeneic animals at BSL-1/ABSL-1). However, several sections of the Draft Policy appear to require institutional registration and review of these lower-risk research activities without sufficient explanation and support for such risk calibration.

Recommendation: Given that NIH intends for the Draft Policy to be risk-based, NIH should specify those categories of lower-risk research activities that are excluded from the policy's scope. If all biomedical research involving the use of biological agents is included within the

Draft Policy's scope, then institutions will be required to devote a huge amount of time and resources to reviewing and providing oversight for low-risk research activities, in exchange for limited benefit in terms of improved safety.

°Examples of Activites Included/Excluded from the DRAFT POLICY: The Draft Policy does not include examples of research that do/do not fall within the policy's scope.
Recommendation: It would be very helpful to institutions if NIH provided concrete examples of research that is (a) within the Draft Policy's scope; and (b) excluded from the Draft Policy's scope. It would also be helpful to institutions if NIH clarified whether/how the Draft Policy applies to animal pathogens and other zoonotic risks, agricultural pathogens, plant pathogens, phages, environmental organisms, prions, and other self-aggregating proteins.

°Research Regulated by Other Federal Agencies: The Draft Policy states: "Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained."
Recommendation: It would be very helpful to institutions if NIH could provide details on how this approval/clearance process will work, including:

- Specifying which federal agencies will have authority over various types of pathogens (e.g., Will USDA have jurisdiction over plant pathogens and genetically modified plants?) and what process institutions will need to follow to determine who has jurisdiction.
- Specifying which agency will have ultimate oversight of biomedical research in areas where multiple agencies (e.g., CDC, OSHA, USDA) have overlapping oversight responsibilities, and how that determination will be made.
- Clarifying the meaning of the phrase "approvals or other applicable clearances" and from which agency (i.e., NIH or another federal agency) institutions are expected to obtain these approvals/clearances.

Section II, Compliance and Enforcement: No comments.

Section II, Voluntary Compliance: No comments.

Section II, General Definitions Section

▪**Overarching Comments:** Several key definitions are overly broad, thus creating uncertainty regarding the Draft Policy's scope and undercutting NIH's stated goal of a risk-based biosafety policy. Additionally, the Draft Policy redefines terms that have well-established scientific meaning, reducing the clarity and consistency needed for effective policy implementation.
Recommendation: NIH should ensure that terms are defined in line with their common usage, and revise overly broad definitions to directly align oversight requirements with actual risks presented. Comments regarding specific definitions follow.

▪**Comments on Specific Definitions:**
°**Biological Agent:** As previously noted, the Draft Policy appears to assume that every biological agent constitutes a biohazard, and definitions clarifying the boundaries between these two terms should be provided. Additionally, the term "parasite," as used in this definition, would benefit from further clarification. For example, parasites could encompass mosquitos, ticks, lice, various helminths, etc., so if the definition is referring to intracellular parasites, it should state so. Similarly, the definition should address whether it encompasses ectoparasites that serve as vectors of disease transmission, as opposed to causing disease. Finally, the definition should also be clear as to how "opportunistic pathogens" that only affect very specific segments of the population should be addressed.
Recommendation: Revise this definition to address the points outlined above.

°**Biomedical Research:** In addition to being extremely broad, this definition has the potential to introduce instability and inconsistency, as it refers to "research on a topic that is within the mission of the NIH," and thus could change dramatically over short periods of time, depending on how Congress and the Executive Branch expand or curtail NIH's mission.
Recommendation: NIH should employ a static definition of biomedical research (e.g., "Research that is conducted to increase fundamental knowledge and understanding of the physical, chemical, and functional mechanisms of human life processes and diseases"[1]) that is not tied to, and does not change with, the scope of NIH's mission.

°**Emerging Agent:** NIH's definition of this term is at odds with the definition

[1] Definition of "biomedical research," NIH, Collection Development Guidelines of the National Library of Medicine (2019; updated Sept. 25, 2025).

used by scientists, biosafety, and public health professionals, who consider an "emerging agent" to be a known agent that is emerging as a cause of disease. Further, the NIH definition inappropriately equates a newly identified organism with a pathogen.

Recommendation: NIH should replace this definition with the more commonly accepted definition outlined above. If NIH retains the current definition, it should explicitly define what "newly identified in nature" means. For example, is "newly identified" limited to a new species or genus? Additional points that should be clarified in the definition include the following:

- How would chimeras and plasmids/viral vectors/replicon systems containing genetic material from different sources be viewed?
- How are prions and self-aggregating proteins viewed?
- Does the definition encompass synucleins and preformed fibrils, or other organisms/materials on which there is not yet consensus on whether they cause human disease or are just associated with such disease?

°Genetic Modification: The proposed definition of genetic modification significantly broadens the scope of items covered by the Draft Policy. Specifically, expanding the definition of "genetic modification" to include nucleic acids that can be translated, as well as the alteration of the genome using chemical or radiological means, is inconsistent with the NIH Guidelines' historical approach to oversight of research that introduces stable genetic modifications. Genetically modified organisms **do not** inherently present greater uncertainty. In fact, many genetically modified organisms are well characterized and **present less uncertainty** than their wild-type counterparts. Indeed, the level of uncertainty associated with an organism depends on multiple factors, including the nature of the modification, the amount and quality of available data, the resulting phenotype, and prior experience with the organism. Additionally, the Draft Policy's overly prescriptive approach to genetic modifications will result in inconsistent and duplicative oversight (e.g., overlap with FDA and existing laboratory oversight requirements) and adds little to no value in terms of improved biosafety. Rather, this approach has the potential to increase risk by causing the IBC and biosafety team to "spread themselves thin" by expending time and resources on lower-risk activities, instead of focusing on research presenting higher risks.

Recommendation: NIH's new approach to viewing all genetic modifications as suspect is inconsistent with NIH's intent to develop a risk-based policy. NIH should instead incorporate into the definition of genetic modifications a provision that limits IBC review and oversight to only those genetic

modifications that present specific risk characteristics and/or consequences based on available evidence.

°**Laboratory Research:** The Draft Policy includes the terms "laboratory settings" and "laboratory research," but only provides a definition for "laboratory research," which it defines in terms of containment levels.
Recommendation: As previously noted, NIH should include a definition of "laboratory settings," a term used in the Scope Section. Our organizations also recommend that NIH clarify whether the scope of the policy is based on "laboratory settings" or 'laboratory research." Finally, given that not all "laboratory research" requires containment levels, NIH should consider renaming this term as "laboratory research requiring containment" to avoid causing confusion among scientists and biosafety personnel who commonly understand this term as any research taking place in a lab setting.

°**Research Involving Biohazards:** This term is defined in the scope section, but it does not appear in the general definitions section.
Recommendation: For consistency, NIH should include "research involving biohazards" as a defined term within the general definitions section and specify how the term relates to the setting in which such research is performed, i.e., laboratory settings.

°**Toxins:** The Draft Policy defines a "toxin" as: "[a] protein or peptide produced by living organisms that causes harm in humans." Many biological molecules may cause harm under certain exposure conditions or at sufficiently high concentrations, but absent such conditions, they may be harmless. Although the risk assessment section of the Draft Policy appropriately accounts for factors such as potency, amount used, and intracellular accessibility, these concepts are absent from the definition. Additionally, the definition does not address the potential of exceptions for naturally occurring toxins (e.g., those produced by algae, use of cephalopods, etc.).
Recommendation: NIH should incorporate objective criteria (e.g., potency, exposure potential, quantity, biological activity) into the definition of "toxin," and consider using LD50 levels as a criterion for inclusion under the Draft Policy.

Section III, Roles and Responsibilities: See comments below.

Section III-A, Responsibilities of the Institution

▪**Applicability:** As previously noted, extending the Draft Policy to non-federally funded research conducted at institutions that receive any NIH funding appears to exceed the scope of NIH's regulatory authority.
Recommendation: NIH should identify the specific statutory authority supporting the extension of the Draft Policy to non-federally funded research conducted at institutions receiving NIH funding, and absent such specific authority, limit the scope of the Draft Policy to NIH-funded research. NIH should also provide greater clarity in this section and/or in the scope section regarding exactly what entities the policy applies to (e.g., affiliated hospitals, separately incorporated research institutes, subcontractors, international sites).

▪**Biosafety Assurance:** It is imperative that Authorized Organizational Representatives (AORs) specifically understand the criteria to which they are certifying through their execution of the Biosafety Assurance. It is also important that NIH conduct the assurance process in an efficient and streamlined manner that permits institutions to begin/continue covered research without undue delay.
Recommendation: NIH should clarify the following issues in the Draft Policy:

- Is the AOR certifying that the institution has established an adequate biosafety oversight program, or certifying compliance for every individual research activity and researcher covered by the policy?
- Describe the criteria NIH will use to approve, restrict, suspend, or withdraw an Assurance.
- Provide an anticipated turn-around time for NIH' approval of an assurance.

NIH should consider patterning the Biosafety Assurance process after the assurance processes in place at the HHS Office of Human Research Protections or at the Office of Research Integrity. Additionally, it would be helpful to institutions if NIH were to provide a draft template assurance document on which institutions can submit comments.

▪**IBC Training Responsibilities:** The Draft Policy states that an institution is responsible for ensuring appropriate training regarding laboratory safety and implementation for the IBC Chair and members, biological safety officer and other containment experts, principal investigators, and laboratory staff.
Recommendation: NIH should develop and provide role-based training resources that IBCs may use to satisfy these training responsibilities.

▪**Record-keeping requirements:** The Draft Policy vastly expands the scope of research requiring IBC review/oversight, resulting in a tremendous increase in IBC-associated records (both paper and electronic) that must be developed and retained, at substantial storage and archival costs.
Recommendation: NIH should consider implementing a more limited period of record retention. Given that the Draft Policy calls for the IBC to provide *de novo* review of each research protocol every three years, our organizations suggest that NIH cap the record retention period at two review cycles (six years), thus affording transparency, while reducing administrative burden.

▪**Public Posting of IBC Related Documentation:** The Draft Policy calls for the institution to publicly post "to the maximum extent possible" the following documents/information:

- Weblinks to publicly posted institutional biosafety procedures (including but not limited to documentation detailing the IBC roles, responsibilities, authorities, and processes for how biosafety risks are managed);
- A continuously updated IBC roster;
- IBC meeting minutes;
- Incident reports;
- Synopses of relevant staff trainings provided;
- Contact information for the IBC Contact, IBC Chair, and BSO (if applicable); and
- Information regarding whether the institution conducts research in a BSL3/ABSL-3 or BSL4/ABSL-4 laboratory, research with GDMOs, has a BSO, receives NIH funding, and/or has an externally administered IBC.

This approach fails to strike an appropriate balance between the need for public transparency and the need to protect the security of laboratory facilities, the security and privacy of biosafety personnel, and proprietary and confidential information associated with non-federally funded research that now falls within the scope of the Draft Policy.
Recommendation: Our member institutions understand the need for required documentation retention for agency inspection as appropriate under the Draft Policy. Nonetheless, the need for public transparency must be balanced against the goals and requirements of privacy laws (e.g., HIPAA, state privacy laws, collective bargaining agreements) and other policy concerns (e.g., protection of trade secrets, promoting a just and fair culture of incident reporting). With respect to incident reports, which often contain sensitive personal information, NIH should permit anonymized, aggregated reporting with identifiable information disclosed to appropriate governmental officials

only when there is a legitimate need to know (e.g., public health investigation). If NIH declines to adopt anonymized/aggregated reporting, it should not require the posting of any personally identifiable information except for the names and institutional information for the IBC Contact, IBC Chair and BSO.

NIH should also specify within the Draft Policy a de-identification standard (e.g., HIPAA standard) and specify what information can be redacted from records prior to public posting to protect the security and privacy of biosafety personnel and facilities and to safeguard proprietary and confidential information associated with non-federally funded research. Further, NIH should also exempt from posting any information related to processes and procedures developed to ensure the security of covered research and the facilities in which that research is conducted. Finally, the Draft Policy should be exempt from posting any information designated as confidential or proprietary by non-federal research sponsors.

Section III-B, Responsibilities of the Institutional Biosafety Committee

▪**Overarching Concerns:** Although NIH has expressed its intent to elevate and strengthen the role of the IBC and the BSO, the Draft Policy does not clearly delegate to those parties the specific authorities necessary to carry out those responsibilities.
Recommendation: NIH should clearly delineate within the Draft Policy specific authorities of the IBC and BSO (e.g., ability to take timely action to address significant biosafety concerns, suspend research protocols, etc.). NIH should also include provisions within the Draft Policy that ensure the IBC's independent decision-making authority akin to the independent authority of IRBs and IACUCs (e.g., institution cannot reverse IBC's non-approval or suspension of a protocol).

▪**IBC Membership**: No comments.

▪**IBC Functions:** See comments below.

▪**First Sentence of Section ("The IBC, or its delegate as applicable, is responsible for"):** The first sentence's reference to "[t]he IBC, or its delegate as applicable" is confusing.
Recommendation: NIH should clarify whether the term "or its delegate" refers to an individual or subgroup of IBC members assigned to conduct "delegated reviews" under Section IV-3.

- **First Bullet Point:**
  - **Clause (3)("in cases of research involving. . . "):** The concerns noted in clause (3) relating to research involving "human subject research participants" are also applicable to animal research.
    Recommendation: Delete the text that reads "in cases of research involving human research participants."

  - **Third Sentence ("IBC oversight may conclude . . . "):** Shedding may continue after the last dose of a product is administered to human research participants, so it is unclear as to why IBC oversight should end at that point.
    Recommendation: Delete the third sentence ("IBC oversight may conclude after the last participant is administered the final dose of product") and modify the fourth sentence to read as follows: "IBCs should establish appropriate endpoints for oversight based on their biosafety assessment of the proposed research."

  - **First Sub-Bullet Point ("No member of the IBC . . . "):**: It is unclear as to who has the responsibility for determining whether an IBC member has a conflict of interest.
    Recommendation: NIH should include a statement that the IBC is empowered to establish its own processes and procedures for soliciting information from members regarding possible conflicts of interest and determining when such conflicts exist and require member recusal.

- **Second Bullet Point ("Taking IBC meeting minutes. . . "):** Requiring approval of IBC minutes "no later than [the IBC's] next convened meeting," places excess administrative burden on IBCs that meet frequently and review large numbers of protocols. Indeed, one COGR member institution has estimated based on current meeting-minute preparation time and the template content that it will be required to hire a full-time employee just to fulfill the Draft Policy's IBC meeting minutes requirements.
  Recommendation: NIH should extend the period for approval of IBC meeting minutes to "no later than ninety (90) days after the meeting at which the minutes were taken."

- **Third Bullet Point ("Notifying the PI when . . . "):** The Draft Policy calls for "de novo registration submission and review" at least every three years, however, NIH does not provide any rationale for requiring de novo review for all protocols or for selecting a three-year period, as opposed to four or five-year

period. If the Draft Policy is intended to be risk-based, then the period for review and re-registration should be based on risk posed by the research in question, as determined by the IBC.
Recommendation: NIH should modify the Draft Policy to permit the IBC to establish the re-registration period based on the risk posed by a specific research protocol. NIH should also empower the IBC to provide a re-review/re-registration grace period of up to 90 days to accommodate circumstances in which the IBC cannot complete its review within the specified period.

Alternatively, if NIH maintains the strict three-year re-registration/re-review period, it should specify within the policy what the status of a protocol is that (a) has not been reviewed/approved within the three-year period; or (b) has been reviewed but not approved within the three-year period because protocol changes are required. Additionally, NIH should clarify whether the three-year review requirement will apply prospectively (i.e., to protocols first approved by the IBC after the Draft Policy is implemented), or retrospectively (i.e., to protocols first approved by the IBC prior the Draft Policy's implementation), and if the latter, the date by which existing IBC-approved protocols must receive de novo approval.

▪**Fifth Bullet Point ("Petitioning NIH for determination of the minimum . . ."):** The circumstances in which the petition process is to be used, and the operational details of the process are unclear.
Recommendation: NIH should clarify this provision in the following respects: (a) specify whether the petitioning mechanism is limited to human pathogens; (b) allow for the possibility that no biocontainment level will be required in the case of low-risk agents; (c) establish a timeline by which NIH will address the petitions that it receives; and (d) address how IBCs should handle cases in which the organisms in question cannot be identified past the genus level.

▪**Seventh Bullet Point ("Periodically reviewing approved . . ."):** It is unclear whether the "periodic review" specified in this provision is to be carried out in addition to the de novo review.
Recommendation: NIH should clarify if the periodic review is required in addition to the three-year de novo review, and if so, provide additional details on expectations for periodic review, including specification of the protocol sections/elements that require review. Along these lines, is periodic review necessary with a three-year de novo review requirement? If the 3-year de novo review requirement is maintained, NIH should consider the USDA's review

approach, which requires 3-year de novo review, but removed a previous requirement for annual continuing review. [9 CFR §2.31].

▪**Eighth Bullet Point ("Adopting plans which include . . . "):** The Draft Policy is unclear as to whether the IBC must formally adopt any institutional emergency response plans, many of which address areas outside of the IBC's scope.
Recommendation: NIH should clarify whether the IBC must formally adopt all institutional emergency response plans (i.e., in a manner similar to that in which protocols are approved), or whether IBC or BSO review of/consultation regarding the portions of institutional emergency response plans impacting IBC-regulated areas is sufficient.

▪**Tenth Bullet Point ("Reporting certain incidents . . ."):** The first sentence of this section states that reporting is required for incidents that pose a significant risk to human health. However, this modifying phrase is absent in the description of individual incidents that must be reported, thus creating confusion. For example, why would the lack of registration of a human cell line require 24-hour reporting, particularly if a lab were functioning at BSL2? Further, under the fourth sub-bullet point ("Any incidents involving exposures at BSL-2/ABSL-2) . . ."), it is unclear whether minor exposure to an agent not known to cause disease or a non-treatable BSL2 exposure requires reporting. Overall, the lack of clear reporting criteria and thresholds in this section will result in inconsistent reporting practices. For example, a non-biological occupational injury (e.g., back strain) that occurs inside a BSL-3 laboratory could technically be considered a "incident at a BSL-3 facility," but have no biosafety implications. Finally, the term "adventitious agent" (as used in the last sentence of this section) is undefined.
Recommendation: NIH should empower the IBC to determine in its policies and procedures which types of reported incidents require committee-level review, and which can be handled via reporting to and review by the BSO. Further, our organizations urge NIH to explicitly state that incidents are reportable to NIH only when the IBC determines that they are biologic in nature and pose a significant risk to human health, by making the following modifications to this section:

- **First Sentence:** Modify this sentence to read as follows: "Reporting certain incidents to NIH that the IBC has determined are biologic in nature and pose a significant risk to human health using the required reporting template.

- **Third Sentence:** Modify this sentence to read as follows: "This includes the incidents involving the factors listed below when the IBC has determined such incident is biologic in nature and poses a significant risk to human health:"
- **Fourth Sub-Bullet Point:** Clarify whether exposure to an agent not known to cause disease or untreatable exposures at BSL-2/ABSL-2 that the IBC has determined do not pose a significant risk to human health are reportable.

NIH should provide examples that clearly distinguish reportable and non-reportable events to promote consistent interpretation and reporting. Finally, NIH should include a definition for "adventitious agents" in the General Definitions section.

▪**Eleventh Bullet Point ("Reviewing certain lower-risk incidents . . . "):** If NIH intends for this policy to be a risk-based policy and to empower the IBC and BSO to provide appropriate oversight, it is unclear (1) why any incidents at BSL-1/ABSL-1 require mandatory reporting to/review by the IBC, as opposed to being handled via interaction with the BSO, with reporting to the IBC as the BSO determines is appropriate in accordance with institutional/IBC policies and procedures.

Recommendation: NIH should modify this bullet point and its two sub-bullet points to remove any references to BSL-1/ABSL-1 and to instead include the following statement:

> Incidents at BSL-1/ABSL-1 that (a) do not involve recombinant technology; and/or (b) that involve minor spills of low-risk agents that do not breach containment and that are properly cleaned and decontaminated in accordance with institutional policies and procedures, shall be handled by the researcher in conjunction with the BSO. The BSO shall report to the IBC any such incidents that require reporting under applicable institutional and/or IBC policies and procedures.

▪**Twelfth Bullet Point ("Posting all incident reports .. . . "):** This provision is unclear as to whether public posting is required for incidents that are not required to be reported to NIH.

Recommendation: NIH should modify the first sentence of this provision to read as follows: "Posting of all incident reports for those incidents that are required to be reported to NIH on a public-facing webpage on the website of the institution, using the required incident reporting template."

Biological Safety Officer: As written, the Draft Policy increases the BSO's responsibilities without a corresponding increase in authority or recognition of the subject matter expertise necessary to carry out the BSO's duties.
Recommendation: NIH should define the BSO's authority (e.g., authority to stop work conducted under an IBC approved protocol that poses a significant risk to human health), in addition to detailing responsibilities. Alternatively, the Draft Policy should make clear that the institution is empowered to delegate such authorities to the BSO as are necessary to carry out the responsibilities listed in the Draft Policy. Additionally, NIH should detail any minimum qualifications/competencies that it expects the BSO and/or "other official" assigned to take on these responsibilities to possess. Finally, it was noted that NIH eliminated large scale work (i.e., >10 L) as an independent trigger requiring a BSO, and questions were raised by our members as to whether this was an intentional omission.

Section, III-C, Responsibilities of the Principal Investigator: This section should make clear that the PI's responsibilities must be carried out within the framework of IBC and institutional policies and processes.
Recommendation: NIH should modify the first sentence of this section to read as follows: "The responsibilities of the PI include following all institutional and IBC policies and procedures including those governing the following duties:"

Section III-D, Responsibilities of the National Institutes of Health (NIH): The Draft Policy lists NIH responsibilities, but it lacks processes that NIH will follow in carrying out these responsibilities, including applicable timelines. Additionally, this section fails to include clear mechanisms for how NIH will directly communicate with assured institutions and registered IBCs.
Recommendation: NIH should provide details on the processes that it will follow in carrying out its responsibilities under this section, including associated timelines, particularly with respect to when NIH will provide decisions regarding containment levels, Biosafety Assurances, and incident reports. NIH should also include within its listed responsibilities an obligation to directly communicate with all assured institutions and registered IBCs regarding proposed policy changes and interpretations and provide ample time for comments. Additionally, NIH should establish a central webpage where all containment and other IBC-related determinations are posted.

Section IV, Categories of Oversight for Research Based on Risk: See comments below.

Section IV-1, Research that Requires NIH and IBC Approval Before Initiation: This section of the Draft Policy specifies the research and requests that must receive NIH approval, but it fails to provide details regarding the operational process for making these requests or how NIH will conduct its scientific review. Further, this section lacks any information concerning the timeline for decision-making by NIH, as well as any circumstances that warrant expedited decision-making.

Recommendation: NIH should provide templates outlining the information to be provided to the agency in connection with (a) review of research involving emerging/novel/zoonotic agents for which the risk group (RG) classification or minimum containment level is not available in the BMBL; (b) initial requests to lower containment for research involving wild type or genetically modified RG3 or RG4 biological agents; and (c) initial requests to lower containment below BSL-2 for research involving gene drive modified organisms (GDMOs). Additionally, NIH should consider initially spelling out the acronym "GDMO" and providing a definition for this term.

To assist institutions and IBCs in better understanding and preparing for the determination process, NIH should also detail how it will conduct its scientific review process, including a description of who will be involved in the process and their subject matter expertise, along with the objective assessment criteria that will be employed. Additionally, NIH should set forth expected review periods, including circumstances that justify expedited review requests, along with a process for IBCs/institutions to obtain status updates, and an escalation mechanism for when a determination is delayed beyond the stated period. Finally, NIH should also clarify whether an institution may proceed with research under interim containment requirements established by the IBC, pending receipt of the NIH determination.

Section IV-2, Research that Requires IBC Review and Approval Before Initiation: The research category listed under the fourth bullet point – "Research with primary cells that may be contaminated by adventitious agents" – is overly broad and includes research posing low-level risks that do not warrant mandatory review by the full IBC. For example, this category encompasses human primary cells, human tissues, human blood-derived materials, non-human primate tissues, and other primary materials that are routinely handled using universal precautions and/or following institutional exposure control plans/occupational health programs and OHSA requirements related to bloodborne pathogens.

Recommendation: As previously noted, NIH should include a definition for the

term "adventitious agents." Additionally, NIH should limit the scope of this category to primary cells with known or reasonably suspected contamination by adventitious agents that require specialized containment or response measures beyond universal precautions/OSHA bloodborne pathogen requirements. If NIH rejects these recommended limitations, it should, at the very least, allow for delegated review of activities falling within this category that are routinely conducted in accordance with established institutional controls.

Section IV-3, Research that Requires Review and Approval Before Initiation and May be Delegated to an Individual or Subgroup of IBC Members: The Draft Policy (a) omits the category of Exempt Experiments included in Section III-F of the current NIH Guidelines; (b) omits the category of low-risk experiments requiring only notice to the IBC under Section III-E of the NIH Guidelines; and (c) omits any exemption for transgenic rodents housed at ABSL-1. Instead, the Draft Policy requires delegated review for these low-risk activities resulting in a vastly increased IBC workload and unnecessarily hampering research activities without a corresponding increase in safety benefits. Rather than focusing on allocating IBC efforts and resources to higher-risk activities, the Draft Policy directs limited IBC, institutional, and agency resources to the review of research activities that pose so little risk that they would not even fall within the ambit of a truly risk-based policy.
Recommendation: As NIH has stated, a major goal of the Draft Policy is to establish a risk-based regulatory approach. Accordingly, NIH should retain the categories of exempt experiments and experiments requiring only notice to the IBC simultaneously with initiation as described in Sections III-E and III-F of the current NIH Guidelines.

Section V, Risk Assessment and Mitigation for Research Involving Biohazards: As previously noted the Draft Policy appears to inappropriately equate the terms "biohazard" and "biological agent," by requiring a risk assessment for "research involving ***biohazards***," but only providing a definition of the term "***biological agent.***" Additionally, the Draft Policy significantly expands the categories of research that fall within its scope, but it provides limited operational guidance that IBCs and institutions can use to ensure that mandated risk assessments are performed in an objective and consistent manner. The Draft Policy includes factors to consider in risk assessments, but it lacks any decision-making frameworks that IBCs can use when evaluating these risks and developing risk mitigation strategies. Finally, the use of the word "manipulation" in the phrase "Manipulations of the biohazard," is

confusing because manipulation can be used to refer to either changing the characteristics of the agent (which is addressed elsewhere in the policy) or the physical handling of the agent, which is the topic of this section.
Recommendation: As previously noted, NIH should provide a definition of the term "biohazard" that distinguishes it from "biological agent." NIH should also develop and provide additional tools that IBCs can use to promote objective and consistent risk assessments such as frameworks discussing how risks and benefits should be weighed and evaluated, sample containment determination examples, sample risk mitigation plans, case studies, and FAQs. Finally, NIH should replace the word "manipulations" with "handling."

Section V-A, Requirements and Consideration for Risk Assessment of the Characteristics of the Biohazard: No comments.

Section V-B Requirements and Consideration for Risk Assessment for Genetically Modified Biological Agents, Cells, or Organisms: No comments.

Section V-C, Requirements and Considerations for Risk Assessment for Synthetic Biological Agents or Emerging Technologies: No comments.

Section V-D, Requirements and Considerations for Risk Assessment of Manipulations of Biohazards: As previously noted, to avoid confusion, NIH should replace the word "manipulations" in this section with "handling."

Section V-E, Risk Mitigation Strategies and Laboratory Containment: As previously noted, in some cases GDMOs may be more stable than wild-type organisms, and thus it is unclear why the Draft Policy requires a minimum of BSL-2 for all research involving GDMOs.
Recommendation: NIH should delete the minimum BSL-2 containment requirement for GDMOs and empower IBCs to set an appropriate containment level based on the characteristics of the GDMO.

IBC Meeting Minutes Draft Template: The meeting minutes templates is overly detailed and prescriptive and serves only to impede minutes preparation by requiring reiteration in the minutes of details that are already included in other documentation (e.g., standard operating procedures, research protocols). Further, given that the Draft Policy encompasses non-NIH funded research conducted at institutions that receive NIH funding, the Draft Policy inadequately addresses the types of redactions that are appropriate in cases in which an institution's conduct of non-NIH funded research is subject

to confidentiality and non-disclosure obligations. Finally, the required level of detail in the minutes makes it extremely difficult, if not impossible, for institutions to meet the Draft Policy's deadline for having minutes prepared by the next convened IBC meeting, particularly at institutions that have multiple IBCs meeting frequently.

Recommendation: Our organizations urge NIH to withdraw the required template approach, and instead follow the approach to meeting minutes adopted by the Common Rule, and require only that the institution or IBC "prepare and maintain adequate documentation of all [IBC] activities" including "Minutes of [IBC] meetings, which shall be in sufficient detail to show attendance at the meetings; actions taken by the [IBC]; the vote on these actions including the number of members voting for, against, and abstaining; the basis for requiring changes in or disapproving research; and a written summary of the discussion of controverted issues and their resolution." [*See*, 45 CFR §46.115]. If NIH maintains the template approach, the agency should consider making the following changes to the template and process for keeping minutes:

- **Timing:** Allow for 90 days to prepare meeting minutes.
- **Redaction Principles:** The NIH's redaction standards do not take into account the fact that the Draft Policy encompasses research that NIH does not fund and that is frequently being conducted pursuant to a contract with a private entity that impose confidentiality and non-disclosure obligations on the institutions carrying out the research. These confidentiality and non-disclosure requirements often include proprietary or pre-patent information that is critical for IBC review, but the public disclosure of which has significant financial and legal implications for the sponsor. Our organizations remain concerned that NIH's inclusion of non-NIH funded research within the scope of the Draft Policy is inappropriate and without statutory authority. Should NIH continue with this approach, our organizations urge the agency to recognize within the template that institutions may cite contractual standards governing non-NIH funded research as the basis for redactions made in meeting minutes. To do otherwise would constitute undue interference with an institution's ability to contract with private entities to carry out research, merely because the institution accepts NIH funding on unrelated projects.
- **Incident Review**: It should be sufficient to include within meeting minutes the same level of detail regarding incidents that is required in public posting of those incidents.

Draft Incident Reporting Template: As with the minutes template, the incident reporting template is overly detailed and prescriptive, and requires the disclosure of information that may compromise the privacy of an individual involved in an incident and the security of research activities. Further, the requirement to publicly post such detailed information, including "root cause analysis," serves to discourage incident reporting and goes against efforts to replace a "blame culture" of incident reporting with a "fair and just culture" approach that facilitates and supports self-reporting.

Recommendation: Our organizations recommend that NIH abandon the mandated template (which is not in effect for either IRBs or IACUCs) and permit anonymized aggregated incident reporting. Alternatively, NIH should require institutions to only report on incidents that pose a significant risk to human health by supplying sufficient detail to provide notice of the event and follow-up corrective actions taken. If NIH retains the proposed incident reporting template, the agency should consider making the following changes:

- **Required Reports:** NIH should reference the provisions of Section III-B of the Draft Policy with respect to the incidents that must be reported instead of repeating this information in the template. The repeated information adds confusion, not clarity (e.g., "administrative failure" description is too broad to be helpful). Further, as previously noted, NIH should limit the incidents required to be reported to those that the IBC determines are biologic in nature and pose a significant risk to human health. This point should be made clear in the form instructions and in the section on incident information. NIH should also clarify if the reporting template is only used for reports to NIH, or if it must be used for internal institutional reporting as well.
- **PI's Name and Grant Information:** Remove the requirement for providing the PI's name, particularly if public posting is required. In labs that have only one or two workers, the posting of the PI's name could lead to identification of the person involved in the incident. For the same reason, grant information that can be used to identify the PI also should be removed prior to publication.

Conclusion: Our organizations appreciate the opportunity to provide comments on the Draft Policy. Our member institutions support robust biosafety review and oversight but have expressed concerns that the Draft Policy tilts too far in the direction of requiring numerous and complicated controls for low-risk research. Such an approach does not serve the cause of increased biosafety because it misallocates ever-more limited resources away

from the oversight of higher-risk activities, while unnecessarily burdening the conduct of low-risk activities. Accordingly, NIH should consider recalibrating its approach by modifying the Draft Policy to better enable IBCs and BSOs to provide independent, risk-based review and oversight. The recommendations expressed above will help to foster such an approach.

Finally, our organizations request that prior to the publication of a final policy, NIH will post for comment a revised draft of the policy that includes a summary of the comments it received and its basis for accepting/rejecting those comments.

Description: Commants provided during the First Regional Listening Session

Listening Session 1: NIH Hearing Comments (296 words)

Andrew Maksymowych, Biosafety Officer at the University of Pennsylvania.

These opinions are my own and do not necessarily represent the views of my employer

(1) The designation "Biosafety Modernization Initiative" is presumptuous. The Biosafety profession existed before the *NIH Guidelines* and will exist with or without guidance from the NIH.

(2) Science and technology have evolved, and the Biosafety profession has endeavored to keep pace. Programs do not exist exclusively to support the *NIH Guidelines*.

(3) Biosafety professionals are practicing "risk based" biosafety. It is the *NIH Guidelines* that have been stuck in the past. With that perspective this initiative is overdue and welcome.

(4) 21 Century Biosafety is not currently defined, nor will it be in the future, strictly by the NIH Policy. The OSP acknowledged that other Federal agencies may have different expectations for biosafety, independent from the new NIH Policy.

Step one, must be to define programmatic pillars for this policy:

(5) **Harmonization:** Will new NIH Policy be harmonized with international biosafety standards?

(6) **NIH Policy:** Must not confound the practice of biosafety.

(7) **Institutional Biosafety Committees:** Have evolved to address biosafety risk assessments beyond narrowly addressing NIH guidance. Are there expectations for significant operational changes?

Will the NIH detail expectations regarding IBC status within institutional compliance committee hierarchy, mandating institutional support and provision of adequate resources?

(8) **The Biosafety Profession:** Empowerment for Biosafety Programs from the NIH is welcome. What this may look like remains to be defined and must be coordinated by biosafety professionals.

(9) **Finally:** "Because we are dealing with the federal government" only Leadership is empowered to pursue such interactions. Guard against persistent tendencies for policy activities such as this to be appropriated by leadership. Consider preferentially, input from biosafety profession "boots on the ground".

Thank you!

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We have concerns about the scope of the policy. See attached letter which explains in more detail our concern about the definition of "genetic modification" as well as our specific suggestions for how to better define this term. In addition, we recommend a more workable oversight pathway for individualized and N-of-few genome-editing therapies.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): no comment

3. Continued utility of Risk Groups: no comment

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): no comment

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: no comment

Office of Science Policy
National Institutes of Health

Re: Request for Comment on Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Office of Science Policy:

On behalf of the Alliance for mRNA Medicines (AMM), we appreciate the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards (the Draft Policy). AMM supports strong, science-based biosafety oversight. We respectfully request two targeted changes to ensure that the Draft Policy is calibrated to actual risk and does not impede the development of mRNA medicines or individualized genome-editing therapies.

1. Clarify the definition of genetic modification

Concern:

The Draft Policy defines genetic modification to include the introduction of nucleic acid molecules that "can be transcribed or translated." Transcription and translation are normal functions of nucleic acids and, by themselves, do not alter the host cell's genome. As written, this criterion could classify synthetic mRNA and other non-integrating expression constructs—including mRNA vaccines and therapeutics—as genetic modification, even when their sole function is transient protein expression.

This language is also inconsistent with the Draft Policy's focus elsewhere on stable genomic alteration. Without a clear exclusion, a conservative institutional interpretation could bring routine, non-integrating mRNA research within biosafety oversight intended for materially different risks.

Recommendation

We recommend deleting the following criteria from the definition: "Have the potential for one or more cycles of replication in a cell; or Can be transcribed or translated." The replication criterion should likewise be deleted or narrowed to self-replicating or integrating elements, because non-integrating RNA replicons do not alter the host genome.

We further recommend replacing the definition of genetic modification with the following language:

> "Genetic modification: The introduction into cells, organisms, or viruses of nucleic acid molecules that possess biological properties enabling stable, heritable alteration of the genome (e.g., cis elements involved in integration, gene editing reagents, integrating or self-replicating viral elements); or the introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical, or radiological means. Nucleic acids that are transcribed or translated without altering the host genome, including synthetic messenger RNA and non-integrating expression constructs, are not genetic modification for purposes of this Policy, except where the encoded product is intended to produce stable, heritable alteration of the host genome."

The final clause appropriately preserves oversight for constructs encoding genome-editing tools whose intended function is to produce a stable genomic alteration, while keeping ordinary mRNA vaccines and therapeutics outside the definition.

2. Establish a workable oversight pathway for individualized and N-of-few genome-editing therapies

Concern

Section IV-2 of the Draft Policy requires IBC review and approval before clinical research involving deliberate administration of products capable of shedding, replicating, or integrating. The Draft Policy excludes a clinical product administered to one participant under an FDA-regulated individual-patient expanded access IND. That relief is too narrow for individualized and N-of-few genome-editing therapies.

As drafted, a platform protocol treating more than one patient, or a single patient treated under a conventional or platform IND, may require full IBC review before dosing. In addition, a patient-specific construct could require a new review whenever the change affects the biosafety assessment. This review cadence is poorly matched to validated platforms in which the manufacturing and administration process is common and only the targeting or editing sequence varies.

The Draft Policy also requires public posting of IBC meeting minutes. For a bespoke editing therapy, the construct can effectively be the product, so public disclosure should be carefully calibrated to protect confidential and proprietary information while preserving appropriate transparency.

Recommendation

We recommend extending the clinical exemption to individualized and small-cohort therapies delivered under any FDA-authorized IND, including conventional and platform INDs, where patient-specific variation is limited to the targeting or editing sequence within an otherwise validated platform. The Draft Policy should state:

> “Deliberate administration of an individualized or small-cohort clinical product under an FDA-regulated IND, where patient-specific variation is limited to the targeting or editing sequence within an otherwise validated platform, is not research subject to this Policy and does not require separate IBC review for each patient.”

We also recommend allowing an IBC to approve a validated genome-editing platform and its associated containment and biosafety practices through a master approval. Once that approval is in place, administration to additional participants whose constructs differ only in patient-specific targeting or editing sequence, within the approved risk assessment, should proceed upon notification to the IBC rather than through de novo review. The Draft Policy should state:

> “Where an IBC has approved a genome-editing platform and its associated containment and biosafety practices, administration to additional participants that differs only in patient-specific targeting or editing sequence, within the approved risk assessment, may proceed upon notification to the IBC and does not require a new approval.”

Conclusion

AMM does not seek to remove genome editing from oversight. Editor-encoding constructs intended to alter the genome should remain within the appropriate oversight framework. Our concern is that the Draft Policy, as written, imposes greater burdens on individualized and N-of-few therapies than on a one-off expanded access case without a corresponding difference in biosafety risk. A risk-calibrated pathway would preserve safety while helping bring these therapies to patients who cannot wait.

We appreciate NIH’s consideration of these targeted revisions. Thank you for the opportunity to comment on the Draft Policy.

Sincerely,

Clay Alspach
Executive Director
Alliance for mRNA Medicines

Uploaded File: 4-Biosafety-Policy-Comments-to-NIH-OSP-v2-1.docx

Description: Comments regarding omissions or non-addressed aspects of the NIH Draaft Biosafety Policy

Priority requests to NIH OSP Regarding Biosafety Policy Draft

- **<u>Certify Instutional Biosafety Program Compliance with Policy.</u>**

  1. Certification of **compliance** with the new NIH Biosafety Policy, and **confirmation of programmatic structure**, institutional **empowerment of Biosafety Program**, and **leadership position of Biosafety Officer** must become part of the grant application. Similar to animal program section.

- **<u>Define the minimum requirements for an Instutional Biosafety Program.</u>**

  1. Partial quote: '*. . . the National Institutes of Health (NIH) is committed to ensuring that* ***gold-standard science*** *is conducted under* ***gold-standard biosafety conditions****.*"
  A single, egregious oversite is that the requirement for a "Biosafety Officer" defaults to that listed in the current NIH Guidelines. How can an institution empower and run a "**gold-standard biosafety program"** without mandating a program lead that has significant biosafety experience?

  2. Pick a consistent title for the policy that reflects what the NIH wants / needs: Is this a "Biosafety Policy", a "Biosafety & Biosecurity Policy", or a "Policy for work with Biohazards"? Each of the titles will be interpreted differently by institutional leadership.
  This is important because the draft title "***Biosafety Policy for Research Involving Biohazards"*** (Biosafety & Biosecurity Policy?) does not address the fact that biosafety programs include a comprehensive administrative portfolio that includes research safety, compliance, ethics, training, committee review, and approval portfolio.

  3. Define what level of institutional empowerment must be granted to the Biosafety & Biosecurity program. Must both components be supported or is either one, biosafety or biosecurity, adequate to satisfy this policy?
  A biosafety officer or biosafety professional overseeing this gold standard biosafety program must be granted administrative level empowerment equivalent to the "Director of Animal Welfare", Director of Human Research Protections" or the "Institutional Veterinarian". A more appropriate role, to accomplish what the NIH is striving toward, will be Assistant or Associate Vice Provost or Vice President for Biosafety & Biosecurity Programs. Someone at the institutional leadership level, with appropriate biosafety experience, must be empowered to oversee these programs. **This must be mandated by the policy or it won't**

happen. Lack of this empowerment is currently what fails many biosafety programs.

- **Codify the Institutional Biosafety Committee (IBC)**

  1. Define what level of institutional support is adequate to satisfy policy requirements. Must Institutional resources include similar administrative structure for the IBC that is offered to the IRB and/or IACUC? What is the minimum? Office space, administrative support adequate for the number of IBC committees (or sub-committees), Leadership team consisting of Director, Associate Director, Professional staff separate from the biosafety program? For example, the Director of the IBC office has a separate role from Institutional Biosafety Officer, etc.? The Biosafety Officer sits as a voting member only?

- **Fully Embrace Risk-Based Biosafety**

  1. It is stated that this policy intends to encourage and embrace risk-based oversight and reporting. Yet, the only risk criteria incorporated into this first draft are Biological Agent Risk Groups and Biosafety Levels. These criteria are not applicable to all life science research activities or agents proposed for enhanced biosafety oversight. For example, biologics used in clinical trials cannot be defined by a biological agent Risk Group. Biologics are typically risk assessed by Risk Banding. Include/acknowledge this aspect of risk assessment in the updated draft. Alternatively, allow the biosafety professionals overseeing biosafety programs the freedom to perform risk assessment without specifying the risk criteria that must be used, because in biosafety and especially because of rapidly developing life sciences research programs, "it depends". Please let life science research professionals do what they do best, without restriction.

- **Risk-Based Biosafety**

  1. Since Biosafety Oversight mandated by the New NIH Biosafety Policy is supposed to be risk-based, registration, IBC review, and reporting of Biosafety Level 1 (BSL-1) or biologics band 1, materials and research, is a **NO GO**. Please exempt these low-risk materials from the Policy.

406. N/A

Uploaded File: 3-NIH-Biosafety-Policy-Comments-2.docx

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public confidence in NIH-supported science. I offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

Topic to Address*: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any

resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.

3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory

rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:
    a. the nature and stability of the genomic modification;
    b. whether the modification is heritable and the potential for transmission through breeding;
    c. effects on animal health, phenotype, host range, susceptibility, or disease;
    d. potential entry into breeding or food-production systems;
    e. potential environmental release or interaction with non-research animal populations;
    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and
    g. applicable federal, state, or other regulatory oversight.
2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.
3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.
4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

  deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the

Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

b. State explicitly that the Policy does not address non-biological hazards.

c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

  Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

  the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate, and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

  Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and

Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

I believe the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, I request that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, I welcome the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. I do not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. I recommend that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice

- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, I recommend a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with my earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*
- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. I recommend that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior

leadership;

2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply

another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.
NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, I kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. I encourage NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE

BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The

Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While I support appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes
6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions

throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as “any incident,” “loss of containment,” “significant problems,” and “minor spills... generally do not need to be reported,” and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report “potential releases involving facility and/or equipment failures even when redundant systems were functioning properly” would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure

in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: I recommend the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and

occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. I support preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

Name of Organization: Americans for Medical Progress

Type of Organization: Non-Profit Research Organization

Role: Other

Role - Other: Director of Communications and Science Policy

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): All work involving research with animals

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Americans for Medical Progress (AMP) appreciates the opportunity to provide comments on the National Institutes of Health's (NIH) Draft Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112) and its associated implementation resources.

AMP is a nonprofit organization dedicated to fostering public understanding of the essential role of animal research in advancing human and animal health. We work closely with biomedical research institutions and the broader scientific community to promote responsible research, openness, and the continued availability of the scientific resources needed to advance medical discoveries.

AMP supports NIH's efforts to modernize biosafety oversight and ensure that biomedical research is conducted under appropriate safety standards. Our comments focus on the policy's implications for animal research: the treatment of routine transgenic animal activities, risk-based incident reporting and public disclosure, coordination with existing oversight programs, and protections for research personnel. Overall, we encourage NIH to ensure that expanded oversight and reporting requirements meaningfully improve biosafety without unnecessarily diverting limited institutional resources to administrative activities that add little value to risk assessment or public safety.

Topic 1: Scope of Research Covered by the Policy

AMP recognizes NIH's decision to expand the policy beyond recombinant and synthetic nucleic acid molecules to all biohazards. Because the draft definition of biohazards includes genetically modified cells and organisms other than plants, and because the updated policy contains no exempt categories, the expanded scope would reach routine transgenic animal activities that are currently exempt from the current policy.

Under the current NIH Guidelines, the purchase or transfer of transgenic rodents and the generation of BL1 transgenic rodents through breeding are exempt (Appendices C-VI and C-VII). The updated draft policy instead lists research with transgenic organisms at BSL-1/ABSL-1 among the activities eligible for delegated review under Section IV-3, which requires approval before initiation and periodic re-approval. As drafted, the breeding, purchase, and transfer of BL1 transgenic rodent lines would therefore appear to require review and approval for the first time. Because these activities make up much of the day-to-

day work of transgenic rodent colonies, this change would subject a large volume of routine, low-risk activity to new approval requirements without any corresponding biosafety benefit.
NIH has identified reducing administrative burden for lower-risk research as a central objective of this modernization effort. Requiring new approvals for activities that are exempt today and raise no new biosafety concerns would run counter to that goal and divert Institutional Biosafety Committee (IBC) attention from higher-risk work. AMP recommends that NIH carry forward exemptions equivalent to Appendices C-VI and C-VII in the final policy or, at minimum, state explicitly that these activities do not require review absent a meaningful change in biosafety risk.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Topic 2: Structure of Tiered Oversight, Risk Calibration, Accountability, Transparency, and Administrative Burden
AMP supports NIH's goal of aligning federal and institutional oversight with the level of risk associated with particular research activities. However, we are concerned that the draft's incident reporting and public disclosure provisions for lower-risk animal research are not proportional to the risks involved.
Incident thresholds
Section III-B provides that "any incident involving research subject to the policy with an animal that is housed at BSL-1/ABSL-1 or BSL-2/ABSL-2 (e.g., bite, scratch, escape or improper disposition)" must be reported to and addressed by the IBC, even when it does not meet the threshold for NIH notification. The draft would also require institutions to publicly post every incident report, including those addressed entirely at the institutional level, and to keep them posted for a minimum of five years.
Animal bites, scratches, and escapes occur during routine animal care and do not, on their own, indicate a failure of biosafety practices or an elevated risk to human health. Many involve no exposure to, or release of, the biological agent under study and are already managed through occupational health, veterinary, and Institutional Animal Care and Use Committee (IACUC) processes. Requiring IBC action and public posting for each event would consume staff time for report preparation, committee coordination, and redaction review while adding little to biosafety risk assessment. That burden would fall most heavily on smaller institutions with limited biosafety, administrative, and legal staff.
The draft already applies this reasoning elsewhere. Section III-B states that minor spills of low-risk agents that involve no breach of containment and are properly cleaned up "generally do not need to be reported," and that treatment for adventitious agents does not trigger NIH reporting unless a laboratory-acquired infection results. AMP recommends that NIH apply the same principle to animal incidents: bites, scratches, and escapes at ABSL-1 or ABSL-2 that involve no exposure to or release of the agent under study should be documented through existing institutional procedures rather than requiring IBC action and public posting.
Public disclosure
AMP encourages NIH to distinguish more clearly between incidents that warrant institutional documentation and those that warrant public disclosure. Rather than requiring publication of every incident subject to IBC review, NIH should establish risk-based thresholds for posting. For incidents below that threshold, a periodic summary describing the general nature of incidents, their biosafety significance, and corrective actions taken would support meaningful transparency without unnecessary disclosure of sensitive research and personnel information.
Coordination with IACUCs
The draft states that it seeks to "reinforce consistency with Institutional Review Boards and Institutional Animal Care and Use Committees," but the policy text does not define a role for IACUCs or address how IBC and IACUC responsibilities interact. Institutions already maintain processes for reviewing animal-

related incidents, occupational injuries, veterinary care, and personnel training. AMP recommends that the final policy expressly allow institutions to coordinate IBC and IACUC reviews and rely on shared documentation, rather than maintain parallel reporting and approval processes for the same event.
Personnel security
Transparency requirements must also account for the safety and security of research personnel. The draft incident reporting and IBC meeting minutes templates provide that information widely available from other public sources, including principal investigator names, biological agents, and grant numbers, may not be redacted. While each item may be individually accessible, compiling it alongside details about animal research activities, incidents, and institutional procedures creates a cumulative disclosure that can heighten security risks.
Scientists and staff involved in animal research continue to face harassment, threats, and other security incidents. AMP encourages NIH to recognize these risks explicitly in its redaction guidance and to allow institutions, in consultation with appropriate security personnel, to withhold information when disclosure could create credible risks to individuals, research facilities, or institutional operations, even when some of that information is otherwise publicly available.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Topic 4: Effectiveness of Compliance and Enforcement Mechanisms, Including Biosecurity Challenges
AMP supports NIH's interest in strengthening compliance and promoting public confidence in biomedical research oversight. We recommend a proportionate approach that distinguishes serious biosafety violations from minor incidents that are promptly identified, documented, and addressed through established institutional procedures.
AMP welcomes the proposed National Biosafety Data and Safety Analysis Center and NIH's commitment that voluntary, confidential near-miss reports would not be used for enforcement. Effective biosafety programs depend on a culture in which personnel report minor incidents and near misses promptly and without fear of disproportionate consequences. Mandatory public posting of low-risk, institution-level animal incidents could work against that culture, because personnel may be less willing to report minor events if each report becomes a public record associated with their laboratory for at least five years. Aligning the treatment of low-risk incidents with the non-punitive approach NIH has proposed for near misses would better support the reporting culture NIH seeks to build.
Regarding biosecurity, AMP notes that the security challenges facing animal research institutions extend beyond protecting biological agents to the physical safety of personnel and facilities, as discussed under Topic 2. We encourage NIH to treat personnel and facility security as part of its biosecurity considerations when finalizing disclosure requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Topics 5 and 6: Implementation Resources, Additional Guidance, and Draft Templates
AMP appreciates NIH's development of standardized incident reporting and IBC meeting minutes templates, which may improve consistency across institutions. We encourage NIH to address the following before the templates become mandatory:
• Consistency with Section III-B: Section III-B distinguishes incidents requiring NIH notification from

lower-risk incidents addressed by the IBC. However, the draft “Incident Reporting Template” states that "completed reports must be sent to NIH" and includes a field for the date of submission to NIH, while elsewhere referring to cases "when the report is required to be submitted to NIH." NIH should reconcile these provisions, clarify the documentation requirements for each category, and confirm that incidents below the NIH notification threshold may be maintained in institutional records without federal submission.

• Redaction guidance: Revise the redaction instructions in both templates to permit institutions to withhold information, including otherwise public information, when institutional security personnel determine that its compilation alongside incident details creates a credible risk to individuals or facilities, as discussed under Topic 2.

• Animal research examples: Provide examples of completed templates for common animal research scenarios, such as minor occupational injuries and animal escapes, including incidents already investigated through IACUC or occupational health programs. The incident template includes an "animal bite/scratch" option but no specific category for animal escapes.

• Transgenic animal activities: Clarify how delegated review under Section IV-3 would apply to transgenic animal research, consistent with our recommendation under Topic 1.

We also encourage NIH to engage laboratory animal veterinarians, IACUC administrators, animal care program leadership, and institutional biosafety professionals in developing these resources. Their practical experience will help ensure the final requirements are effective, workable, and consistent with existing animal welfare and oversight obligations.

Conclusion

AMP appreciates NIH's commitment to strengthening biosafety oversight and developing a framework that reflects the evolving nature of biomedical research.

We encourage NIH to ensure that the final policy balances meaningful transparency and accountability with appropriate protections for research personnel, recognizes existing institutional oversight systems, and maintains reporting requirements proportionate to the risks involved.

Description: PDF copy of AMP's Response to NOT-OD-26-112

October 19, 2026

Lyric Jorgenson, PhD
Associate Director for Science Policy
National Institutes of Health

Re: NOT-OD-26-112 - Draft NIH Biosafety Policy for Research Involving Biohazards

Submitted via submission portal and e-mail (SciencePolicy@od.nih.gov)

Dear Dr. Jorgenson,

Americans for Medical Progress (AMP) appreciates the opportunity to provide comments on the National Institutes of Health's (NIH) Draft Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112) and its associated implementation resources.

AMP is a nonprofit organization dedicated to fostering public understanding of the essential role of animal research in advancing human and animal health. We work closely with biomedical research institutions and the broader scientific community to promote responsible research, openness, and the continued availability of the scientific resources needed to advance medical discoveries.

AMP supports NIH's efforts to modernize biosafety oversight and ensure that biomedical research is conducted under appropriate safety standards. Our comments focus on the policy's implications for animal research: the treatment of routine transgenic animal activities, risk-based incident reporting and public disclosure, coordination with existing oversight programs, and protections for research personnel.

Overall, we encourage NIH to ensure that expanded oversight and reporting requirements meaningfully improve biosafety without unnecessarily diverting limited institutional resources to administrative activities that add little value to risk assessment or public safety.

Topic 1: Scope of Research Covered by the Policy

AMP recognizes NIH's decision to expand the policy beyond recombinant and synthetic nucleic acid molecules to all biohazards. Because the draft definition of biohazards includes genetically modified cells and organisms other than plants, and because the updated policy contains no exempt categories, the expanded scope would reach routine transgenic animal activities that are currently exempt from the current policy.

Under the current NIH Guidelines, the purchase or transfer of transgenic rodents and the generation of BL1 transgenic rodents through breeding are exempt (Appendices C-VI and C-VII). The updated draft policy instead lists research with transgenic organisms at BSL-1/ABSL-1 among the activities eligible for delegated review under Section IV-3, which requires approval before initiation and periodic re-approval. As drafted, the breeding, purchase, and transfer of BL1 transgenic rodent lines would therefore appear to require review and approval for the first time. Because these activities make up much of the day-to-day work of transgenic rodent colonies, this change would subject a large volume of routine, low-risk activity to new approval requirements without any corresponding biosafety benefit.

NIH has identified reducing administrative burden for lower-risk research as a central objective of this modernization effort. Requiring new approvals for activities that are exempt today and raise no new biosafety concerns would run counter to that goal and divert Institutional Biosafety Committee (IBC) attention from higher-risk work. AMP recommends that NIH carry forward exemptions equivalent to Appendices C-VI and C-VII in the final policy or, at minimum, state explicitly that these activities do not require review absent a meaningful change in biosafety risk.

Topic 2: Structure of Tiered Oversight, Risk Calibration, Accountability, Transparency, and Administrative Burden

AMP supports NIH's goal of aligning federal and institutional oversight with the level of risk associated with particular research activities. However, we are concerned that the draft's incident reporting and public disclosure provisions for lower-risk animal research are not proportional to the risks involved.

Incident thresholds

Section III-B provides that "any incident involving research subject to the policy with an animal that is housed at BSL-1/ABSL-1 or BSL-2/ABSL-2 (e.g., bite, scratch, escape or improper disposition)" must be reported to and addressed by the IBC, even when it does not meet the threshold for NIH notification. The draft would also require institutions to publicly post every incident report, including those addressed entirely at the institutional level, and to keep them posted for a minimum of five years.

Animal bites, scratches, and escapes occur during routine animal care and do not, on their own, indicate a failure of biosafety practices or an elevated risk to human health. Many involve no exposure to, or release of, the biological agent under study and are already managed through occupational health, veterinary, and Institutional Animal Care and Use Committee (IACUC) processes. Requiring IBC action and public posting for each event would consume staff time for report preparation, committee coordination, and redaction review while adding little to biosafety risk assessment. That burden would fall most heavily on smaller institutions with limited biosafety, administrative, and legal staff.

The draft already applies this reasoning elsewhere. Section III-B states that minor spills of low-risk agents that involve no breach of containment and are properly cleaned up "generally do not need to be reported," and that treatment for adventitious agents does not trigger NIH reporting unless a laboratory-acquired infection results. AMP recommends that NIH apply the same principle to animal incidents: bites, scratches, and escapes at ABSL-1 or ABSL-2 that involve no exposure to or release of the agent under study should be documented through existing institutional procedures rather than requiring IBC action and public posting.

Public disclosure

AMP encourages NIH to distinguish more clearly between incidents that warrant institutional documentation and those that warrant public disclosure. Rather than requiring publication of every incident subject to IBC review, NIH should establish risk-based thresholds for posting. For incidents below that threshold, a periodic summary describing the general nature of incidents, their biosafety significance, and corrective actions taken would support meaningful transparency without unnecessary disclosure of sensitive research and personnel information.

Coordination with IACUCs

The draft states that it seeks to "reinforce consistency with Institutional Review Boards and Institutional Animal Care and Use Committees," but the policy text does not define a role for IACUCs or address how IBC and IACUC responsibilities interact. Institutions already maintain processes for reviewing animal-related incidents,

occupational injuries, veterinary care, and personnel training. AMP recommends that the final policy expressly allow institutions to coordinate IBC and IACUC reviews and rely on shared documentation, rather than maintain parallel reporting and approval processes for the same event.

Personnel security

Transparency requirements must also account for the safety and security of research personnel. The draft incident reporting and IBC meeting minutes templates provide that information widely available from other public sources, including principal investigator names, biological agents, and grant numbers, may not be redacted. While each item may be individually accessible, compiling it alongside details about animal research activities, incidents, and institutional procedures creates a cumulative disclosure that can heighten security risks.

Scientists and staff involved in animal research continue to face harassment, threats, and other security incidents. AMP encourages NIH to recognize these risks explicitly in its redaction guidance and to allow institutions, in consultation with appropriate security personnel, to withhold information when disclosure could create credible risks to individuals, research facilities, or institutional operations, even when some of that information is otherwise publicly available.

Topic 4: Effectiveness of Compliance and Enforcement Mechanisms, Including Biosecurity Challenges

AMP supports NIH's interest in strengthening compliance and promoting public confidence in biomedical research oversight. We recommend a proportionate approach that distinguishes serious biosafety violations from minor incidents that are promptly identified, documented, and addressed through established institutional procedures.

AMP welcomes the proposed National Biosafety Data and Safety Analysis Center and NIH's commitment that voluntary, confidential near-miss reports would not be used for enforcement. Effective biosafety programs depend on a culture in which personnel report minor incidents and near misses promptly and without fear of disproportionate consequences. Mandatory public posting of low-risk, institution-level animal incidents could work against that culture, because personnel may be less willing to report minor events if each report becomes a public record associated with their laboratory for at least five years. Aligning the treatment of low-risk incidents with the non-punitive approach NIH has proposed for near misses would better support the reporting culture NIH seeks to build.

Regarding biosecurity, AMP notes that the security challenges facing animal research institutions extend beyond protecting biological agents to the physical safety of personnel and facilities, as discussed under Topic 2. We encourage NIH to treat personnel and facility security as part of its biosecurity considerations when finalizing disclosure requirements.

Topics 5 and 6: Implementation Resources, Additional Guidance, and Draft Templates

AMP appreciates NIH's development of standardized incident reporting and IBC meeting minutes templates, which may improve consistency across institutions. We encourage NIH to address the following before the templates become mandatory:

- Consistency with Section III-B: Section III-B distinguishes incidents requiring NIH notification from lower-risk incidents addressed by the IBC. However, the draft “Incident Reporting Template” states that "completed reports must be sent to NIH" and includes a field for the date of submission to NIH, while elsewhere referring to cases "when the report is required to be submitted to NIH." NIH should reconcile

these provisions, clarify the documentation requirements for each category, and confirm that incidents below the NIH notification threshold may be maintained in institutional records without federal submission.

- Redaction guidance: Revise the redaction instructions in both templates to permit institutions to withhold information, including otherwise public information, when institutional security personnel determine that its compilation alongside incident details creates a credible risk to individuals or facilities, as discussed under Topic 2.
- Animal research examples: Provide examples of completed templates for common animal research scenarios, such as minor occupational injuries and animal escapes, including incidents already investigated through IACUC or occupational health programs. The incident template includes an "animal bite/scratch" option but no specific category for animal escapes.
- Transgenic animal activities: Clarify how delegated review under Section IV-3 would apply to transgenic animal research, consistent with our recommendation under Topic 1.

We also encourage NIH to engage laboratory animal veterinarians, IACUC administrators, animal care program leadership, and institutional biosafety professionals in developing these resources. Their practical experience will help ensure the final requirements are effective, workable, and consistent with existing animal welfare and oversight obligations.

Conclusion

AMP appreciates NIH's commitment to strengthening biosafety oversight and developing a framework that reflects the evolving nature of biomedical research.

We encourage NIH to ensure that the final policy balances meaningful transparency and accountability with appropriate protections for research personnel, recognizes existing institutional oversight systems, and maintains reporting requirements proportionate to the risks involved.

Thank you for considering these comments and for the opportunity to contribute to this important policy discussion.

Sincerely,

Paula Clifford, MLA, RLATG, CVT

Comment to NOT-OD-26-112

I appreciate NIH's sustained engagement with the research community and supports the goal of a modern, risk-based biosafety framework that is transparent, adaptive, and accountable. The draft policy makes meaningful progress by expanding attention beyond recombinant and synthetic nucleic acid research, clarifying several incident-reporting thresholds, permitting delegated review for specified lower-risk activities, and recognizing the need for implementation resources.

At the same time, the proposed policy would substantially expand institutional scope, review, documentation, public-posting, assurance, and reporting obligations. In its current form, it does not provide proportionate authority, resources, training infrastructure, or implementation time for institutions, IBCs, and biosafety professionals expected to carry out those responsibilities. The result could be increased administrative burden without a corresponding improvement in risk reduction, particularly for routine low-risk research and for smaller or less-resourced institutions.

Priority Recommendations

Issue	Requested NIH action
Scope and definitions	Define key terms with sufficient precision to support consistent institutional determinations. Specifically, define *biohazard* and revise the definitions of *biological agent*, *toxin*, *genetic modification*, *laboratory*

Issue	Requested NIH action
	research, and *genetically modified organism (GDMO)* to ensure the policy's scope is internally consistent, risk based, and aligned with its intended oversight objectives.
Low-risk research	Allow research institutions the flexibility to regulate low-risk research according to their own risk assessments and processes without mandatory delegated IBC approval.
Federal versus local review	Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow IBCs to rely on published NIH precedents.
IBC and BSO authority	Pair expanded responsibilities with explicit authority, independence, access, escalation, and institutional support.
Transparency	Replace universal public posting of detailed minutes and incident reports with standardized, de-identified public summaries and clear redaction rules.
Incident reporting	Retain clear federal thresholds, clarify overlapping categories, and preserve confidential near-miss reporting and local management of lower-risk events. Allow flexible templates to account for institutional needs.
Implementation	Provide final templates, training, databases, examples, and assurance guidance before implementation; use pilots and a minimum 24-month phased transition.

1. Scope of Research Covered by the Policy

Define the boundary of the policy

The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.

Use internally consistent terminology

The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.

Clarify plant and animal coverage

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk

and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Calibrate toxin and protein scope to meaningful risk

The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and other self-aggregating proteins” in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

“Biomedical research” should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported “in full” at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee’s role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish

exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Risk Assessment and the Continued Utility of Risk Groups

Retain Risk Groups as a starting point

Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.

Distinguish genetic engineering from other forms of change

The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.

Avoid rigid containment rules that conflict with risk assessment

A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Roles, Responsibilities, Compliance, and Transparency

Align accountability with authority

The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.

Provide procedures for managing overlapping federal policies

The draft says research also under another federal agency's regulation or purview "may proceed under

the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.

Assign institutional responsibilities appropriately

The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.

Clarify governance requirements

A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure,"

“compliance violation,” and “minor spill.” The policy should clarify whether precautionary post exposure prophylactic treatment is considered “agent-specific treatment”. It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents.

5. Implementation Resources, Timeline, and Funding

Provide a minimum 24-month phased implementation period

The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.

Pilot the policy and templates

NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.

Develop implementation resources

Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.

Address the cost of compliance

The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures,

workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

Allow flexible institutional models

The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Requested Clarifications and Targeted Revisions

Recommend that NIH address the following items expressly in the final text or in binding implementation guidance:

- Define biohazard and clearly state the policy's treatment of animal-only pathogens, plant pathogens, genetically modified plants, greenhouse research, environmental release, toxins, and disease-associated self-propagating proteins.
- Clarify whether another federal agency's approval substitutes for NIH-policy oversight, satisfies a portion of the NIH requirements, or operates concurrently with IBC review.
- Establish an explicit precedence rule between Sections IV-1, IV-2, and IV-3 and state how de novo renewals are categorized. Create an exempt category section for lower risk agents such as transgenic organisms at BSL1.
- Define when a prior NIH containment determination may be used by another institution without a new petition.
- Specify the institutional authority, independence, and access expected for a BSO or alternate official performing BSO duties.
- Define allowable and required redactions and replace detailed public disclosures with de-identified summaries wherever possible.
- Clarify the review and public-reporting expectations for lower-risk animal incidents, first-aid events, minor spills, and compliance violations that do not present a meaningful safety risk.
- Provide a transition mechanism for Biosafety Assurance approval so ongoing covered research is not halted because NIH review is incomplete on the effective date.

A final policy should be clear in scope, calibrated to meaningful risk, harmonized with other federal requirements, and workable across institutions with widely differing resources. It should empower qualified local expertise, reserve federal preapproval for well-defined high-risk or uncertain circumstances, protect a strong reporting culture, and provide sufficient tools, funding, and transition time for sustainable implementation.

Uploaded File: 1-Recommendations-to-the-NIH-OSP-2.docx

I ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

1. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts;

compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

2. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure

implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological

exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

3. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

4. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

5. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

6. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and

explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

7. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions.

Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Failure to include plants which can negatively impact the local environment, not just those with the potential to cause immediate harm to humans, should be included. (non-native species, or modified plants with the potential to alter or replace non-modified local flora) Not all harm is immediate.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Having templates for meeting minutes is beneficial to create uniformity. A great deal still needs to be clarified about level of detail required, and ability to redact. Often detail conflicts with confidentiality of research lines and false alarm can be generated where members of the public reading the document may lack context to understand the research.

The template for incident reporting is far too much for minor incidents. It will create a huge administrative burden for what are essentially the office equivalent of paper cuts. It will likely also result in non-reporting. A separate, much less detailed incident report, or better yet, not requiring a report for minor incidents, is called for.

6. Other feedback relevant to this resource: Please see attached.

Subject: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Personal Commentary and Support for CSHEMA and BSAA Recommendations

To Whom It May Concern:

I am submitting this comment in response to the National Institutes of Health (NIH) effort to modernize and strengthen the oversight of biosafety.

While I support the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA) and the Biosafety Administrators Association (BSAA) regarding this effort, there are a few areas in which I would like to add a bit more emphasis.

Delegated Member Review – thank you for this, it is much needed. However, it makes little sense, and a great deal more expense to institutions, to offer this option then have the same information be reviewed at a full committee meeting. A preferable scenario would be that the proposal goes out to the full committee to read and provide opportunity for any member to request that it be full committee review. Absent anyone requesting FCR, the DMR should be sufficient and not require an additional review during an IBC meeting.

Public posting of minor incidents could have a chilling effect on research in the United States. A cut from a slide, or a scratch from a mouse, especially when students are learning how to handle slides and rodents, are incredibly common and akin to receiving a paper cut while filing. Much of the public is unaware of this fact, and posting minor incidents that involve nothing more than basic first aid could all to easily result in misinterpretation and condemnation. Afraid of the that, people may choose to not report. Or PIs may choose to stop teaching students in their labs, setting up scenarios where students in the US won't have the same experience and opportunities, leaving them less qualified for the job market and graduate school education. There is no justifiable reason for this, especially when records can be kept internally and be made available to NIH upon request. I strongly urge NIH to reconsider the proposal to publicly post minor incidents.

Payment to Community Members. I applaud NIH for strengthening oversight to include toxins, infectious agents, etc., but there will be large scale increase in the amount of work a biosafety committee has as a result. It is difficult enough to find community members willing to give up their time to serve, as it is, but to increase the workload without allowing some form of honorarium or stipend to cover their time and travel expense (gas is expensive!) will make it nearly impossible for IBCs to find and maintain community members. Both IRBs and IACUCs offer honoraria for their community member's service, the IBC should as well.

Both the BSAA's and CSHEMA's comments appropriately reflect the needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

As an individual, my work as Regulatory Compliance Administrator for Research and Education would be directly impacted by a new NIH policy on biosafety and I support the recommendations outlined by both organizations.

Thank you for the opportunity to comment.

Sincerely,

Cheryl McGraw
Regulatory Compliance Administrator for Research and Education

411. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Scope of Research Covered by the Policy
Define the boundary of the policy
The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define “biohazard.” The operative scope instead combines a human-health risk threshold with selected categories of materials. This leaves uncertainty for materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions that require IBCs to assess environmental and population effects. NIH should define “biohazard” and state clearly whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework.
Use internally consistent terminology
The definition of “biological agent” is limited to bacteria, viruses, fungi, or parasites that cause human disease, although the term is used elsewhere in connection with RG1 materials, zoonotic agents, genetically modified agents, and agents of uncertain pathogenicity. CSHEMA recommends a neutral definition of biological agent, with a separate risk-based definition for a biohazardous agent. NIH should also define GDMO consistently and reconcile references to gene drive modified organisms, gene drive modified biological agents, and GDMOs.
Clarify plant and animal coverage
The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another agency satisfies NIH policy obligations and when concurrent IBC review remains required.
Calibrate toxin and protein scope to meaningful risk
The draft appears to cover all toxins and to require delegated review of non-Select Agent toxin proteins without a de minimis quantity, potency, concentration, or activity threshold. It also uses “prions and

other self-aggregating proteins" in ways that could be read more broadly than the disease-associated definition. NIH should distinguish biological toxins from other hazardous proteins; address inactive derivatives, subunits, and nucleic acids encoding toxins; establish risk-based thresholds or exemptions; and limit the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials.

Separate scientific definitions from policy applicability

"Biomedical research" should be defined by the nature and purpose of the activity, not by whether it occurs at an NIH-funded institution. Applicability to non-NIH-funded research at recipient institutions should be addressed separately. Likewise, clinical research involving biohazards should be defined independently rather than forced into a laboratory setting described by BSL or ABSL terminology.

Clarify policy application on existing IBC approvals

NIH must define a process for managing research with existing IBC approvals. For example, organisms without a risk group assignment or biosafety level guidance in the BMBL, but an institutional IBC has assigned containment levels based on risk assessment and literature support.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered Oversight and Calibration to Risk

Create a clear precedence rule

Sections IV-2 and IV-3 overlap. Genetically modified cells, viruses, and organisms appear in the full committee category, while several subsets of the same work appear in the delegated category. The final policy should state expressly that the most specific category controls and should provide a decision table with examples for full committee review, delegated review, registration, exemption, and NIH review.

Ensure delegated review actually streamlines oversight

Delegated review is a welcome modernization, but requiring every approval to be reported "in full" at the next IBC meeting and included in publicly posted minutes may recreate much of the workload the pathway is intended to avoid. Institutions should be permitted to provide a concise approval log or aggregate report to the IBC, with records retained for audit. The full committee's role after delegated approval should also be defined.

Remove mandatory review of routine minimal-risk activities

Commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should not automatically require IBC member review when a documented institutional screening process determines that they present minimal biosafety risk. NIH should establish exemptions or administrative registration pathways and permit institutions to elevate work when local circumstances warrant.

Limit federal review to clearly defined circumstances

Requiring NIH approval whenever an emerging, novel, or zoonotic agent lacks a Risk Group classification or minimum containment recommendation in the BMBL could capture many uncommon agents currently routinely handled at both BL1 and BL2, for example organisms discovered during environmental screens. NIH should define the trigger narrowly, permit qualified IBCs to make interim or final determinations for well-characterized agents, and reserve NIH preapproval for circumstances involving substantial uncertainty or potentially significant public or environmental consequences.

Make NIH precedents reusable

NIH should create a searchable national determination and risk-classification database and define substantial equivalence, permissible deviations, documentation expectations, and who determines

whether a prior decision applies. The draft anticipates publication of approved lower-containment determinations but does not state whether another institution may rely on them.

3. Continued utility of Risk Groups: Risk Assessment and the Continued Utility of Risk Groups
Retain Risk Groups as a starting point
Risk Groups remain useful for hazard communication and initial characterization, but they should not independently dictate containment or review level. The final policy should preserve experiment-specific and site-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations.
Distinguish genetic engineering from other forms of change
The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means. This could bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory oversight without a demonstrated increase in biosafety risk. NIH should distinguish deliberate genetic engineering from selection, adaptation, reassortment, and induced mutagenesis and assign oversight based on the resulting phenotype and risk.
Avoid rigid containment rules that conflict with risk assessment
A universal minimum of BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow equivalent risk-based containment and provide technology-specific guidance. Influenza language should also specify which segments, proportions, phenotypes, and virus types trigger BSL-3 enhanced containment rather than using language that could apply to any construct containing any listed segment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Roles, Responsibilities, Compliance, and Transparency
Align accountability with authority
The policy expands BSO and IBC responsibilities without defining corresponding authority. BSOs and IBCs should have explicit access to facilities and relevant records, direct reporting and escalation pathways, authority to require corrective measures, and authority to stop or suspend unsafe work when necessary.
Provide procedures for managing overlapping federal policies
The draft says research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" after approvals or clearances are obtained. This conflicts with the later statement that clinical research cannot begin until IBC and all other institutional and regulatory approvals are obtained, which clearly contemplates cumulative oversight. The final policy should explain when oversight by another agency satisfies NIH policy obligations and when concurrent IBC review remains required.
Assign institutional responsibilities appropriately
The PI can ensure proper use of equipment and report deficiencies, but may not control building ventilation, certification contracts, capital repairs, emergency power, or central maintenance. The final policy should allocate responsibility among the institution, program leadership, facilities owner, BSO, PI, and equipment user. Occupational health requirements should likewise include clear triggers, assigned authorities, and responsibility for developing and communicating required procedures.
Clarify governance requirements
A member who is recused because of a conflict should not count toward the quorum needed for action on that matter. NIH should specify the quorum and voting denominator after recusal, as well as expectations for remote participation, use of ad hoc consultants, and reasonable approaches for

institutions that have difficulty recruiting unaffiliated members.

Recalibrate public posting

Public posting of detailed IBC minutes and all incident reports could expose proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, where identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.

Define redaction and timing rules

If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. The NIH must also establish a defined endpoint for NIH's "final response." Institutions should not be held to a posting deadline that depends on an open-ended federal review.

Map retention requirements to record types

The final policy should include a record-retention table for protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. The table should identify the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident Reporting and Safety Learning

Preserve the clearer federal reporting thresholds

CSHEMA supports the draft's effort to identify specific categories for immediate notification and follow-up reporting. Clear thresholds and examples can improve consistency and allow NIH to focus on events with potential public health or community significance.

Resolve overlapping and undefined categories

The draft should define "incident," "basic first aid," "agent-specific treatment," "potential exposure," "compliance violation," and "minor spill." The policy should clarify whether precautionary post exposure prophylactic treatment is considered "agent-specific treatment". It should clarify whether any event at BSL-3 or BSL-4 is reportable regardless of relevance to biohazard containment and distinguish administrative noncompliance from events presenting an actual biosafety risk. Administrative noncompliance and low risk items should not necessitate a 24-hour reporting timeframe.

Keep reporting of lower-risk events within local IBC purview

NIH should not require every internally reviewed minor event to be publicly posted with unredacted identifying information. Institutions should retain authority to manage lower-risk events and near misses through local IBC review systems.

Use aggregate public reporting

The information required for public posting of incident reports may inadvertently provide enough information to identify the individual(s) involved, potentially resulting in unintentionally violating federal rules about disclosure of medical information. To address this and the issues listed above related to public posting, NIH should develop a confidential, de-identified national reporting system that can support trend analysis and shared learning. This system is only useful if its boundaries are clear and if both institutions and researchers trust that voluntary submissions will not be used for enforcement. NIH

should publish annual de-identified summaries, trends, contributing factors, and lessons learned. This approach would improve transparency and safety learning without attaching names or institutions to routine, well-managed incidents

6. Other feedback relevant to this resource: Implementation Resources, Timeline, and Funding
Provide a minimum 24-month phased implementation period
The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.
Pilot the policy and templates
NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory. 6
CSHEMA | Public Comment
Develop implementation resources
Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.
Address the cost of compliance
The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.
Allow flexible institutional models
The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

Description: Comments from ABSA

ABSA International — The Association for Biosafety and Biosecurity

Organization:	ABSA International 1200 Allanson Road, Mundelein, IL 60060 Phone: (866) 425-1365 | Email: info@absa.org | Web: www.absa.org
Date:	October 19, 2026
To:	Office of Science Policy National Institutes of Health 6705 Rockledge Drive, Suite 750, Bethesda, MD 20892
Submission Portal:	Submitted via NIH OSP Electronic Comment Portal
Subject / Notice:	Formal Public Comments and Recommendations on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice Number: NOT-OD-26-112)

ABSA International, the Association for Biosafety and Biosecurity, is a nonprofit professional association representing biosafety and biosecurity professionals in the United States and internationally. Our membership spans academic and research institutions, government laboratories, biotechnology companies, healthcare organizations, public health agencies, and consulting practices. Members bring scientific, technical, operational, and regulatory expertise across diverse biological research and laboratory settings.

ABSA's comments reflect the practical experience of professionals responsible for translating biosafety policy into daily practice. Our members conduct risk assessments, support Institutional Biosafety Committees (IBCs), develop training and containment practices, investigate incidents, and advise institutions on compliance. They understand how policy requirements affect laboratory safety, reporting culture, institutional resources, and the conduct of research.

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public

confidence in NIH-supported science. ABSA supports NIH's efforts to strengthen biosafety oversight. We offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

***Topic to Address**: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:

    a. the nature and stability of the genomic modification;

    b. whether the modification is heritable and the potential for transmission through breeding;

    c. effects on animal health, phenotype, host range, susceptibility, or disease;

    d. potential entry into breeding or food-production systems;

    e. potential environmental release or interaction with non-research animal populations;

    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and

    g. applicable federal, state, or other regulatory oversight.

2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

    Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

ABSA International believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, ABSA International requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, ABSA International welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. ABSA International does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. ABSA International recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, ABSA International recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with ABSA's earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. ABSA International recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, ABSA International kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. ABSA International encourages NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While ABSA supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: ABSA recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

412. Robyn Roberts

I am responding: On behalf of myself

Name: Robyn Roberts

Name of Organization:

Type of Organization: Not Applicable

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): plant pathology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The "One Health" initiative highlights the importance of including all scientific and environmentally-related disciplines to promote human health. It is a major oversight to remove plants from the biosafety protocol. Limiting biosafety guidelines to agents that directly risk "human health" ignores important biological threats to agriculture and the researcher. Specifically:

1. There are many plant pathogens that produce toxins or other agents that adversely affect humans, such as mycotoxins. Examples include aflatoxins produced by Aspergillus species, and deoxynivalenol (DON) produced by Fusarium species, both of which are highly toxic to humans and animals.

2. Releasing genetically modified plants into the environment could result in cross-pollination with agricultural crops or native species, potentially impacting the health of consumers (people, animals), or cause environmental impacts. For example, it could result in population shifts in food sources for pollinators required for agricultural production, and changes in food availability to predators that look toward livestock as secondary food sources.

3. Unintentional release or introduction of pathogens and pests has resulted in many agriculturally significant epidemics that caused food scarcity and/or famine. For example, the Irish Famine (Phytophthora infesans), wheat stem rust (Puccinia graminis), and rice blast (Magnaporthe oryzae).

4. Plant viruses can be easily cloned and introduced to crops. Viruses are a significant threat to agriculture due to the bioterrorism potential, and can be derived completely synthetically. Under the drafted guidelines, a person could order a synthetic virus with gain-of-function potential and accidentally release it through person-to-plant contamination without the proper biosafety guardrails.

5. There are many plant pathogens that are opportunistic human pathogens. All work with pathogens should be evaluated alongside researchers to determine risk of opportunistic infection.

6. It is unclear if plant-hosted insects are included in the “plants” exception. There are many agricultural pests that could cause significant damage to US agriculture, and there are many examples of insects that have been introduced which cause severe agricultural impacts. These include Rocky Mountain Locust (Melanoplus spretus), Boll Weevil (Anthonomus grandis), and the Japanese Beetle (Popillia japonica).

Additionally, the scope of the policy is unclear. The statement that the policy covers “all biomedical research, in laboratory settings, involving biohazards” seems to limit its application to laboratory-based activities. It is unclear whether the policy also applies to field, greenhouse, animal facilities, environmental studies, and other non-laboratory activities involving biological hazards.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): It is unclear what are the definitions of “incident,” “compliance violation,” and “failure to maintain IBC approval.” For example, it is unclear if reporting would be required at any biosafety level for spills remaining within primary containment, a minor event with no exposure or environmental release, or a needlestick involving a sterile needle. Additionally, it is unclear whether “within 24 hours” means clock hours, business hours, or the next business day; whether the incident template is required for events not reportable to NIH; whether required incident information may result in enforcement or funding action. The applicable timelines for institutional posting and NIH responses are also unclear.

3. Continued utility of Risk Groups: Clarification is needed on how institutions should determine risk groups and biosafety levels. The draft does not define risk groups, nor does it have a comprehensive risk-group list like the one that currently exists in the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (NIH Guidelines). The Biosafety in Microbiological and Biomedical Laboratories 6th Edition focuses primarily on biosafety levels and emphasizes project-specific risk assessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The public posting of incident reports, meeting minutes, and NIH responses raises significant privacy, liability, and operational concerns. Detailed reports may allow individuals or laboratories to be identified, especially when combined with information from journal articles and on institutional and government websites. Public disclosure of select-agent activities, high-containment work, principal investigators, and containment failures may also create physical and personnel security risks.

The policy’s public reporting requirement will likely discourage individuals from reporting incidents, potential exposures, and other safety concerns due to concerns about health privacy, retaliation, reputational harm, litigation, or funding consequences. This is the exact opposite of NIH’s intent. Even the best safety cultures will be negatively impacted by this requirement. Incidents reported to the NIH Office of Science Policy will be included in a newly created anonymized database. This effort in and of itself will significantly increase the transparency of biological incidents while encouraging a strong biosafety culture without fear.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The public posting of incident reports, meeting minutes, and NIH responses raises significant privacy, liability, and operational concerns. Detailed reports may allow individuals or laboratories to be identified, especially when combined with information from journal articles and on institutional and government websites. Public

disclosure of select-agent activities, high-containment work, principal investigators, and containment failures may also create physical and personnel security risks.

The policy's public reporting requirement will likely discourage individuals from reporting incidents, potential exposures, and other safety concerns due to concerns about health privacy, retaliation, reputational harm, litigation, or funding consequences. This is the exact opposite of NIH's intent. Even the best safety cultures will be negatively impacted by this requirement. Incidents reported to the NIH Office of Science Policy will be included in a newly created anonymized database. This effort in and of itself will significantly increase the transparency of biological incidents while encouraging a strong biosafety culture without fear.

6. Other feedback relevant to this resource: I am concerned that the best and brightest American scientists, who received their training in the US and have positively impacted human health, will start leaving the US to work in countries that provide better support, clarity, and guidance to researchers while streamlining the process to safely conduct biohazardous work. This will make the US overall less competitive in science innovation compared to other countries, posing a significant risk to national security, technology and intellectual property, and overall influence around the world.

Uploaded File: NIH-Comment-1.pdf

Description: PDF of my comment

Action Items:

1. Create new exemption categories for low-risk research, or, at a minimum, keep current exemptions in place for transgenic animals and certain categories of research. BSL1 and ABSL1 work should have exemption categories if the goal of this policy is to reduce red tape. As written, the red tape actually increases.
2. Change reporting requirements for things that require NIH reports. Low-risk incidents and non-consequential reporting of events would create a safety culture that is counterproductive towards the goal.
3. Add redactions to public facing reports: names, grant numbers, and other identifying information would create unsafe work environments for researchers as well as potentially create conflicts with other privacy laws.
4. Tighten up definitions and scope throughout the policy. Biological agents that cause human disease are the basis for the document, but this is contradicted many times throughout with oversight of BSL1/ABSL1 work.
5. Create a work process where other agency documents and regulations can be used in congruence with or instead of this. This becomes apparent when removing plants specifically but then talking about chemical and radiological mutagenesis.
6. The toxin regulations need to be buttoned up, and the definition shrunk to make the scope more applicable to current risks and foundations of biosafety.
7. There needs to be another draft of this policy for public comment after this first comment period. There are too many things that need clarification that the fear is the final policy after this round of comments may still be unclear and create confusion with implementation.
8. Clear implementation guidance of this policy should be created with concrete examples for many of the agents and functions within.
9. A 6-month implementation timeline is unfeasible, especially at scale and current scope (no exemptions). This would create a burden now, and every 3 years upon protocol renewal.
10. Work with organizations such as CSHEMA and ABSA to refine this policy and open up a new comment period.

This list is not exhaustive. This is a start for the narrative below. These steps, at a minimum, would be needed to feasibly implement anything like this at scale at a large research institution.

A new NIH Policy for Research Involving Biohazards is a welcomed refresh to the NIH Guidelines from over 50 years ago, however, the stated goals of "ensuring that gold-standard science is conducted under gold-standard biosafety" and "removing red tape for low-risk research" seems to be lost in the details of the draft.

The new policy states that its scope will include research involving biological agents, which is defined in the draft as agents that can "cause human disease". The policy goes on to contradict this fact by including review of things that were previously exempt, as well as agents that are worked with at BSL1/ABSL1. I am not sure how this policy can state that it is removing red tape while requiring registration and review of low-risk agents that were previously exempt, as well as stating that the goal is to prevent human disease, when the very definition of BSL1 is that the agents are not disease causing in humans. The mechanism of delegated review is a welcomed process to the IBC; however, this cannot overshadow the fact of the administrative and review burden requiring these "zero risk" activities be approved by the IBC before commencing of work. Along these lines, the reporting requirement to the NIH of a low-risk activity being done without IBC approval leads to an enforcement type atmosphere, rather than a collaborative one, which would be a severe burden on our system.

Additionally, the reporting requirements of this policy will introduce yet another large administrative burden, while actually instilling a culture of non-reporting coming out of the labs. If each incident of zero risk bites/scratches and incidents must be reported to the IBC and then, subsequently, posted on a public facing site, this will cause PIs and labs to not report incidents. This is detrimental to the fundamental way safety should work, as low risk and consequence incidents help inform how processes and procedures work going forward. With the seemingly punitive nature of the new reporting process, many things will not be captured appropriately, and lead to less safety and compliance in the lab. Including PI names, grants, etc will lead to a punitive environment which will lead to less incident reporting. This also has some privacy concerns within the community.

With these reporting requirements, biosafety now feels more like a punitive role, rather than one that strives to help the community with their research. Safety culture is an important part of any organization, especially ours, and with these reporting requirements, this cannot be achieved. PIs will fear to ask for help on any procedures when they think they may be reported to the NIH for any minor "infraction", and incidents will not be reported so that new SOPs can be further developed. Right now, when we walk into a lab space, we are a collaborative group that helps the lab with their projects, but this would lead to them not wanting us in their labs and shutting us out further due to fear and repercussion.

The NIH Policy states that it does not want to interfere with regulations by other entities, so it removes plants from the oversight. However, this is in direct contradiction to itself when it then covers radiological and chemical mutagenesis. These activities are governed under various regulatory and review entities and should not be specifically included in this policy. Toxins are also defined very broadly, as well as confusingly, which leads to contradiction. Toxins are generally chemicals and treated like chemicals when it comes to how they are handled, and therefore the definition should be tightened up to agree with the stated goals of the policy. There are many resources available for toxins, and, if human health is the concern of this policy, information and cutoffs for things like LD50 would be a great place to start when considering toxin safety. Overall, the definition of these remains vague and unhelpful within the policy.

The number of protocols that would come out of the policy being finalized as written is unfeasible to many institutions. Just from the regulation requiring 3 year registrations (we currently are at 5 years) would be a 67% increase in renewal registrations. Also, the zero/low risk protocol number would be unwieldy, if not impossible to review, especially considering a 6-month turnaround with the final policy. Adding the burden of previously exempt and non-human disease-causing materials would be inappropriate and, again, in direct contradiction of the stated goal of the policy.

In conclusion, this policy's aim at reducing red tape and supporting gold standard biosafety misses the mark. The stated goals would be a welcomed change, but the execution of the policy, as written, would fall outside of that end. I believe, minimally, the scope of this policy should be changed where BSL1 and ABSL1 protocols should not need registration, as well as incidents should NOT be posted on a public website. A change in the draft policy would enable institutions to direct their attention and resources to protocols and projects that do have meaningful risk.

Professional associations such as CSHEMA and ABSA have created in depth comments that address many of these high-level comments from above. These organizations should be consulted to revise this draft in detail, and then the community be provided with this draft for additional comment. If gold standard science supported by gold standard biosafety is the goal, working with the community is the only way this can be achieved, and currently, the new policy does not read as that.

Uploaded File: Comment-on-Biosafety-RFI-.docx

I support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards.

We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information,

and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member

may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The unification of oversight for all research involving biohazards, whether or not such research involves recombinant or synthetic nucleic acid technology, is a positive change and one that supports a more comprehensive and cohesive institutional biosafety program. The addition of a Delegated Review mechanism is another positive change, which reduces the burden on IBCs, while providing institutions with the flexibility to define the Delegated Review process in a way that ensures appropriate oversight of lower-risk activities at individual institutions. We support these notable policy improvements.
While many aspects of the draft Policy represent improvements, there are several changes that are likely to have significant negative consequences, as well as points that would benefit from clarification. We respectfully submit the comments below for consideration to further improve the Policy.
• New incident reporting requirements have an expanded scope of what counts as an incident in addition to the requirement to post all incident reports on a public website.
• Impact: These changes are expected to have a significant negative impact. The trust that biosafety programs have built up over the years in supporting researchers and encouraging people to report accidents will be eroded by fear of negative ramifications and/or retaliatory action. Even if reporting is anonymized and only a PI or supervisor name is included in the published report, there is a perceived risk of that information being used against the person, lab, and/or institution. People will be less likely to report accidents, which increases the risks associated with untreated injuries or exposures to hazardous materials.
• Recommendation 1: Individual incident reports should not be publicly posted. Reporting should be to NIH, where data on incidents can be aggregated and trends analyzed and/or reported in a way that removes institutional affiliation to further anonymize individuals involved in an incident. That allows for analysis of the data and identification of trends, which would be a valuable resource to the community, while avoiding negative consequences on the individual, lab, or institution, which would, in turn, undermine the value of the incident reporting process.
• Recommendation 2: If institutions must be required to publicly post incident information, allow an aggregated annual report. Such an approach could be modeled after OSHA's Form 300A (Summary of

Work-Related Injuries and Illnesses). We would strongly recommend this approach for incidents defined by this Policy, which would not be reported to NIH but would be reported to the IBC.
• The draft Policy states that IBC approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required. It further lists failure to maintain IBC approval as a reportable incident.
• Impact: The expected impacts of these changes are a significantly increased administrative burden and unintentional non-compliance. In the absence of a specified term limit, many institutions adopted internal policies that require IBC approval to be renewed within a 5-year period, which also coincides with the length of many grants supporting the approved research activities. Switching to a shorter 3-year renewal cycle presents a significant increase in committee workload. Additionally, well-intentioned PIs may face unexpected emergencies, or their registration renewal may come at a time when they are burdened with high workloads from teaching and/or other institutional responsibilities. Because there is no mechanism described in the draft Policy for allowing extensions to PIs facing extenuating circumstances, failure to renew an IBC registration on time would result in a reportable incident of non-compliance.
• Recommendation 1: Keep a defined term limit on IBC approval but increase the term of IBC approval to 5 years.
• Recommendation 2: Empower IBCs to exercise judgement and flexibility in granting reasonable, one-time extensions to PIs facing extenuating circumstances and/or moving a registration renewal to a different time of year so as not to conflict with other high-workload periods.
• The draft Policy states that research with primary cells that may be contaminated by adventitious agents requires IBC review and approval under Section IV-2. We interpret this new scope to mean that any primary human cell line, tissue, or clinical specimen with an unknown status (has not been tested for bloodborne pathogens or other infectious agents) will have to go to the IBC for approval, whereas none of this material required IBC review previously. Instead, this material fell under the OSHA Bloodborne Pathogens Standard, which requires institutions to establish oversight mechanisms that have worked for many decades.
• Impact: This change is expected to have a significant negative impact. The increased burden on most IBCs will be enormous, with no apparent benefit, since the existing mechanisms to comply with the OSHA Bloodborne Pathogens Standard must still be maintained. This is an unnecessary duplication of oversight, and the increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.
• Recommendation: Allow this type of material to be approved via the new Delegated Review process described in Section IV-3 rather than requiring IBC review. That would allow institutions flexibility to integrate existing biosafety oversight mechanisms into the Delegated Review process defined by the new Policy.
• The draft Policy states that research involving genetically modified cells, viruses, or organisms, other than plants requires IBC approval and approval under Section IV-2. Previously, a large portion of genetically modified cell lines were considered exempt under Section III-F-8, Appendix C-I. For many IBCs, that type of material made up the majority of genetically modified material, and because it was considered exempt and did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely and in accordance with the OSHA Bloodborne Pathogens Standard. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under

Section III-F-8, Appendix C-I now falls under Section IV-2 and requires full committee review.
• Impact: This change is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because the main risk associated with material that fell under Section III-F-8, Appendix C-I was the risk of adventitious agents or bloodborne pathogens, as mentioned in point 3 above. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.
• Recommendation: Retain the Section III-F-8, Appendix C-I exemption, or allow materials that would have fallen under Section III-F-8, Appendix C-I to be approved via the Delegated Review process described in Section IV-3.
• The draft Policy's definition of a genetic modification includes introduction into cells, organisms, or viruses of stable alterations into the genome by passaging. It is not clear what passaging activity falls within the Policy scope. Simply culturing an organism in vitro will lead to accumulation of undefined genetic alterations and could be considered passaging. Cultures that are maintained in a lab are also considered to be passaged through the process of sub-culturing to create multiple stocks from an original sample. Further, most of the time, growing an organism in vitro or in a model system selects for mutations that optimize growth in a lab environment, not in a human host, and these lab-adapted strains typically lose virulence or pathogenicity. The Influenza A/Puerto Rico/8/1934 (H1N1) strain (often called PR8 influenza) is a classic, mouse-adapted laboratory strain of the influenza A virus isolated from a human patient in Puerto Rico in 1934. It is an example of a strain that is a lower risk option for studying influenza. These examples of passaging generally have not required IBC review. In the draft Policy, all of these activities would require IBC review and approval under Section IV-2 (see also point 4 above).
• Impact: The current definition of genetic modification is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because most passaging does not increase the risk of the agent or associated research activities. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.
• Recommendation: We recommend refining the scope of the definition of genetic modifications by defining passaging as the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile. Examples of passaging activities that should be included in Section IV-2 include passaging with the intent or likelihood for an agent to acquire a new virulence trait or antibiotic resistance or to adapt a pathogen to a new host species and/or tissue tropism.
• In the draft Policy, the definition of genetic modification that falls within the scope of the policy now includes modification via chemical or radiological means. Further, the draft Policy requires the IBC to review all genetically modified cells under Section IV-2 (see also point 4 above). The main risk associated with use of chemical or radiological agents to create mutations is in the handling of the chemical or radiological material, not necessarily in handling the cells once the mutagen has been removed. There are separate regulations that apply to chemical and radiological hazards. The use of chemical and radiological hazards is best handled by the respective safety experts who are familiar with the appropriate regulations and safety requirements, not the IBC. Assessment of the risks of these mutagens are outside of the scope of an IBC, since IBC members typically have little to no expertise on chemical or radiological hazards.
• Impact: This is a vast expansion of scope that will duplicate oversight and increase burden on IBCs, without a clear benefit. Further, the IBCs typically lack appropriate expertise for evaluating the risks associated with these mutagens. The increased burden on IBCs will detract attention from higher-risk

matters, which do fall within the expertise of the committee.
• Recommendation: Remove chemical and radiological means from the definition of genetic modifications that fall within the scope of the policy and defer oversight to existing regulations that apply to the use of chemical and radiological hazards. Alternatively, refine the scope to apply to experiments in which the mutagenic agent is combined with the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile, as recommended for passaging in point 5 above.
• The draft policy states that research with genetically modified RG1 biological agents requires Delegated Review under Section IV-3. Previously, most standard cloning and/or protein expression with E. coli and other model host-vector systems were considered exempt under Section III-F-8, and it did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely with proper waste disposal procedures. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8 now requires Delegated Review.
• Impact: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. The increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.
• Recommendation 1: We strongly recommend retaining existing III-F-1 through III-F-8 exemptions.
• Recommendation 2: Furthermore, and supported by decades of safe research experience, we also recommend expanding the exemptions to include other low-risk cloning and protein expression research in model organisms such as E. coli BL21 strains, C. elegans, and Drosophila.
• The draft Policy states that research conducted with transgenic organisms at BSL-1/ABSL-1" requires Delegated Review. Previously, almost all breeding or purchasing of transgenic rodents was exempt under Section III-F-8, Appendix C-VII and was not typically registered with an IBC at all. Instead, oversight of those transgenic rodents typically has been handled through federally mandated Institutional Animal Care and Use Committees (IACUCs) that have biosafety professionals as members who conduct risk assessments and suggest risk mitigation measures as part of that review process. Many IBCs do not even have a mechanism for tracking this information. Additionally, many researchers using transgenic mice are not using any other sort of biological material; the research is often focused on behavioral studies or pre-clinical studies that fall outside the scope of an IBC. A very large proportion of transgenic animal work is done with transgenic rodents and zebrafish, and almost all of that work poses no new risk compared to the unmodified rodents and zebrafish.
• Impact: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. Again, the increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.
• Recommendation 1: We strongly recommend retaining the III-F-8, Appendix C-VII exemption and allow existing oversight of these low-risk animals to continue via the IACUC.
• Recommendation 2: As mentioned in point 7 above, we also recommend expanding the exemptions to include other low-risk transgenic model organisms such as zebrafish, C. elegans and Drosophila.
• The draft Policy defines biological agents that fall within the scope as bacteria, viruses, fungi, or parasites that cause human disease. This definition seems to contradict the draft Policy's requirement for Delegated Review of research with genetically modified RG1 biological agents (see point 7 above). Risk Group 1 agents are not associated with disease in healthy adult humans. Some agents may be considered opportunistic pathogens, but there is currently no list of RG1 organisms that are considered

opportunistic pathogens.
• Recommendation 1: NIH should clarify the nature of biological agents that fall within the scope of the Policy. We recommend that the Policy scope is limited to pathogenic biological agents that cause disease in humans, including opportunistic pathogens but excluding non-pathogenic agents.
• Recommendation 2: As there is no list of RG1 agents, and the list of RG2 agents is incomplete, we further recommend empowering the IBCs, Biosafety programs, and PIs to make the determination of RG1 and RG2 for biological agents that are not currently listed in Appendix B of the NIH Guidelines or the BMBL using the risk assessment guidance provided therein.
• The draft Policy's definition of a genetic modification includes introduction of materials that can be transcribed or translated. This would include materials such as purified or synthetic miRNAs, snRNAs, shRNAs, and mRNAs, which are transient in nature and may lead to changes in gene expression but do not replicate and do not modify or integrate into the genome. Work with such materials was previously exempted under III-F-1 but would now fall under Section IV-2 and require IBC review and approval.
• Impact: The current definition of genetic modification is expected to have a significant negative impact. This will create a significant new burden on IBCs, with no apparent benefit given that no genetic modifications are made with these materials. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.
• Recommendation: We recommend retaining the III-F-1 exemption and removing these materials from the scope of the Policy.
• The scope of the draft Policy includes prions and self-aggregating proteins, and research activities involving these materials would require IBC review and approval. We support the draft Policy as it pertains to prions, but request refinement of the oversight pertaining to self-aggregating proteins. IBC oversight should not extend automatically to every protein capable of self-aggregation. Protein aggregation is common in biology and, by itself, does not establish an infectious or exposure hazard. Oversight should instead focus on proteins or protein assemblies for which there is credible evidence that an aggregated conformer can act as a persistent, self-propagating seed; induce conformational conversion of the corresponding native protein; spread between cells or tissues; and transmit pathology following experimental exposure or inoculation. We recommend the following risk-assessment approach, which is consistent with the BMBL principle that containment decisions should be protocol-driven rather than based only on an agent's name.
• Recommendation 1: Classical mammalian prions and prion-containing tissues should remain categorically within IBC purview because of their established infectivity, potential for serious disease, environmental persistence, and resistance to conventional inactivation procedures.
• Recommendation 2: Seed-competent aggregates of α-synuclein, including preformed fibrils, amplified seeds, and α-synuclein-containing material derived from affected human or animal tissue, should also be subject to IBC review because α-synuclein assemblies have demonstrated prion-like templating, cellular and anatomical propagation, and experimental transmissibility in animal models. Inclusion under IBC oversight should not be understood to mean that α-synuclein is known to be naturally communicable between people or that it presents the same level of hazard as a classical prion.
• Recommendation 3: Other self-aggregating proteins should be evaluated individually rather than be included in Section IV-2 of the draft Policy solely because they form oligomers, fibrils, or amyloid. Relevant considerations should include evidence of experimentally transmissible pathology, persistence of seeding activity, resistance to standard decontamination, source and concentration of the material, route and scale of exposure, use of human- or animal-derived pathological tissue, and procedures

involving inoculation, sharps, aerosols, or other opportunities for occupational exposure. Routine work with non-seed-competent monomeric proteins or aggregates lacking evidence of biological propagation would not ordinarily require specialized biosafety review beyond the requirements otherwise applicable to the experimental system, and we recommend that the Delegated Review mechanism described in Section IV-3 be applied to such work.

• The scope of the draft Policy includes toxins listed as Select Agents, and research activities involving these materials would require IBC review and approval under Section IV-2, while research with biological toxin proteins not on the Select Agent list may be approved by Delegated Review under Section IV-3. We support this overall approach; however, we request refinement of the Policy with the following recommendations.

• Recommendation 1: Allow research activities using exempt amounts of Select Agent toxins to be approved by Delegated Review. Most institutions have already developed effective internal biosafety oversight mechanisms for handling these exempted materials. Integrating those internal oversight mechanisms into the Delegated Review process would allow IBCs to focus on the higher-risk Select Agent work.

• Recommendation 2: Either publish a list of biological toxins that fall within the scope of the Policy or use a threshold toxicity value as a risk-based factor for determining whether a biological toxin requires oversight by the Policy. We further recommend that biological toxins that have an LD_{50} greater than 1000 µg/kg be exempt from this Policy.

• The scope of the draft Policy includes cells, viruses, or organisms, other than plants, that have been genetically modified. It is assumed that animals are included as organisms, but it is not clear what is considered an animal under this Policy.

• Recommendation: Use a definition of animal that is consistent with the Guide for the Care and Use of Laboratory Animals, which has been adopted by the NIH Office of Laboratory Animal Welfare, and which defines animals as any vertebrate animal (i.e., traditional laboratory animals, agricultural animals, wildlife, and aquatic species) produced for or used in research, testing, or teaching.

• The draft Policy indicates that the effective date will be 6 months from publication of final Policy, and that applicability includes ongoing work. It is unclear how ongoing work will be impacted by the new review and approval requirements. Work that was not subject to IBC oversight according to the NIH Guidelines may have been approved via voluntary institutional biosafety oversight mechanisms.

• Impact: Work that was approved by a Biosafety Officer (or other institutional biosafety oversight) and now requires a higher level of review by the IBC would need to cease until IBC approval is obtained. This would have a significant negative impact on a large number of projects that are suddenly subject to new oversight, thereby wasting grant money and setting back important research projects.

• Recommendation: Require activities that have not received approval by a Biosafety Officer or other institutional biosafety oversight mechanism to be reviewed and approved according to the final Policy within 6 months of the publication of the final Policy. For activities that have received approval by a Biosafety Officer or other institutional biosafety oversight mechanism, allow the existing approval to remain in place until such time as de novo registration is required (see point 2 regarding our recommendation to allow 5-year term limits for IBC registration approvals).

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

417. UMass Chan Medical School

I am responding: On behalf of an organization

Name: John Erwin

Name of Organization: UMass Chan Medical School

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: UMass Chan Medical School supports the objective of modernizing biosafety oversight to address genuine and evolving biological risks. However, we are concerned that the proposed definition of "genetic modification" contained in the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112), specifically the provision that classifies introduced nucleic acid molecules as genetic modifications if they "can be transcribed or translated" believe is too broad and could have unintended consequences that run counter to the states objective of the Draft Policy.

This criterion is overly broad, scientifically imprecise, and insufficiently connected to biological risk. The proposed change could substantially expand the scope of biosafety oversight to encompass routine molecular biology, cell biology, and biomedical research that do not produce a meaningful change in the properties or hazards.

Without clear limits, investigators and institutions could be required to interpret a wide range of ordinary experimental materials as "genetic modifications". This ambiguity could result in inconsistent Institutional Biosafety Committee (IBC) determinations, unnecessary administrative burdens, delays in otherwise low-risk research as well as significant confusion in the general public by significantly expanding the definition of "genetic modification."

Such an outcome would be difficult to reconcile with the draft policy's stated objective of calibrating oversight to risk and reducing unnecessary administrative burdens on low-risk research.

Biosafety oversight should be based on demonstrable or reasonably foreseeable hazards and urge NIH to revise this provision before finalizing the policy, replacing a capability-based trigger with a scientifically grounded, clearly defined, and risk-proportionate standard. Such a revision would preserve meaningful biosafety protections while reducing regulatory ambiguity, unnecessary administrative burdens, and avoidable impediments to biomedical research.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

ABSA International — The Association for Biosafety and Biosecurity

Organization:	ABSA International 1200 Allanson Road, Mundelein, IL 60060 Phone: (866) 425-1365 | Email: info@absa.org | Web: www.absa.org
Date:	October 19, 2026
To:	Office of Science Policy National Institutes of Health 6705 Rockledge Drive, Suite 750, Bethesda, MD 20892
Submission Portal:	Submitted via NIH OSP Electronic Comment Portal
Subject / Notice:	Formal Public Comments and Recommendations on the Draft NIH Biosafety Policy for Research Involving Biohazards (Notice Number: NOT-OD-26-112)

ABSA International, the Association for Biosafety and Biosecurity, is a nonprofit professional association representing biosafety and biosecurity professionals in the United States and internationally. Our membership spans academic and research institutions, government laboratories, biotechnology companies, healthcare organizations, public health agencies, and consulting practices. Members bring scientific, technical, operational, and regulatory expertise across diverse biological research and laboratory settings.

ABSA's comments reflect the practical experience of professionals responsible for translating biosafety policy into daily practice. Our members conduct risk assessments, support Institutional Biosafety Committees (IBCs), develop training and containment practices, investigate incidents, and advise institutions on compliance. They understand how policy requirements affect laboratory safety, reporting culture, institutional resources, and the conduct of research.

NIH's commitment to gold standard science provides an opportunity to establish an equally high standard for biosafety oversight. Clear, science-based, and risk-informed requirements can make gold standard biosafety an integral part of rigorous research and reinforce public

confidence in NIH-supported science. ABSA supports NIH's efforts to strengthen biosafety oversight. We offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment while enabling responsible scientific research.

The volume and technical depth of the comments below, together with the significant concerns raised by the broader scientific community, demonstrate that the draft Policy cannot be implemented effectively in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

NIH Form Categories

1. Policy scope, definitions, and gaps of oversight
2. Tiered oversight and calibration to risk, including federal versus local oversight
3. Continued utility of Risk Groups versus Biosafety Levels
4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).
5. Draft Incident Reporting and Meeting Minutes Templates
6. Implementation resources and areas needing additional guidance

CATEGORY 1.0: POLICY SCOPE, DEFINITION OF BIOHAZARDS, AND APPLICABILITY

***Topic to Address**: Appropriateness of the scope of the new policy, including the definition of biohazards, for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.*

Comment 1.1: Policy Section II, Scope - Clarify the scope of the policy.

Title, scope, and intent. The Policy's title suggests a general biosafety framework, but its scope, "biomedical research, in laboratory settings, involving biohazards," ties it to human health under NIH's mission. The title, scope, and stated intent should be consistent.

Scope limitations and One Health. The Policy's scope is limited by an overarching criterion of known or potential risk to human health. It excludes plants from specified genetically modified categories and does not clearly cover hazards affecting only animals, plants, agriculture, or the environment. This narrower scope is difficult to reconcile with the One Health approach, and leaves unclear how NIH will coordinate with the federal programs responsible for those areas. Any resulting gap would fall to other agencies to address. This was a key concern raised in every listening session.

Internal inconsistencies. Despite this human-health scope, several provisions address animal and environmental considerations. Section III-B references agricultural animals and environmental protection. Sections V-A and V-B address the population-level and environmental impacts of GDMOs. The "prion" definition refers to disease "in humans or animals." These provisions do not fit within the scope as written.

Recommendation. NIH should resolve these inconsistencies in one of two ways:

1. **Broaden the scope** to a One Health approach, developed in collaboration with other funding agencies, that ensures adequate oversight of animal, plant, and environmental hazards while minimizing administrative burden; or
2. **Limit the scope explicitly** to hazards to human health, align the title accordingly, and revise the provisions identified above for consistency.

Common 1.2: Clarify the "known or potential risk to human health" threshold for Policy scope

NIH should clarify how the "known or potential risk to human health" threshold in Section II is intended to determine whether research falls within the scope of the Policy. Section II

defines covered research as biomedical laboratory research involving a known or potential risk to human health and one or more specified categories of biohazards. However, Section IV-3 establishes oversight categories for several types of relatively low-risk research, including genetically modified RG1 biological agents, BSL-1/ABSL-1 transgenic organisms, well-characterized cell lines, and certain plasmids and low-risk transgenes. NIH should clarify whether inclusion in one of the enumerated biohazard categories is itself sufficient to establish a "potential risk to human health," or whether institutions must first make a separate determination that the research presents such a risk. If a separate threshold determination is required, NIH should provide criteria and representative examples for making that determination. Clear guidance is needed so institutions can consistently distinguish research that is outside the scope of the Policy from research that falls within scope but qualifies for a lower tier of oversight.

Reference basis: Draft NIH Biosafety Policy for Research Involving Biohazards, Section II (Scope) and Section IV-3.

Comment 1.3: Policy Section II - Clarify how clinical settings fit within the definition of laboratory research [Section II (definition of Laboratory research) and Section V-E.]

Inconsistency. Section II defines laboratory research as research conducted in BSL/ABSL-1 through BSL/ABSL-4 containment facilities, including vivarium, core facilities, and clinical settings. Section V-E, however, acknowledges that clinical research involving the handling and administration of potentially biohazardous materials often occurs in clinical settings that do not conform to laboratory biosafety levels. It is unclear how such settings satisfy the Policy's "laboratory setting" criterion.

Interpretation. We do not read the draft Policy to require IBC oversight of routine clinical or diagnostic activities. For an activity to be covered, it requires biomedical research involving an in-scope biohazard within a laboratory setting.

Recommendation. NIH should:

1. Clarify how a clinical environment that does not conform to a laboratory BSL satisfies the "laboratory setting" scope criterion.

2. Define the boundaries among protocol-required clinical procedures, research specimen processing, research-associated diagnostic testing, standard-of-care testing, and routine patient care.
3. Specify the risk assessment and control framework expected for covered research conducted in non-laboratory clinical settings.

Comment 1.4 - Clarify applicability to downstream clinical sites and products developed with NIH funding

NIH should clarify whether clinical studies involving products developed with NIH funding remain subject to the draft Policy when the subsequent clinical study is not itself NIH-funded.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-C-1-a-(2)*, explicitly cover certain human studies involving materials containing recombinant or synthetic nucleic acids that were developed with NIH funds, when the institution that developed the material sponsors or participates in the subsequent clinical study. The NIH Guidelines also require IBC approval from the clinical trial site before covered human gene-transfer research may begin.

The proposed *NIH Biosafety Policy for Research Involving Biohazards* does not clearly state whether this existing connection to NIH-funded product development will continue. For example, a product could be developed with NIH funding and later evaluated in a clinical study that receives no NIH funding and is conducted at a clinical site that does not otherwise receive NIH funding. It is unclear from the proposed Policy whether that clinical study and clinical site would remain subject to NIH biosafety requirements solely because the product was originally developed with NIH support.

Recommendation. The final Policy should continue the existing approach and say so expressly:

1. **Coverage:** The Policy applies when the institution that developed the product sponsors or participates in the study (including through collaboration or contractual agreements, but not mere provision of materials or licensing).
2. **Responsibility:** That institution must ensure the clinical site obtains IBC approval before the study begins, documented in its site agreement and Biosafety Assurance.
3. **Limit:** NIH funding of the original development does not, by itself, extend the Policy to independent studies at unrelated sites.

Suggested text for Section II: "This Policy also applies to research involving testing in humans of products developed with NIH funds, if the institution that developed those products sponsors or participates in the research. The sponsoring or participating institution is responsible for ensuring that the clinical site obtains IBC review and approval before the research begins."

Rationale. This keeps a rule that already works, places responsibility on the party able to act, and avoids obligations for sites that cannot know a product's funding history.

Related request. Please confirm whether gene-transfer products that do not shed, replicate, or integrate remain subject to IBC review under Section IV-2, since the draft's clinical category is narrower than the Guidelines' human gene transfer definition (Section III-C-1).

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-A-1-a, I-C-1-a-(2), I-C-1-b-(2), and IV-B-1-f. Draft NIH Biosafety Policy, Sections II and IV-2.

Policy Section II, Scope - Clarify oversight related to genetically modified and/or transgenic animals.

Comment 1.5: The definition of "genetic modification" expands scope significantly

The draft definition includes stable genome alterations introduced by passaging, reassortment, chemical means, or radiological means. This breadth creates uncertainty about where genetic modification ends, and the following begin, naturally occurring adaptation, intentional selection, laboratory-induced change, chemical or radiological exposure.

Examples of work that may or may not be covered include serial passage of a virus in cell culture, chemical mutagenesis of animals or cell lines, irradiation, and selection for drug resistance. These changes could require institutions to identify research activities that have not historically been overseen by the IBC. IBCs would need to develop new review processes, expertise, or administrative mechanisms to support compliance.

Comment 1.6: Clarify treatment of low-risk transgenic rodent activities and existing exemptions

Issue. Section II limits the Policy to research involving "known or potential risk to human health." Section IV-3, however, places all research with transgenic organisms at BSL-1/ABSL-

1 in a category requiring prior approval by delegated review, without regard to risk. The draft does not address breeding, purchase, or transfer. The current NIH Guidelines (April 2024) exempt the purchase or transfer of BL1 transgenic rodents (Appendix C-VII) and the breeding of qualifying BL1 transgenic rodents (Appendix C-VIII, adopted at 76 FR 3150). The Guidelines also treat generation of BL1 transgenic rodents under Section III-E-3, which requires registration at initiation but not prior to approval. The draft does not say whether these exemptions continue, so institutions cannot tell whether it is intended as risk-based streamlining, an expansion of review, or both.

Recommendation. The final Policy should apply the Section II threshold to transgenic animal research and adopt the following three tiers:

Tier	Activities	Review
Exempt from the Policy	Breeding, maintenance, cryopreservation, rederivation, transfer, and use of established transgenic animal lines, where the animals can be housed at ABSL-1 and (a) no parental line or expected progeny contains more than one-half of the genome of an exogenous eukaryotic virus from a single viral family, and (b) no transgene is under the control of a functional gammaretroviral long terminal repeat (LTR).	No IBC submission required
Delegated review (Section IV-3)	Generation of new transgenic animal lines at ABSL-1 (e.g., pronuclear injection, CRISPR editing, in vivo delivery of viral vectors) and any change that alters the original risk assessment.	Individual IBC member or subgroup
Full IBC (Section IV-2) or NIH (Section IV-1) review	Activities involving significant biological hazards or uncertainty, including infectious-agent generation or mobilization, hazardous transgene expression, or consequential gene drive activity.	Full IBC; NIH where Section IV-1 applies

Rationale

- **Consistency with the draft's scope.** Most transgenic lines (knockouts, fluorescent reporters, conditional alleles, Cre drivers) present no known or potential risk to human health. Oversight should follow the risk the Policy exists to address.
- **NIH's 2011 finding (76 FR 3150).** NIH concluded that decades of experience showed that breeding BL1 transgenic rodents almost always yields BL1 progeny and poses no appreciable risk to human health or the environment, and that the cumulative

registration burden was not commensurate with that risk. The draft cites no evidence that this conclusion has changed.

- **Burden and focus.** Requiring approval, amendment review, three-year renewal, and public posting of minutes for routine colony work conflicts with the draft's stated aim of removing red tape for low-risk research and diverts IBC attention from higher-risk work.
- **Existing oversight.** IACUC-approved protocols already track animal colonies, and the draft seeks consistency with IACUCs.

Suggested regulatory text (new exemption, or a note to Section IV-3):

> *Breeding, maintenance, transfer, and use of established transgenic animal lines are not subject to this Policy if the animals can be housed at ABSL-1 and (1) neither parental line, nor any expected progeny, contains more than one-half of the genome of an exogenous eukaryotic virus from a single family of viruses, and (2) no transgene is under the control of a functional gammaretroviral long terminal repeat. Generation of new transgenic lines remains subject to Section IV-3.* IBC review classification shall reflect biological hazards and experimental activities, not solely institutional housing containment assignments. Institutions may require additional containment without triggering a higher federal review category.

Request. We ask NIH to adopt this structure in the final Policy or, if it declines, to explain what has changed since 2011 and whether breeding of previously approved lines requires new approval.

Comment 1.7: Clarify oversight of transgenic agricultural and food-producing animals (Policy Sections II and IV-3)

The draft Policy does not clearly distinguish transgenic laboratory animals from transgenic agricultural or food-producing animals. Applying the same oversight approach to both groups may overlook material differences in potential consequences. Genetic modifications in agricultural animals may have implications beyond the individual research animal, including animal health, breeding populations, food production, environmental release, and interactions with other agricultural or ecological systems.

The Policy should therefore specifically address transgenic agricultural and food-producing animals and clarify how the Section II threshold of "known or potential risk to human health" applies when relevant risks may arise indirectly through animal health, agriculture, food systems, or environmental pathways.

Summary of recommendation. We recommend that the final Policy (1) distinguish transgenic agricultural and food-producing animals from routine transgenic laboratory rodent activities, (2) require an institutional biosafety risk assessment for the creation and use of transgenic agricultural animals, including consideration of animal, agricultural, environmental, and food-system consequences where applicable, and (3) establish risk-proportionate review pathways based on the nature of the genetic modification and the credible consequences of release, reproduction, or entry into agricultural systems.

This requirement should apply to animals whose genomes meet the draft Policy definition of a transgenic animal. Administration of DNA, RNA, recombinant or synthetic nucleic acids, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal should not, by itself, cause the animal to be classified as transgenic. Such research should instead be evaluated based on the properties and risks of the administered material and the experimental activity.

Rationale.

- *Agricultural animals present risk pathways not ordinarily associated with laboratory rodent colonies.* Agricultural animals may enter breeding populations, interact with conventional livestock, enter or affect food-production systems, or be maintained in environments where containment differs substantially from traditional laboratory animal facilities. These pathways should be considered when determining the appropriate level of oversight.

- *Human health cannot be considered independently of animal, agricultural, and environmental health.* A modification that presents little direct occupational risk may nevertheless have potential consequences through animal disease, food production, environmental release, or effects on agricultural populations. A biosafety framework should recognize these interconnected pathways rather than limiting assessment to direct laboratory exposure.

- *Oversight should focus on the genetic modification and its credible consequences.* The mere presence of administered DNA or RNA should not make an animal transgenic. The relevant distinction is whether the animal itself has undergone a stable genomic modification and whether that modification creates a credible biosafety, agricultural, environmental, animal-health, or food-system consequence.

- *Existing animal-use oversight does not replace biosafety review.* IACUC review addresses animal care and use but does not necessarily evaluate the full range of biosafety, environmental, agricultural, food-chain, or population-level consequences associated with a transgenic agricultural animal. Where those risks exist, biosafety review provides a distinct function.

- *Oversight should be coordinated across applicable authorities.* Transgenic agricultural animal research may fall within the jurisdiction or expertise of multiple federal agencies. NIH should clarify how its institutional biosafety requirements interface with USDA, FDA, and other applicable federal authorities so that responsibilities are clear and duplicative review is minimized.

Proposed oversight structure.

1. **Institutional biosafety risk assessment:** Creation or use of a transgenic agricultural or food-producing animal should undergo an institutional biosafety risk assessment that considers, as applicable:

    a. the nature and stability of the genomic modification;

    b. whether the modification is heritable and the potential for transmission through breeding;

    c. effects on animal health, phenotype, host range, susceptibility, or disease;

    d. potential entry into breeding or food-production systems;

    e. potential environmental release or interaction with non-research animal populations;

    f. whether the modification involves sequences derived from RG2 or higher agents, toxins, gene drive systems, or other genetic elements with elevated risk; and

    g. applicable federal, state, or other regulatory oversight.

2. **Delegated review under Section IV-3:** Transgenic agricultural animal research may be eligible for delegated review when the institutional risk assessment demonstrates low biosafety risk, the animal can be maintained under appropriate ABSL-1 or equivalent agricultural containment conditions, and there are no credible elevated animal-health, environmental, agricultural, or food-system consequences.

3. **Full IBC review under Section IV-2:** Full IBC review should apply when the modification presents credible higher-consequence risks, including potential effects on animal health or agricultural populations, environmental establishment, food or breeding systems, or when containment above ABSL-1 or equivalent agricultural containment is warranted.

4. **NIH or other federal review, as applicable:** Research presenting risks within the jurisdiction of NIH or another federal agency should follow the applicable federal review pathway. NIH should identify when another agency's review may satisfy or substitute for specific NIH requirements and which institutional biosafety responsibilities remain.

Proposed regulatory text. NIH should add the following clarification to Section IV-3:

Transgenic agricultural and food-producing animals. Research involving transgenic agricultural or food-producing animals shall undergo an institutional biosafety risk assessment before initiation. The level of IBC review shall be commensurate with the nature of the genetic modification and the potential consequences to human or animal health, agriculture, food systems, or the environment. An animal shall not be considered transgenic solely because it is administered DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material that does not integrate into the animal's genome and is not capable of autonomous replication or stable maintenance within the animal.

Request. We request NIH to distinguish transgenic agricultural and food-producing animals from routine low-risk laboratory rodent activities and establish a risk-based review framework that accounts for the additional animal-health, agricultural, environmental, and food-system consequences that may arise from stable genetic modification of these animals.

Comment 1.8: Define the coverage of recombinant and synthetic nucleic acids

In Policy Sections II and IV, NIH should clarify the status of standalone recombinant or synthetic nucleic acid research under the draft Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B and III-F, explicitly define recombinant and synthetic nucleic acid molecules and establish exemptions for certain standalone nucleic acids, including specified molecules that are not contained within organisms, cells, or viruses.

The proposed NIH Biosafety Policy instead defines scope primarily through biological agents and genetically modified cells, viruses, and organisms and does not explicitly state how standalone recombinant or synthetic nucleic acids are treated, while Section IV-3 separately identifies certain plasmid research as eligible for delegated review. NIH should clarify

whether standalone nucleic acids are intentionally outside the scope of the new Policy and, if not, identify the circumstances under which they become covered and the applicable oversight category. Explicit clarification would help institutions distinguish intentional risk-based streamlining from an unintended gap in scope.

Reference basis: NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-B, III-F-1, and III-F-2. Draft NIH Biosafety Policy, Sections II, IV-3, and V-C.

Section II, Definitions

Comment 1.9: Policy

- The draft policy uses the term "**biological agent**," which is closely associated with biological weapons, notably in 18 U.S.C. § 178 and the Biological Weapons Convention. Although the term also appears in the Select Agent regulations (42 CFR Part 73), the Policy's scope extends well beyond select agents. We recommend replacing "biological agent" with "infectious microorganism or biological material," consistent with *Biosafety in Microbiological and Biomedical Laboratories* (BMBL). This would align the Policy with established biosafety terminology, and the risk assessment framework institutions already use, without implying a weapons or security context.

- The draft policy uses the term "**adventitious agents**" in three places without defining it: Section IV-2, which requires IBC approval before initiation for research with "primary cells that may be contaminated by adventitious agents"; Section V-A, which says primary cells and tissues may harbor them; and the incident reporting provisions, which exempt post-exposure treatment given for the potential presence of adventitious agents from NIH reporting unless a laboratory-acquired infection results. Without a definition, it is unclear whether work with such materials is within scope under Section II, and read literally, "may be contaminated" could sweep in nearly all primary cell work, including cells from low-risk sources, which conflicts with Section IV-3's delegated review of well-characterized cell lines. It also leaves institutions unable to apply the reporting exception consistently.

  We recommend that NIH remove the requirement or (1) define the term, for example as an unintended biological agent present in cells, tissues, animals, or reagents that was not

deliberately introduced and is not part of the planned research; (2) replace "may be contaminated" in Section IV-2 with risk-based criteria tied to the source and screening status of the material (for example, unscreened primary human or non-human primate cells), so that lower-risk primary cells fall under Section IV-3 or outside the Policy; and (3) clarify how the term relates to the Section II scope and the incident reporting exception, referencing existing BMBL and OSHA bloodborne pathogen guidance rather than creating new standards.

- The phrase "**potential risk to human health**" is undefined and ambiguous. As written, it could encompass hazards unrelated to biological materials, such as chemical, radiological, physical, or ergonomic hazards, which are already regulated by other federal agencies, including OSHA, EPA, and NRC. We do not believe NIH intends to extend the Policy to these hazards. The draft also does not specify who determines whether the threshold is met or what standard applies. We recommend that NIH:

    a. Define "potential risk to human health" as the potential to cause human disease or adverse health effects arising from the infectious microorganisms or biological materials within the Policy's scope.

    b. State explicitly that the Policy does not address non-biological hazards.

    c. Specify who determines whether the threshold is met (e.g., the Institutional Biosafety Committee) and the standard to apply, such as a risk assessment consistent with BMBL.

- The draft policy does not define "**Transgenic animal**." We recommend that NIH provide a definition and clarify that administering DNA, RNA, recombinant or synthetic nucleic acid molecules, or other genetic material does not by itself make an animal transgenic, provided the material does not integrate into the animal's genome and is incapable of autonomous replication or stable maintenance. We suggest the following:

    Transgenic animal: An animal whose genome has been intentionally modified through the introduction, deletion, replacement, or alteration of genetic material, such that the modification is stably incorporated into the animal's genome or germline and maintained through cellular replication, regardless of whether it is heritable by offspring.

- The proposed definition of "**prion,**" as *misfolded forms of proteins that can self-propagate and cause neurodegenerative disease in humans or animals,* is inconsistent with the Policy's scope. It references neurodegenerative disease "in humans or animals," whereas

the Policy is limited to risks to human disease. This would expand coverage to prion diseases of animals while excluding animal diseases caused by other etiologic agents. We recommend that NIH revise the definition to align with the Policy's scope, or address animal disease consistently across all agent types.

- The proposed definition of "**Toxins**" should include only those of living biological origin (plants, bacteria, fungi, viruses, etc.). This term does not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (aka "sensitizers").

- Define **"peptide"** as a molecule consisting of two or more amino acids linked by peptide bonds, generally shorter than 50 amino acids and capable of having biological activity depending on its sequence, structure, concentration, and context.

- Retain reassortment and non-transgenic methods within the "**genetic modification"** definition. Clarify whether incidental genomic changes from routine passaging are included or whether the definition applies to deliberate genetic alterations. Address how this distinction applies to reverse genetics and viral rescue systems, including recovery of wild-type organisms, and provide examples distinguishing routine maintenance from intentional modification.

- Define "**gene drive modified organisms"** and the acronym of GDMO consistently with the existing definitions of gene drive and genetic modification. This will help institutions apply the associated membership, containment, and review requirements consistently.

- Define "**shedding**" for purposes of determining IBC oversight of clinical research and clarify whether the term refers to release of biologically active or potentially transmissible material rather than detection of nonviable material or nucleic acid alone. Section IV-2 requires full IBC review for clinical research involving products capable of "shedding, replicating, or integrating," and Section III-B identifies shedding as a biosafety consideration for research involving human participants. However, the Policy does not define shedding or establish the characteristics that make shedding relevant to biosafety risk. FDA's Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products defines shedding as release of the administered product from a patient and distinguishes shedding from biodistribution; the guidance also frames transmission concerns around release of intact virus or bacteria rather than degradation products such as nucleic acid fragments. NIH should define "shedding" for purposes of this Policy, consider harmonization with relevant FDA terminology where appropriate,

and clarify whether detection of noninfectious or non-biologically active material alone is sufficient to place a clinical study within the full-IBC-review category.

Reference basis: Draft NIH Biosafety Policy, Sections III-B and IV-2. U.S. Food and Drug Administration, Design and Analysis of Shedding Studies for Virus or Bacteria-Based Gene Therapy and Oncolytic Products: Guidance for Industry (August 2015).

- Use of "**Universal Precautions**" in clinical research settings. The draft states "*However, precautions to protect personnel must include the use of universal precautions such as gloves, and eye and respiratory protection.*" We recommend revising the sentence to use current, risk-based infection-prevention terminology (*Standard Precautions*) and to clarify that the selection of PPE must reflect the hazards associated with the research materials and procedures being performed.

Section II: Gaps of Oversight

Comment 1.10: Biosafety Officer: Designation, Qualifications, Standing, and Institutional Capacity

Policy Sections III-A; III-B (IBC Membership; Biological Safety Officer); Biosafety Assurance

ABSA International believes the draft Policy misses an important opportunity to support the biorisk management field. It fails to describe the qualifications of a biosafety/biorisk professional; furthermore, it omits details outlining their role, standing, and the critical institutional support needed to ensure the Biological Safety Officer (BSO) can effectively execute their duties. In our March 2026 response, ABSA International requested that NIH clearly define the requirements, roles, and responsibilities of a BSO as it relates to this proposed policy implementation and IBC oversight; however, the current draft is still lacking these vital details. As currently written, the policy only lists four (4) duties and ties the NIH's requirement for a BSO exclusively to the presence of BSL-3/BSL-4 laboratory or gene drive research and allows institutions without a BSO to assign "another official" for which no minimum qualifications are outlined.

As this vital component was omitted from the original draft, ABSA International welcomes the opportunity to collaboratively define the minimum qualifications that would allow an institution to meet any modernized biosafety policy.

Designation. ABSA International does not support limiting the BSO requirement to institutions that only conduct research at BSL-3, BSL-4, or with gene drive modified organisms. While the draft greatly expands the Policy's scope to include wild-type agents, genetically modified cells and organisms, toxins, prions, and clinical research, it fails to consider that a vast majority of this type of work occurs at BSL-2; therefore, leaving a large oversight gap. Additionally, this policy presents a very narrow scope of oversight which eliminates the requirement to assess risks associated with animal, plant, and arthropod associated pathogens. ABSA International recommends that NIH base the BSO requirement off each institution's research portfolio and risk profile, not exclusively on the three (3) aforementioned qualifiers.

The draft policy also adds additional regulatory burden on the BSO, their designee, and any associated staff by requiring substantial work including:

- Periodic inspections
- Incident response and investigation
- 24-hour notification
- 30-day reporting to NIH
- Delegated review
- Technical advice
- Petitions to NIH
- Enhanced reporting of IBC minutes

Minimum qualifications. Where a BSO is required, the NIH should define minimum qualifications and outline the need for direct access to leadership/authority to support the identification and escalation of unresolved risks. In that light, ABSA International recommends a broad statement of qualifications rather than a mandatory degree or credential. This approach is consistent with ABSA's earlier position that such mandates would create unnecessary barriers to entry and potentially disqualify highly qualified personnel. Please consider the below proposed language:

The BSO shall be qualified through a combination of education, training, and experience commensurate with the biohazards, containment levels, and complexity of the institution's research. Qualifications should generally include:

- *Education in the biological or physical sciences, with knowledge of microbiology and molecular biology;*

- *demonstrated competence in biological risk assessment and risk mitigation, including containment practices, safety equipment, and facility design and operation;*
- *working knowledge of the Policy, the BMBL, and other applicable federal, state, and local requirements (e.g., the Federal Select Agent Program, import permits, and transport of biological materials) as applicable to their institution; and*
- *the ability to train, advise, investigate incidents, and communicate effectively with researchers, IBC members, regulatory agencies (as applicable), and institutional leadership.*

Institutions supporting BSL-3/ABSL-3, BSL-4/ABSL-4, gene drive research, or research subject to dangerous gain-of-function (DGOF) or international research of concern (IROC) oversight should ensure the BSO has demonstrated experience with those activities. Professional credentials, such as the Registered Biosafety Professional (RBP) and Certified Biological Safety Professional (CBSP), are recognized evidence of competence and are preferred, but are not required. Furthermore, institutions must provide ongoing support to the BSO's continuing professional development ultimately supporting institutional alignment with current guidance and regulations.

Institutional standing, access, and authority. The BSO's role should be that of a critical institutional official and should be comparable to that of an Attending Veterinarian regarding the authority to halt operations if prescribed procedures and practices are not adhered to. ABSA International recommends that each institution describe the following in its institutional plans/policies:

1. The BSO's reporting line has direct access to the Institutional Official and senior leadership;
2. access to all research spaces and records subject to the Policy;
3. authority to identify and escalate unresolved risks to the IBC and institutional leadership;
4. independence from the research units of which the BSO oversees, with protection from retaliation for good-faith safety determinations; and
5. staffing, resources, and funding for training, professional development, and credential maintenance that are in alignment with the research portfolio and risk profile.

Roles and responsibilities. The Policy should describe the BSO's role as a professional who administers or leads the institutional biosafety program and not merely focus on their role

as an inspector. In addition to the duties outlined in the Policy, the BSO's responsibilities should also include:

- Supporting PIs and the IBC with risk assessments and protocol pre-reviews;
- Serving as a voting IBC member and, where permitted, as a designated or delegated reviewer;
- Developing and delivering biosafety and biosecurity training;
- Leading or coordinating incident response activities, investigations, root cause analysis, verification of corrective actions, and NIH reporting;
- Assist with developing emergency response plans;
- Coordinating with occupational health on medical surveillance and post-exposure response;
- Advising on biosecurity, inventory, and material transfer;
- Preparing or assisting with NIH containment petitions; and Supporting the institution's DGOF and IROC determinations and coordinating with its institutional review mechanism and designated institutional contact.

Operational duties may be assigned to qualified staff at the discretion of the BSO.

Officials assigned BSO responsibilities. For institutions not required to appoint a BSO, the draft permits another institutional employee to assume the BSO responsibilities. It is strongly recommended that guidance be established to define the minimum qualifications that an individual must possess. Conversely, where the NIH requires a BSO, institutional plans/policies should recognize that position as a distinct institutional authority, not simply another administrative assignment.

Staffing and expertise. The proposed Policy will affect institutions disproportionately, as entities that have not previously staffed a BSO position/biosafety office will need support and guidance on how to do so effectively. Institutions conducting high containment, high volume, or technically diverse research may need additional biosafety professionals, IBC administrative support, and IT/security capacity to appropriately manage the increased workload. Institutional plans/policies should therefore scale expectations to each institution's research portfolio.

NIH should consider the financial burden placed on institutions to meet the Policy requirements due to the potential anticipated need for additional specialized staff.

Due to anticipated increased workload and potential need for additional funding and staffing, ABSA International kindly requests that the NIH provide FTE estimates so that the financial burden associated with compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101) can be communicated to the greater biosafety community and their leadership.

Defining these expectations would set support and funding standards comparable to those for IRBs and IACUCs. It would also give institutional leadership a clear basis for planning and funding compliance with both this Policy and the USG Policy for Stopping High-Risk Life Sciences Research (NOT-OD-26-101). Under both policies, the BSO is often the institution's primary resource of risk assessment expertise. We recommend that the NIH implementation resources include a model BSO role description and associated competency guidance, developed in coordination with the biosafety professional community. This guidance could take the form of a matrix that scales expectations to institutional size and complexity.

Ultimately, the effectiveness of a modernized NIH biosafety policy depends not only on clearly defined requirements, but also on ensuring that institutions have qualified professionals, authority, and resources necessary to implement them. The BSO is central to translating policy into effective institutional practices, identifying and mitigating risks, and supporting a culture of safety that protects researchers, the public, the environment and the research enterprise. Expectations for this role must therefore be matched by appropriate institutional support and a realistic understanding of the staffing, expertise, and funding required for compliance. ABSA International encourages NIH to work collaboratively with the biosafety professional community to develop clear, scalable implementation guidance that reflects the diversity and complexity of institutional research programs. Establishing these expectations will help ensure that the revised Policy achieves its intended goals while supporting consistent, effective, and sustainable biosafety oversight across the research community.

Comment 1.11: Clarify the rationale and transition plan for removal of genetically modified plants and certain plant pathogens.

NIH should clarify the rationale and transition plan for removing plants, including genetically modified plants, from the scope of the new Policy. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024) currently establish IBC

oversight and containment requirements for specified research involving genetically modified plants, including provisions addressing plant containment and potential environmental impacts. In contrast, Section II of the proposed NIH Biosafety Policy excludes plants from the covered categories of genetically modified cells and organisms, and NIH's August 2026 Table of Changes expressly states that genetically modified plants and plant pathogens that do not cause human disease will not be covered. NIH should clarify the policy with the Table of Changes and clarify the rationale for this change, how institutions should transition research currently overseen under the April 2024 NIH Guidelines, and what oversight NIH expects for contained plant research presenting biosafety or environmental risks when no other Federal requirement applies. This clarification would help institutions distinguish an intentional change in NIH jurisdiction from activities for which continued institutional biosafety oversight may remain appropriate.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections III-D-5 and III-E-2 and associated plant-containment provisions. NIH Office of Science Policy, Table of Changes from the Current NIH Guidelines to the Draft NIH Policy for Research Involving Biohazards (August 2026).

CATEGORY 2: TIERED OVERSIGHT AND CALIBRATION TO RISK, INCLUDING FEDERAL VS LOCAL OVERSIGHT

Comment 2.0 - Clarify when oversight by another Federal agency substitutes for NIH or IBC oversight

Section II of the proposed *NIH Biosafety Policy for Research Involving Biohazards* states that research subject to the Policy that is also under the regulation or purview of another Federal agency may proceed under that agency's oversight once applicable approvals or clearances have been obtained.

The *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1*, contain a similar provision, but it is more specific: approval by another Federal agency with jurisdiction can substitute for NIH review or approval. It does not state that required institutional IBC oversight is also eliminated.

The broader wording in the proposed Policy could therefore be interpreted to mean that another Federal agency's oversight may replace not only NIH review, but potentially institutional requirements such as IBC review and approval.

NIH should clarify whether this provision is intended only to avoid duplicative Federal review or whether oversight by another Federal agency can also satisfy institutional IBC requirements. NIH should also identify which Policy requirements, such as IBC review, institutional biosafety oversight, incident reporting, and what other requirements remain applicable when another Federal agency has jurisdiction over the research.

Reference basis: Draft NIH Biosafety Policy, Section II. NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section I-A-1.

Comment 2.1 - Clarify the institutional boundaries of the expanded applicability to non-NIH-funded research

NIH should clarify the institutional boundaries and implementation requirements associated with extending the Policy to non-NIH-funded research at institutions receiving NIH funding. Under the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2, the institutional trigger is NIH support for recombinant or synthetic nucleic acid research; once triggered, covered recombinant or synthetic nucleic acid research conducted at or sponsored by that institution is subject to the NIH Guidelines regardless of funding source. The proposed NIH Biosafety Policy materially broadens this by applying the Policy to covered non-NIH-funded biomedical research conducted at an institution that receives any NIH funding, irrespective of whether

that NIH funding supports research involving biohazards. NIH should clarify how "institution" and "sponsored by the institution" should be interpreted, particularly for organizations with multiple campuses, separately incorporated hospitals or research entities, affiliates, subsidiaries, shared IBC arrangements, contract research organizations, and research conducted at external sites. NIH should also clarify responsibility where more than one institution conducts or sponsors covered research. Clear organizational criteria will be important to ensure that institutions can identify all research subject to the Policy and avoid inconsistent interpretations across complex research organizations.

Reference basis: Draft NIH Biosafety Policy, Section II (Scope; Compliance and Enforcement). NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Sections I-C-1-a-(1) and I-D-2.

CATEGORY 3 ADDRESSING: CONTINUED UTILITY OF RISK GROUPS (RGs) AS A BASELINE FOR RISK ASSESSMENT, PARTICULARLY WHEN AGENTS ARE BEING GENETICALLY MODIFIED, VERSUS USE OF BIOSAFETY LEVEL (BSL) OUTLINED IN THE BIOSAFETY IN MICROBIOLOGICAL AND BIOMEDICAL LABORATORIES (BMBL).

Comment 3.0: Risk Groups should not serve as a classification that drives laboratory oversight

NIH asked about the continued utility of RGs as a baseline for risk assessment, particularly for genetically modified agents. We recommend that NIH remove RG "classifications" as a basis for oversight or redefine them as an informational reference only.

Why RGs are poorly suited to laboratory use:

- **They describe risk to healthy adults in the community.** Section V-A says RGs reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a coworker is healthy, and some individuals are more susceptible because of medications, immune status, or pregnancy.
- **They reflect community exposure, not laboratory conditions.** Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the community or environment.
- **They have no baseline for novel constructs.** Recombinant and synthetic nucleic acid work does not exist in the community until it has been studied in the laboratory, which is the purpose of the laboratory.
- **They cover only human etiologic agents.** The Policy's definition of biohazards is broader than agents that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
- **They are misinterpreted.** Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory personnel and for the environment outside the laboratory.

Recommendation: Retain the RG list, if at all, as one input to the first step of risk assessment (characterizing the hazard). Oversight categories in Section IV and containment decisions should rest on experiment-specific risk assessment and the BSL/ABSL framework. Section IV currently keys several categories to RGs (IV-1 through IV-3), and these should be revised accordingly.

Comment 3.1: The draft policy conflates RG classification with biocontainment level

The "IBC Functions" section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents "for which the RG classification or containment level is not available in the BMBL," and says the IBC may not approve such research "until authorized by NIH and any other applicable Federal, State, or local entities."

1. **The terms are not interchangeable.** Section V-E of the draft states that RGs and BSLs are related but not equivalent. The IBC Functions text nonetheless treats "RG classification" and "containment level" as alternative things that might appear in the BMBL. We ask NIH to use the terms consistently throughout.
2. **The BMBL does not assign RGs.** It provides agent summary statements with BSL recommendations. A condition referring to an RG classification "in the BMBL" cannot be met.
3. **The role of "and any other applicable Federal, State, or local entities" is unclear.** NIH should specify which entities this refers to, whether their approvals are sequential or concurrent, how they are coordinated, and what happens if determinations conflict.
4. **The scope of the petition requirement is unclear.** As written, the requirement may continue to apply to genetically modified non-pathogens and RG1 agents that are not specifically listed in the BMBL. NIH should state whether that is intended.
5. **Determinations should be published and reusable.** Section III-D commits NIH to publish approved determinations for lowering containment of RG3 and RG4 agents. It makes no equivalent commitment for emerging, novel, or zoonotic agents. We ask NIH to publish all containment determinations (agent, modification, determined containment, and rationale) in a searchable public resource that other institutions and investigators may rely on. This would avoid repeated petitions for the same agent and modification and reduce administrative burden. NIH should also set a target timeline for responding to petitions, since the draft says only "timely."

CATEGORY 4 ADDRESSING: MECHANISMS TO ENCOURAGE AND ACCOMODATE VOLUNTARY COMPLIANCE FOR RESEARCH NOT SUBJECT TO THE POLICY (e.g., AT NON-NIH FUNDED INSTITUTIONS).

No comment at this time.

CATEGORY 5 ADDRESSING: DRAFT INCIDENT REPORTING AND MEETING MINUTES TEMPLATES

Comment 5.1: Consider risk-proportionate public disclosure of biosafety incident reports and PI identification

NIH should reconsider whether identifiable public disclosure requirements are appropriate for all biosafety incidents subject to the Policy and clarify what information is necessary to achieve meaningful public transparency. Section III-B requires institutions to post all incident reports on a public-facing institutional website, including reports of lower-risk incidents that are managed institutionally and are not required to be reported to NIH. The Draft NIH Incident Reporting Template also requires identification of the Principal Investigator (PI) and does not permit redaction of the PI's name, as NIH excludes the PI from the exemption allowing individuals involved in an incident to remain unidentified. The stated rationale is that information already widely available from public sources, including PI names, biological agents, and grant numbers, may not be redacted. While ABSA supports appropriate transparency regarding significant biosafety incidents and institutional responses, we strongly urge NIH to carefully calibrate disclosure requirements to the significance and potential public health consequences of each incident. For lower-risk incidents that do not meet NIH reporting thresholds, de-identified reports, standardized summaries, or aggregated reporting may provide meaningful transparency and opportunities for community learning. NIH should also clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports and consider whether such identification is necessary when it does not materially contribute to understanding or preventing these incidents.

Reference basis: Draft NIH Biosafety Policy, Sections III-A and III-B. Draft NIH Incident Reporting Template (August 2026), "Redaction and Posting of Incident Reports" and Part 1.

Comment 5.2: Limit public content to information that supports transparency

NIH should not require routine public disclosure of:

1. Investigator's names
2. Grant numbers or internal project numbers
3. Sensitive animal research information
4. Select agent and toxin information
5. Proprietary materials and research outcomes

6. Identifying facility information
7. Other details that could compromise safety, security, or personnel protection

Personnel safety. In some areas of research, particularly animal research and other activities that have historically attracted harassment, threats, or targeting of researchers, public disclosure of investigator identities, funding information, or other identifying details may create risks to researchers and animal care personnel without a corresponding transparency benefit. These concerns also apply to information requested in the Biosafety Assurance statement, including continuously updated IBC rosters and contact information for IBC chairs, Biological Safety Officers, IBC contacts, and other individuals whose information is expected to be linked to the statement.

Research security. Publicly posted IBC meeting minutes could enable the aggregation of valuable intellectual property and research information over time and across institutions throughout the United States. Taken together, these records could reveal the biological agents institutions work with, the direction of unpublished research proposed by individual laboratories, the locations of high-containment research, and the number of facilities experiencing failures involving equipment, personnel training, standard operating procedures, or other safeguards. This information would be available to anyone, including foreign adversaries and other malicious actors. Such unprecedented access stands in stark contrast to federal research security policies and the Federal Select Agent Program's biosecurity measures and restrictions on security-sensitive information. We ask NIH to coordinate with federal research security and select agent authorities, including the Office of Science and Technology Policy, when establishing public disclosure requirements.

Alternative. NIH can meet its transparency goal by publishing aggregated, deidentified incident data through an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center. Full records should remain available to NIH and other authorized reviewers to support investigations of laboratory-acquired infections (LAIs) and other public health efforts.

Comment 5.3: Require content elements, not a rigid template

Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based

approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

Comment 5.4: Distinguish federal and state requirements

NIH should replace the term "appropriate and allowable" redactions with "specific and allowed" redactions that follow a set of standardized examples that allow the institutions to withhold information that poses a safety or security risk. State public-records laws vary and may affect what information institutions can redact. NIH guidance should distinguish between required federal posting and redaction standards from any additional disclosure and disclosure obligations imposed by applicable state laws.

Comment 5.5: Align reporting requirements with proportionate risk mitigation measures

The draft reporting requirements rely on ambiguous phrases such as "any incident," "loss of containment," "significant problems," and "minor spills... generally do not need to be reported," and fail to account for established engineering controls across biosafety levels. As currently written, the requirement to report "potential releases involving facility and/or equipment failures even when redundant systems were functioning properly" would treat a fully mitigated spill inside a biosafety cabinet as a reportable incident, without recognizing how containment engineering actively protects personnel and the environment (see table below). When redundant systems function properly and maintain containment, a facility or equipment component failure does not, by itself, result in a biological material release. In such a scenario, failure alone does not establish a potential release. This reporting requirement is therefore internally contradictory because it characterizes a failure as a potential release even when functioning redundant systems maintain containment and prevent a release. NIH should remove this phrasing from the Policy.

Comparative Containment Risk Profile: BSL-3 vs. BSL-4

Biosafety Level	Engineering Barrier Architecture	Incident Risk & Containment Impact
BSL-3 / ABSL-3	Primary containment (BSC/sealed cup) combined with directional negative airflow	A spill outside a BSC is considered a breach of primary containment, requiring room evacuation and air

	and 100% exhaust, and at times through HEPA filtration.	clearance. Directional airflow prevents room escape.
BSL-4 / ABSL-4 (Suit Lab)	Maximum containment: positive-pressure suits, air pressure resistant (APR) doors, airlocks with chemical showers, pass-through autoclaves, effluent treatment systems.	A spill outside a BSC is considered a breach of primary containment, however, personnel are fully encapsulated inside positive-pressure suits, eliminating the potential risk of exposure. Secondary/tertiary barriers actively prevent environmental release. Due to the type of personnel protective equipment used in the laboratory, room evacuation is not required. Both supply and exhaust air are HEPA filtered and additionally, APR doors prevent room escapes.

Proposed Recommendation: Four Calibration Rules for Section III-B

1. **Anchor 'Release' to Containment Boundaries:** Release means a failure in biosafety practice and/or equipment such that there is an escape of biological material beyond the defined biocontainment boundary.
2. **Calibrate by Biosafety Level:** Acknowledge that higher containment levels (BSL-4) possess redundant secondary envelopes that prevent environmental dissemination even during procedural disruptions.
3. **Define 'Exposures' and 'Medical Treatment':** Clarify that PPE/equipment failures in BSL-3/4 without active agent exposure are not reportable incidents. Align 'medical treatment' explicitly with OSHA standards (care beyond basic first aid).
4. **Eliminate Subjective Phrasing:** Remove vague terms like 'generally' in minor spill rules, and define 'significant violations' as non-compliance directly compromising containment or involving unapproved high-consequence research.

Appendix: Proposed Regulatory Text Amendments

To operationalize these recommendations, we propose the following specific amendments in the final policy:

Section II. General Definitions — Insert New Definition:

- **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.

- **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.

Category 6: Feedback on the implementation resources and areas in which additional guidance would be beneficial.

Comment 6.0: Provide risk assessment guidance for self-aggregating proteins

Policy Sections II and V-A

The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.

Comment 6.1: Clarify oversight of computational and AI assisted work

Policy Sections II and V-C

Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.

Comment 6.2: ABSA recommends the Retention in the Policy

Make BSL-3 enhanced and influenza occupational-health requirements authoritative and available before implementation

NIH should ensure that the requirements associated with “BSL-3 enhanced” containment and the required occupational health plan for specified influenza research are explicitly defined, authoritative, and available when the final Policy takes effect. Section V-E of the proposed Policy requires specified experiments involving 1918 H1N1, human H2N2, and certain HPAI H5N1 viruses to be conducted at BSL-3 enhanced containment and requires an occupational health plan. The NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules (April 2024), Section III-D-7 and Appendix G-II-C-5, currently contain detailed containment, practice, training, animal-research, and occupational-health requirements. NIH has stated in NOT-OD-26-112 that implementation of resources will include information drawn from these existing provisions. ABSA supports preserving these risk-based protections and recommend that NIH clearly identify which requirements are mandatory, whether any requirements differ from the April 2024 NIH Guidelines, and the authoritative document in which the requirements will reside. Required implementation materials should be issued concurrently with the final Policy and sufficiently

in advance of the effective date to allow institutions to assess and demonstrate compliance consistently.

COMMENTS FOR THE DRAFT NIH POLICY FOR RESEARCH INVOLVING BIOHAZARDS

Environmental Health & Engineering (EH&E) welcomes the opportunity to provide comments regarding the proposed National Institute of Health (NIH) Draft Policy for Research Involving Biohazards. EH&E is a consulting organization that works with numerous public institutions and private corporations as well as local regulatory agencies regarding life science research, biosafety, regulatory compliance and health risk analysis. As such, we have a unique and broad view of issues addressed in the draft "Policy" and appreciate that the NIH aims to update and improve biosafety oversight. Under the existing "NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules" we have had the opportunity to develop and manage many successful programs for our clients. We respectfully submit these comments for your review and consideration regarding the proposed changes to biosafety oversight.

Area of comment: Section IIIB *"Approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required."*

Comment: Many Institutional Biosafety Committees (IBCs) have established policies of de novo rewrite frequencies, which are commonly five-year terms, as well as established mechanisms to amend IBC registrations. Establishing a prescriptive three-year term for an IBC registration will significantly increase the workload for many IBCs as well as Principal Investigators without materially improving research safety.

Suggestion: Allow institutions to define de novo rewrite frequencies based on an internal assessment. Institutions may wish to align the timeframe with other compliance committees or by other operational factors. Additionally, allow the existing IBC research protocol approvals to remain valid until their scheduled renewal or expiration date.

Area of comment: Section II "*This Policy is applicable to all competing award applications, competitive revisions, proposals for contracts, and other funding agreements (e.g., Other Transactions, Cooperative Agreements) on or after [effective date will be 6 months from publication of the final Policy], and all existing awards and agreements as of that date. This Policy is applicable to all intramural research projects conducted on or after [effective date will be 6 months from publication of final Policy], including on-going or new studies. This Policy is also applicable to non-NIH funded research that is conducted on or after [effective date will be 6 months from publication of final Policy] at an institution that receives any NIH funding."*

Comment: The scope of the NIH policy would broaden oversight in certain areas that may have been approved previously for ongoing work by other institutional mechanisms (for instance toxins, certain cell lines, and wild-type organisms).

Suggestion: To limit disruption to ongoing research projects, institutions should evaluate timelines for IBC re-review of ongoing approved research projects. The six-month timeline for compliance should apply to new research projects and should begin after publishing all the final templates, definitions, and guidance documents in addition to the final "Policy".

Area of comment: Section IIIB "*Posting all incident reports on a public-facing webpage on the website of the institution, using the required incident reporting template.*"

Comment: Public transparency can make a valuable contribution to research safety when the community could be impacted by the proposed research activities. However, we believe public reporting of low-risk incidents with minimal impact on employee safety and no community risks can foster a level of concern that may be counterproductive, resulting in "information fatigue" or "over-warning", which dilutes attention and focus on the incidents that require more scrutiny. Additionally, incident reports rely heavily on worker cooperation and we are concerned that the proposed incident reporting requirements would discourage some employees from reporting.

Suggestion: Do not require institutions to publicly report: *Any incident involving research subject to the policy with an animal that is housed at BSL-1/ABSL-1 or BSL-2/ABSL-2 (e.g., bite, scratch, escape or improper disposition) or Any incident at BSL-1/ABSL-1 or BSL-2/ABSL-2 that does not involve agent-specific medical treatment when first aid is administered.* IBCs should review these incidents and ensure responses are appropriate and adequate and these will be captured in meeting minutes. Alternatively, U.S. Occupational Safety and Health Administration (OSHA) 300 Injury and Illness Logs, which are required to be posted at a facility, can be used as a reporting mechanism.

Are of comment: Section II *"For the purpose of the scope of this Policy, research involving biohazards is defined as research involving known or potential risk to human health and any of the following:*

1. *Wild-type biological agents (i.e., bacteria, viruses, fungi, or parasites) that cause disease in humans;*
2. *Cells, viruses, or organisms, other than plants, that have been genetically modified;*
3. *Toxins, prions, and other self-aggregating proteins; or*
4. *Cells or organisms, other than plants, containing 1, 2, or 3 above."*

Comment: Exemptions from Appendix F of the NIH Guidelines appear to have been removed. This will significantly increase the burden on the IBC and provide minimal benefit to research safety.

Suggestion: Define clear exemptions for hosts and vectors that present minimal risk to employees and no risk to the community. Retain the existing Section III-F-1 through III-F-8 exemptions and expand this category to include low risk plasmid cloning and protein expression in model organisms such as *Escherichia coli* (*E. coli*), BL21, and Caenorhabditis elegans.

Area of Comment: Section III-A Responsibilities of the Institution "*No research subject to this Policy may be conducted until the institution conducting the research has provided a written Biosafety Assurance through the Authorized Organizational Representative (AOR) that has been approved by NIH, setting forth compliance with this Policy. Assurances are approved by NIH for a period of up to four years. Assurance submissions will include:*

- Lines of authority and responsibility for administering the program and ensuring compliance with this Policy; to include contact information for relevant staff such as the IBC Contact, IBC Chair, and Biological Safety Officer (BSO) if applicable.
- To the maximum extent possible, weblinks to publicly-posted institutional biosafety procedures(including but not limited to documentation detailing the IBC roles, responsibilities, authorities, and processes for how biosafety risks are managed), a continuously updated IBC roster, IBC meeting minutes, incident reports, synopses of relevant staff trainings provided, and contact information for the IBC Contact, IBC Chair, and BSO (if applicable); information regarding whether the

institution conducts research in a Biosafety Level 3 (BSL-3)/Animal Biosafety Level 3 (ABSL-3) or BSL-4/ABSL-4 laboratory, research with gene drive modified organisms (GDMOs), has a BSO, receives NIH funding, and/or has an externally administered IBC.

Comment: We are concerned that the review and approval process will compromise research, given that work cannot proceed without NIH approval of the Biosafety Assurance Plan (BAP). All active, appropriately authorized research should be allowed to proceed, and there should be presumptive approval of a BAP after a reasonable review period (e.g., 30 or 60 calendar days after submissions) so that new research may begin only after appropriate IBC review and approval has been granted, where required. The requirement to post individual's names and contact information poses a potential security threat to those individuals. A single internet search of a person's name can reveal their home address and names of their family members including minor children. Given the range of unpredictable reactions to health science research , IBC personnel contact information should not be posted directly to the public. Furthermore, it is often difficult to recruit IBC members including community members given that the service on IBCs is voluntary. This additional risk will have the impact of deterring IBC membership and service.

Suggestion: Maintain the current system of submitting IBC rosters to NIH. Remove requirements to use individual's names on public facing websites.

Area of Comment (General): Increased documentation and administrative burden.

Comment: Increased documentation and administrative work will be needed for the proposed expanded scope of research requiring IBC review and approval, e.g., primary cells that may be contaminated by adventitious agents and research previously listed as exempt under Section III-F as well as the increased frequency of IBC de novo rewrite and submission (three years). The impact of this will be a shift of effort and personnel away from highly productive activities such as touring laboratories, meeting with researchers for small group training, and problem solving etc. to the office setting for generation and maintenance of documentation. It is important to recall that in 2025 the U.S. government moved to impose a cap on indirect costs (Facilities and Administrative costs) at 15% for all new and existing NIH grants. These proposed new administrative and documentation requirements per the proposed "Policy" would only add to such overhead costs with minimal or no enhancement to safety.

Suggestion: Minimize requirements for redundant or excessive IBC related documentation, reviews, and approvals such that institutional resources may be prioritized to activities shown to result in a greater research safety benefit.

Area of Comment: Review of comments and finalization of Biosafety Policy for Research Involving Biohazards.

Comment: The nature and scope of changes proposed in the new Biosafety Policy for Research Involving Biohazards are substantial. While many changes are welcomed by the new policy, some present substantial challenges to institutions.

Suggestion: Incorporate feedback from comments and publish a second draft policy for review. We agree with the efforts to modernize biosafety policy and believe this presents an excellent opportunity to better standardize the biosafety field. Careful and deliberate review will maximize the benefits of these efforts.

420. Ericka Pearce

I am responding: On behalf of myself

Name: Ericka Pearce

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): I submit these comments in my personal capacity as a Certified Biological Safety Professional (CBSP) with more than 23 years of experience supporting comprehensive biological safety and biosecurity programs in academic and federal research environments. Having worked closely with researchers, IBCs, IACUCs, institutional leadership, and federal agencies, I have seen firsthand both the challenges of conducting research and the realities of implementing effective biosafety policy. My comments reflect a belief that effective biosafety management programs should be evidence-based, practical to implement, and supportive of scientific discovery. In my experience, the best policies are those that make it easier to do the right thing, strengthen a culture of safety, and help researchers pursue innovative science safely and responsibly.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Comment 1: Modernization Should Not Become an Unfunded Mandate

I strongly support NIH's efforts to modernize biosafety oversight and expand the framework beyond recombinant and synthetic nucleic acid research to better reflect today's research landscape. The proposed policy appropriately recognizes that contemporary biosafety oversight extends beyond the scope envisioned when the NIH Guidelines were originally developed.

However, the draft substantially expands institutional responsibilities by introducing new requirements related to Biosafety Assurances, public transparency, incident reporting, training, documentation, protocol review, record retention, public posting, and oversight activities. While these new responsibilities may individually be reasonable, the draft does not identify corresponding resources or implementation support necessary to carry them out.

Real-World Implementation Impact
In a real research environment, these requirements will not be implemented by institutions in the abstract. They will be implemented by biosafety professionals, IBC administrators, investigators, laboratory personnel, occupational health staff, and institutional officials who already have extensive existing responsibilities.
Implementation is likely to require:

• Additional biosafety staffing;
• Administrative support personnel;
• New information management systems;
• Public-facing websites and document repositories;
• Incident-reporting infrastructure;
• Redaction and records-management processes;
• Expanded protocol tracking systems;
• New investigator and staff training programs; and
• Additional committee support activities.

At many institutions, particularly smaller universities, hospitals, teaching-focused institutions, and emerging research organizations, biosafety programs operate with limited staffing resources.

As a biosafety professional, I have observed that when new requirements are introduced without additional support, institutions often do not eliminate existing work. Instead, existing personnel absorb the additional responsibilities.

In practical terms, the same biosafety professional currently conducting laboratory inspections may also become responsible for reviewing public records, preparing redacted reports, maintaining websites, managing assurance documentation, developing training materials, responding to investigators, supporting IBC meetings, and completing expanded reporting requirements.

For example, reviewing and posting a publicly releasable incident report is not simply an administrative upload task. It may require consultation with legal counsel, privacy review, security review, redaction of sensitive information, quality assurance review, document management, and long-term record retention. These activities consume time from the same limited staff responsible for direct biosafety oversight.

Similarly, implementation may require reassessment of large numbers of active protocols. At previous institutions where I have worked, implementation of a framework of this scope would likely have required review of hundreds of active protocols, creation of new tracking mechanisms, and significant staff effort that would otherwise have been devoted to protocol review, laboratory inspections, investigator support, training, and incident response.

Why This Matters
The most effective biosafety activities are often the least visible administrative functions.
Safety is improved when biosafety professionals spend time:
• Working directly with investigators;
• Conducting laboratory visits;
• Providing protocol consultations;
• Performing risk assessments;
• Training laboratory personnel;
• Investigating incidents; and
• Identifying hazards before incidents occur.
If implementation results in significant shifts of time toward administrative compliance activities,

institutions may successfully complete paperwork while having less capacity available for direct risk-reduction activities.
The practical question is not whether institutions can eventually comply. Most institutions will make every effort to do so.
The question is whether compliance will require diverting limited resources away from activities that directly support safe science.

Recommendation
NIH should consider:
1. Conducting a formal implementation burden assessment.
2. Providing estimates of anticipated staffing and infrastructure requirements.
3. Developing centralized national reporting and document-management tools.
4. Providing model templates, training resources, and implementation toolkits.
5. Considering implementation supplements or funding opportunities to support compliance activities.
6. Scaling certain requirements based upon institutional size, complexity, and research portfolio.

Modernization is an important and worthwhile goal. However, successful implementation will depend not only on what institutions are required to do, but also on whether they have the resources necessary to do it effectively. The final policy should seek to improve biosafety outcomes while ensuring that limited biosafety resources remain focused on activities that most directly reduce risk and support safe research.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: Draft-NIH-Biosafety-Policy_Comments_10.19.2026.docx

We support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

1. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate

director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

2. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety

program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and

near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

3. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

4. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

5. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request.

Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

6. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

7. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): arlington

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The Six-Month Implementation Timeline Is Unrealistic

Observation
I appreciate NIH's desire to implement the proposed biosafety framework promptly and establish consistency across the research enterprise. However, the proposed six-month implementation timeline does not appear to fully account for the breadth of operational changes that institutions will need to make before compliance can reasonably be achieved.

The proposed policy introduces new requirements related to Biosafety Assurances, public transparency, protocol review processes, training, incident reporting, record retention, public posting, and governance structures. Many of these requirements will require institutions to develop entirely new processes and infrastructure.

Real-World Implementation Impact
In a real research environment, implementation involves far more than updating a policy document. Before the effective date, institutions will likely need to:
• Revise institutional policies and procedures;
• Develop Biosafety Assurance processes;
• Create or update public-facing websites;

• Establish records-management and redaction workflows;
• Modify protocol management systems;
• Create new investigator guidance;
• Develop training materials;
• Expand protocol inventories;
• Train IBC members, investigators, biosafety staff, administrators, and institutional officials; and
• Establish workflows for incident review and public reporting.

At many institutions, these changes cannot be completed by a single individual or office. They frequently require coordination among biosafety programs, research administration, information technology offices, legal counsel, communications staff, occupational health programs, compliance offices, and senior leadership.
Many institutions are still evaluating what the policy requires. In several areas, implementation guidance, examples, and operational definitions remain unavailable.

Why This Matters
A compressed implementation period is likely to produce inconsistent implementation across institutions.
Some institutions may interpret requirements conservatively and dramatically expand oversight activities. Others may delay implementation while awaiting guidance. Still others may continue existing oversight practices while attempting to determine how the new framework applies to ongoing research. The result may be variability in compliance rather than consistency.

Recommendation
NIH should consider:
1. Extending the implementation period to at least 24-36 months. The example set by the NIH NSPM-33 Research Security Program roll out is a more realistic model: where input from the regulated community helped shape the final policy and implementation approach, and the carefully planned phased rollout (2024 – present; 2027) has given institutions ample time to prepare and comply.
2. Creating phased implementation milestones.
3. Releasing implementation guidance before the compliance deadline (expected by year end 2026).
4. Providing model policies, templates, and examples.
5. Allowing a transition period during which institutions may continue operating under existing oversight structures while implementing new requirements.
A successful biosafety framework will depend not only on what is required but also on whether institutions are given sufficient time to implement those requirements consistently.

6. Other feedback relevant to this resource: Biosafety Assurance Approval Requirements Could Unintentionally Disrupt Ongoing Research

Observation
The draft policy appears to require NIH approval of a Biosafety Assurance before covered research may be conducted.
While institutional assurances can be an effective mechanism for establishing accountability, the draft does not clearly address how assurance review timelines will interact with ongoing research activities.
Real-World Implementation Impact
If implemented as written, institutions may find themselves in a situation where:
• A Biosafety Assurance has been submitted;
• The institution is actively working toward compliance;
• Existing research remains underway; but
• NIH review has not yet been completed.
In a real laboratory, this uncertainty has consequences.
Investigators may be unclear whether ongoing work can continue.
Graduate students, postdoctoral researchers, technicians, and research staff may be uncertain whether experiments should proceed.
Research administrators may be unable to provide definitive guidance regarding compliance status.

Institutions may become reluctant to initiate new projects while awaiting assurance approval.
The issue is especially significant if many institutions submit assurances simultaneously and review timelines extend beyond the implementation deadline.

Why This Matters

Research programs require predictability.
Interruptions, uncertainty, or differing institutional interpretations could affect:

- Research continuity;
- Grant performance;
- Workforce planning;
- Trainee progress; and
- Scientific productivity.

These consequences may occur even at institutions that are making good-faith efforts to comply.

Recommendation

NIH should explicitly establish:

1. Provisional or interim assurance mechanisms.
2. Continued operation while an assurance is under review.
3. Deemed approval provisions after defined review periods.
4. Clear transition language for existing awards and ongoing projects.

The final policy should avoid situations where administrative review timelines unintentionally become barriers to ongoing research.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The Policy Requires a Clear Transition Strategy

Observation
The proposed framework represents one of the most significant changes to biosafety oversight in decades. However, the draft provides limited guidance regarding how institutions should transition from existing NIH Guidelines-based programs to the new framework.
Real-World Implementation Impact
In practice, institutions will face numerous operational questions, including:
• Which existing protocols require review under the new policy?
• Which currently exempt activities become subject to oversight?
• Must previously approved projects be re-reviewed?
• How should delegated approvals transition?
• What happens to existing institutional policies and guidance documents?
Different institutions may answer these questions differently.
As a result, the same research activity could be handled differently across institutions during the transition period.

Why This Matters
Implementation periods are often when compliance risks are greatest.

Ambiguity during transition can lead to:
• Delayed studies;
• Duplicate reviews;
• Investigator confusion;
• Administrative burden; and
• Inconsistent oversight outcomes.

Recommendation
NIH should publish a dedicated transition framework that includes:
1. Grandfathering provisions.
2. Transition timelines.
3. Renewal expectations.
4. Examples of common implementation scenarios.
5. Frequently asked questions.
Providing a clear roadmap would improve consistency and reduce unnecessary burden during implementation.

426. A.T. Still University of Health Sciences

I am responding: On behalf of an organization

Name: Clayton Furman

Name of Organization: A.T. Still University of Health Sciences

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Our researchers study a variety of fields related to medicine and medical education, but we are a small institution (private university) and have only BSL-1 / BSL-2 labs, so a lot of our interest in this matter related to how such operations may be regulated.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy seems to be well-intended, but there is concern about the scope and reach of some parts of it. The idea that any research agency receiving NIH funding for any project would be subject to NIH regulations for ALL projects being conducted by that entity seems to overstep the reasonable authority of the NIH. Taken to the next logical step, hypothetically, how would this work if all sources of funding implemented similarly broad policies? Suppose, for example, that there is a research lab at a university that receives NIH funding and another lab (or perhaps 20 others) at the same university primarily funding from another source (or other sources). If each funding source were to arbitrarily demand control over how the university conducts all of its research, regardless of funding source, and those requirements were to conflict with one another, that university would be forces to cut ties with one or more sources of funding in order to comply with NIH requirements or vice-versa. Overall, this can only be detrimental to the research, so we do not believe it is fair or reasonable that NIH should make such a demand. Asking that projects directly funding by NIH be conducted in accordance with NIH policy is, of course, a reasonable condition for receiving NIH funding; forcing all projects to comply with NIH rules when NIH doesn't have anything to do with them is not.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Overall, the policy looks to have good intentions and seems to address many of the inconsistencies that might exist within the modern research world. As a smaller entity with only lower-level labs (BSL-1 mostly, and occasionally some BSL-2 work), our principle concern is that the new policy may actually over-stipulate details regarding the composition of an IBC. Put simply, while the objective is on-point, the implementation may not be practical for smaller research entities. It is likely to create an excessive administrative (and potentially financial) burden to maintain a committee with such specific composition when the research being conducted doesn't really justify so much overhead or oversight. It seems as if maybe that part of the policy was written with BSL-3 and BSL-4 labs in mind, and for those applications, it would make sense; the problem is that the exact language in the policy does not allow the IBC to be scaled

appropriately for cases where that level simply isn't necessary. This would be burdensome for an entity of our size and might completely put a small independent lab out of business.

3. Continued utility of Risk Groups: We have not had any issue with nor found any deficiency in the existing system using BSL as per BMBL, so in our experience, there is no practical need to modify this system. The existing BSL system has been in place for years, and I think it would be fair to say that virtually all existing and currently operating laboratories working in related fields are configured to comply with that system. Changing it without a very serious reason would only create more expense and administrative burden for researchers who are already operating on bare minimum resources as it is, in many cases. The idea of designating a risk group based upon specific criteria is sound, but it should only be used as a means of determining what level of biosafety is required, not as a substitute for the existing BSL system.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Please see the answer to question #1: As it is currently worded, this policy would force compliance with NIH policy upon non-NIH funded projects at any institution receiving NIH funding for any project, and that does not seems fair or reasonable. Publication of "good practices" or the like is a wonderful idea; attempting to force it upon research that is not even supported by NIH in any way can only have detrimental effects to the overall "research industry", making it more difficult to obtain research funding and/or more burdensome to comply with what may or may not even be applicable or worthwhile policies without any provision of resources. What entitles NIH to dictate how a researcher should conduct the work when NIH isn't providing any funding or other resources to support that work? We're all in favor of safety in the lab, but historically, it has never been practical for any organization to issue demands without also issuing resources to enable compliance. In short, if NIH isn't willing to pay the cost of compliance with all of the NIH policies, then NIH doesn't have any right to expect anyone to comply either. As written, the new policy could be interpreted to be retroactively applicable, forcing entities already receiving NIH funding (even if it's only 1% of their total research budget, for example) to have to comply with NIH policy while having no vote on that policy and no additional funding to support compliance provided by NIH. If it's only a small percentage of the overall research budget for a given organization, perhaps the organization may choose to break ties with NIH and ignore the policy entirely, which would not serve NIH or the researcher. If it is a large percentage of a small research organization's budget, that entity may not have the ability to continue functioning without NIH funding and may not really have the resources to comply with NIH policy across the board with other projects, so this effectively borders on being coercive in nature, which is surely not the intention.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: This is bordering on micro-management, honestly. If NIH wants to set forth specific requirements for reporting, etc. as a requirement for obtaining and renewing NIH funding, then that is their prerogative, but it does not seem practical or reasonable for a high-level organization such as NIH to have any need (nevermind the actual practical resources) to manage such details as how individual research organizations keep their meeting minutes. Surely, NIH resources could be put to better use elsewhere. If there is not actually any intention to review or manage the minutia, then it makes no sense to regulate it either, so either way, this seems like a detail that might be too small to really be worth of inclusion in such a policy.

6. Other feedback relevant to this resource: Overall, the policy is good -- it has two primary flaws, for lack of a better term. First, the language granting NIH the authority to mandate compliance across all projects operated by anyone who receives NIH funding for any project needs to be removed -- no organization has the right to arbitrarily give itself authority over tasks in which that organization is not directly involved, and NIH is no exception. Requiring compliance for NIH-funded projects is fine, provided the recipient of NIH funding consents to that requirement before receiving the money. Any attempt to change the arrangement after the money has already been granted is inappropriate, and as written, this language would allow exactly that.

The second area that needs work is the overly detailed establishment and maintenance of IBCs. The idea of having such a committee is a good one; going so far as to micro-manage exactly who should be on the committee and how they should keep minutes is not. An internal committee appropriate to the size of the institution and the scope of the research is a great idea, but as it is currently specified, the committee could potentially cost more in terms of both time and money than the research itself for smaller research entities and is plain and simply not necessary for lower-level biosafety threats such as those typically handled at BSL-1 and BSL-2 facilities. As written, the precise details of how the IBC must be constituted, etc. would seem applicable for only BSL-3 and higher, so it needs to be revamped to permit reasonable scaling for labs where the biohazards simply do not justify that degree of oversight and over-management.

Once those two issues are fixed, the rest seems to be a step in the right direction -- thank you for all the hard work and your continued support of scientific research!

Uploaded File: ATSU_NIH_Feedback.docx

Description: This is the official response from ATSU, as agreed upon by our own internal review boards and experts, approved by university leadership. The responses to the questions above are largely the same idea but without institutional review, so this document should be taken as our official response.

RE: Notice NOT-OD-26-112 — Public Comment on Draft Biosafety Oversight Policy Framework

To Whom It May Concern:

We appreciate the opportunity to comment on NOT-OD-26-112. We fully support the NIH's commitment to biosafety. We write to offer targeted recommendations regarding administrative harmonization for co-regulated entities and scalability for committee composition requirements.

1. Regulatory Harmonization and Administrative Efficiency

We strongly support the provision in Section II allowing research subject to this Policy to proceed under the primary oversight of another federal agency once applicable clearances are obtained. This deference prevents duplicate regulatory burdens for co-regulated facilities.

To ensure this principle translates effectively into practice across all institutional operations, we request that the final policy address a key operational inefficiency:

- **Streamlined Incident & Administrative Reporting**: Where an incident or protocol is already subject to reporting under another federal agency, permit institutions to submit copies of primary agency filings to fulfill NIH reporting requirements, avoiding redundant multi-part documentation.

2. Scalability of Committee Structure for Smaller Entities and Low-Risk Work

We applaud the NIH for introducing "delegated review" in Section IV for lower-risk (Category C) research, recognizing that routine protocol reviews do not require the administrative weight of a convened full committee. However, a significant operational disconnect remains between protocol review workflows and institutional roster mandates.

While lower-risk protocols can be cleared by a single designated reviewer, Section III-B still requires every grantee institution to recruit, onboard, and maintain a standing 5-member Institutional Biosafety Committee–including two non-affiliated community members and specialized technical experts. For smaller institutions, single-lab operations, or facilities conducting exclusively low-risk research, maintaining a standing 5-member panel solely for roster compliance presents an unnecessary administrative burden.

To align governance structure with protocol risk, we request:

- **Shared and Regional IBC Pathways**: Explicitly permit smaller or lower-risk entities to fulfill Section III-B committee requirements by utilizing an established regional, shared, or centralized IBC rather than mandating an independent standing committee at every physical grantee site.

- **Conditional Committee Composition**: Clarify that specialized technical expertise (e.g., plant or animal containment specialists) and expanded committee sizes are required conditionally based on active research modalities, allowing institutions conducting standard bench research to maintain a proportional standing committee with ad-hoc technical consultants engaged as needed.

Tailoring administrative requirements to fit the scale, risk profile, and funding structures of research entities will improve overall institutional compliance without placing undue burdens on smaller institutions.

Thank you for your consideration of these recommendations.

427. Leyma De Haro

I am responding: On behalf of myself

Name: Leyma De Haro

Name of Organization:

Type of Organization: Not Applicable

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support NIH's proposal to expand biosafety oversight beyond research involving recombinant or synthetic nucleic acid molecules. This is an important modernization of the current framework. However, the proposed policy should more explicitly address emerging technologies that challenge conventional definitions of biological hazards and established risk assessment methodologies.

I recommend that NIH consider the following areas:
1. Mirror life and mirror-image biological systems. The policy does not explicitly address mirror life. Although hypothetical self-replicating mirror organisms could fall within the definition of novel organisms, their potential biological and ecological hazards may not be adequately characterized using conventional risk assessment approaches. NIH should distinguish between research involving nonreplicating mirror-image biomolecules, which have legitimate scientific and therapeutic applications, and research directed toward creating self-replicating mirror organisms, which warrants specialized precautionary oversight.

2. AI-designed biological systems. I welcome the explicit recognition of artificial intelligence (AI) in the proposed definition of novel agents or organisms. However, this definition should also account for AI-designed proteins, genetic circuits, synthetic genomes, and other de novo biological systems that may lack recognizable natural counterparts. Risk assessment should consider biological function, phenotype, potential emergent properties, and scientific uncertainty, rather than relying primarily on parental organisms or the origins of genetic sequences.

3. Autonomous and AI-directed laboratories. The policy should explicitly address biological research conducted through automated and self-driving laboratories. These systems may autonomously select experiments, modify parameters, and execute laboratory procedures. NIH should clarify when activities conducted by such systems fall within an existing institutional approval and when modifications require renewed risk assessment or IBC review.

4. Cyberbiosecurity. Modern biological research increasingly depends on digital infrastructure, including AI systems, electronic research protocols, laboratory information management systems, and automated instrumentation. Compromise of these systems can create physical biosafety and biosecurity risks. NIH should explicitly recognize cyberbiosecurity vulnerabilities when they could affect biological containment, experimental integrity, or safe laboratory operations.

5. Environmental and ecological risks. The definition of biohazards emphasizes human health. NIH should clarify whether and how the policy addresses engineered biological systems that may present significant ecological or environmental hazards without necessarily posing direct pathogenic risks to humans.

Overall, I recommend that NIH adopt a technology-neutral, risk-based approach that considers not only the intrinsic hazards of biological agents but also their functions, experimental applications, interactions with other systems, and associated uncertainties. The policy should remain sufficiently flexible to accommodate future developments in synthetic biology, AI, and laboratory automation, while avoiding unnecessary restrictions on well-characterized, low-risk research.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I support NIH's proposed tiered oversight framework, provided that oversight responsibilities are proportionate to the risks, complexity, and scientific uncertainties associated with the research. A risk-based approach should preserve institutional flexibility for routine, well-characterized research while ensuring that activities involving novel or potentially consequential biological hazards receive appropriate scrutiny.

I recommend that NIH consider the following:
1. Clear criteria for federal versus institutional oversight. NIH should establish consistent, scientifically justified criteria for determining which research activities require federal review and which can be managed through Institutional Biosafety Committees (IBCs). Federal oversight should focus on activities presenting significant or poorly characterized hazards, particularly when risks may extend beyond the institution conducting the research. Local oversight should remain the primary mechanism for activities involving established hazards and validated containment practices.

2. Oversight of emerging technologies. Research involving AI-designed biological systems, novel synthetic organisms, and potentially self-replicating mirror biological systems may introduce uncertainties that are not adequately captured by conventional Risk Group classifications. NIH should establish clear escalation criteria for research involving biological systems with potentially significant but poorly characterized hazards. Such criteria should be based on the properties and risks of the proposed research, rather than the mere use of an emerging technology.

3. Adaptive oversight of autonomous laboratories. AI-directed and self-driving laboratories may modify experimental parameters or select subsequent experiments without direct human intervention at every step. NIH should consider an oversight model in which institutions approve a defined experimental operating envelope. Activities conducted within that envelope could proceed under existing approval, while modifications introducing new hazards or materially changing the original risk assessment would require renewed review. This would support innovation while maintaining appropriate human accountability.

4. Strengthening IBC technical expertise. The increasing complexity of synthetic biology and AI-enabled research may exceed the specialized expertise available within individual IBCs. NIH should encourage access to external subject-matter experts, shared institutional resources, and specialized training in emerging biological technologies. Institutions should not necessarily be required to maintain permanent expertise in every emerging field, provided they can obtain qualified independent review when needed.

5. Consistency without unnecessary administrative burden. Institutions may interpret similar research activities differently, resulting in inconsistent containment requirements or oversight decisions. NIH should provide standardized risk assessment methodologies, decision-support tools, and clear criteria for delegated review. AI-assisted tools could help investigators and IBCs identify relevant hazards, review scientific evidence, and document assessments. However, final decisions should remain with qualified human reviewers.

6. Periodic reassessment based on emerging evidence. Oversight classifications should be revisited when new scientific findings materially change the understanding of a biological system's hazards or when experimental activities change. NIH should provide guidance on reassessment triggers rather than relying exclusively on fixed review intervals.

Overall, I recommend a framework in which institutional oversight remains the foundation of routine biosafety governance, while federal oversight provides consistency, specialized expertise, and additional review for research presenting substantial or poorly characterized risks. Importantly, the level of oversight should be determined by the actual hazards and uncertainties of the proposed work, not simply by the novelty of the technology being used.

3. Continued utility of Risk Groups: I support the continued use of Risk Groups (RGs) as a baseline for biological risk assessment. RG classifications provide a useful starting point for identifying the established hazards associated with biological agents. However, additional clarification, standardized guidance, and practical training are needed to ensure that RGs are interpreted and applied consistently, particularly when biological agents are genetically modified.

Risk Groups and Biosafety Levels (BSLs) serve distinct but complementary purposes. RG classifications characterize the hazards associated with biological agents, whereas BSLs describe the laboratory practices, safety equipment, and facility safeguards needed to conduct specific activities safely. An agent's Risk Group should inform, but should not automatically determine, the appropriate Biosafety Level. The final containment determination should result from a comprehensive, activity-specific risk assessment.

I recommend that NIH address the following:
1. Clarify the relationship between RGs and BSLs. NIH should provide explicit guidance explaining how RG classifications inform containment decisions without establishing an automatic correspondence between RG and BSL numbers. Practical examples would help investigators and IBCs understand when the appropriate containment level may differ from the agent's Risk Group.

2. Provide guidance for genetically modified and synthetic biological agents. Genetic modifications can alter an agent's characteristics, including pathogenicity, host range, transmissibility, environmental

stability, and other relevant biological properties. NIH should clarify how these changes should be evaluated when determining whether an existing RG classification remains appropriate. This guidance should also address novel synthetic biological systems for which conventional RG classifications may have limited applicability.

3. Standardize risk assessment training. NIH should develop practical training materials for principal investigators, biosafety professionals, and IBC members. Training should emphasize the distinction between agent hazards and activity-specific risks, the selection of appropriate containment measures, and the evaluation of genetic modifications. Case studies involving conventional pathogens, engineered organisms, and emerging biotechnologies would be particularly valuable.

4. Promote consistency across institutions. Different institutions may reach different containment decisions for comparable research activities. Although some variation is justified by differences in facilities, procedures, and institutional capabilities, NIH should provide standardized risk assessment templates, decision-support guidance, and illustrative examples to reduce inconsistencies arising from misinterpretation of RG classifications.

5. Clarify the relationship with the BMBL. NIH should ensure that its guidance is consistent with the risk assessment principles outlined in Biosafety in Microbiological and Biomedical Laboratories (BMBL). Clear cross-references would help institutions apply both documents appropriately and avoid confusion regarding their respective purposes.

Overall, I recommend retaining Risk Groups as a foundational component of biosafety risk assessment while strengthening guidance on their interpretation and limitations. The priority should be to improve the quality and consistency of risk assessments through clear definitions, practical examples, and standardized training, rather than replacing RG classifications with BSL designations.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I support expanding the scope of biosafety oversight beyond NIH-funded institutions rather than relying primarily on voluntary compliance. Biological hazards do not depend on an institution's funding source, and the potential consequences of inadequate biosafety practices can extend beyond laboratory personnel to surrounding communities and the environment.

The discovery of an unauthorized biological laboratory in Reedley, California, in 2023 demonstrated significant weaknesses in the existing regulatory and oversight framework. This incident raised serious questions about how laboratories handling potentially hazardous biological materials can operate outside established institutional biosafety programs and how federal, state, and local authorities coordinate oversight and enforcement.

Voluntary compliance alone is insufficient to address these vulnerabilities. Institutions that already prioritize biosafety are more likely to adopt voluntary standards, while laboratories with inadequate expertise, poor safety practices, or deliberate disregard for regulatory requirements may remain outside the oversight system.

I recommend that NIH consider the following:

1. Expand the applicability of biosafety oversight. NIH should work with other federal agencies and relevant state authorities to develop a framework establishing minimum biosafety requirements for laboratories conducting research with potentially hazardous biological agents, regardless of whether they receive NIH funding. Any expansion beyond NIH's current authority should be supported by appropriate regulatory or legislative mechanisms.

2. Establish minimum institutional biosafety requirements. Laboratories conducting covered biological research should be required to demonstrate appropriate risk assessments, qualified biosafety oversight, personnel training, containment practices, biological material management, and emergency response procedures. Requirements should remain proportionate to the hazards and activities involved.

3. Strengthen laboratory accountability and regulatory coordination. Federal, state, and local authorities should have clearly defined responsibilities for identifying and responding to laboratories conducting potentially hazardous biological activities without appropriate oversight. Mechanisms for information sharing, inspections, and enforcement should be strengthened to prevent regulatory gaps.

4. Require qualified biosafety expertise. Biosafety assessments and oversight of hazardous biological research should be performed or reviewed by appropriately qualified professionals. Self-assessment tools and general educational resources may support compliance, but they should not substitute for competent biosafety review or independent oversight when the risks warrant it.

5. Establish mechanisms for identifying laboratories operating outside established oversight systems. NIH should collaborate with relevant regulatory agencies to explore proportionate laboratory registration, notification, or licensing requirements for research involving specified biological hazards. These mechanisms should help authorities identify facilities conducting covered activities and verify that appropriate biosafety protections are in place.

6. Preserve risk-based proportionality. Expanded oversight should not impose unnecessary requirements on routine, low-risk biological activities. Oversight requirements should be based on the actual hazards, experimental activities, and potential consequences of laboratory operations rather than institutional affiliation or funding status.

I recommend that NIH move beyond encouraging voluntary compliance and support the development of a coordinated national framework for biosafety oversight. The objective should be to ensure that laboratories conducting potentially hazardous biological research are subject to appropriate minimum safety standards, qualified oversight, and enforceable accountability mechanisms, regardless of their funding source.

The Reedley laboratory incident demonstrates the potential consequences of regulatory gaps. A modernized national biosafety framework should seek to prevent similar situations rather than rely on voluntary participation by institutions that may lack the expertise, resources, or willingness to establish adequate biosafety practices.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Modernize biosafety incident reporting through a centralized, web-based information system.
I strongly recommend that NIH move beyond PDF-based incident reporting and establish a secure, centralized online reporting system. Although standardized PDF templates may improve consistency in documentation, they are not an optimal mechanism for collecting, managing, aggregating, and analyzing incident data across institutions.

The proposed National Biosafety Data and Safety Analysis Center (NBDSAC) represents an important opportunity to modernize biosafety surveillance and establish a national evidence base for laboratory safety. However, realizing this potential will require structured, interoperable, machine-readable data rather than relying primarily on individual PDF submissions.

An online reporting system should incorporate the following capabilities:

1. Structured electronic reporting: Standardized fields, controlled terminology, and appropriate validation rules to facilitate consistent data collection and reduce incomplete or incompatible submissions.

2. Incident tracking and follow-up: Unique incident identifiers, submission histories, investigation updates, corrective-action tracking, and mechanisms for documenting the effectiveness of preventive interventions.

3. Data aggregation and trend analysis: The ability to analyze incidents and near misses across institutions, biological agents, experimental activities, equipment types, contributing factors, and time periods. Such analyses should account for differences in institutional reporting practices and laboratory activities.

4. Integration with institutional systems: Secure interfaces and standardized data formats that allow institutions to submit information from existing environmental health and safety, incident management, and laboratory information systems without unnecessary duplication of effort.

5. Data security and confidentiality: Role-based access controls, encryption, appropriate de-identification, and clear data governance policies to protect confidential research, personnel information, and security-sensitive laboratory details.

6. Analytical and AI-assisted capabilities: A properly structured database could eventually support advanced statistical analyses, machine learning, and AI-assisted identification of recurring failure mechanisms and emerging biosafety risks. Such applications should be scientifically validated and subject to appropriate human oversight.

7. Institutional feedback and benchmarking: Participating institutions should be able to access their own incident histories, track corrective actions, and receive aggregated national findings and lessons learned. Any benchmarking should account for differences in reporting culture, institutional research activities, and exposure opportunities.

NIH could retain downloadable PDF templates as supplementary resources or temporary alternatives during implementation. However, they should not become the primary long-term mechanism for national biosafety incident reporting. I encourage NIH to design the reporting platform in coordination with the proposed NBDSAC, biosafety professionals, institutional reporting personnel, and relevant federal agencies. The system should support both regulatory reporting and scientific analysis while minimizing administrative burden.

The objective should not simply be to digitize a form. It should be to establish a modern national biosafety information system capable of transforming incident reports into actionable knowledge that improves laboratory safety and prevents future incidents.

6. Other feedback relevant to this resource: I support NIH's plan to develop supplemental implementation resources. These materials will be essential to ensuring consistent interpretation and application of the revised policy across institutions.

I recommend prioritizing the following areas:
1. Risk Group (RG) classifications and Biosafety Level (BSL) determinations. Provide clear guidance on the distinction between RGs and BSLs, particularly when biological agents are genetically modified. Practical examples should illustrate how agent characteristics, experimental procedures, and available containment measures inform the final biosafety assessment. Standardized training materials for investigators, biosafety professionals, and IBC members would improve consistency across institutions.

2. IBC review and oversight procedures. Provide examples clarifying which research activities require full IBC review, which qualify for delegated review, and which changes to approved protocols require reassessment. Guidance should also explain when institutions must consult NIH regarding novel or emerging agents for which established containment recommendations are unavailable.

3. Incident reporting and documentation. Provide guidance distinguishing initial incident notifications from final investigation reports, including expectations for root cause analysis, corrective actions, and verification of their effectiveness. I strongly recommend replacing PDF-based reporting as the primary submission mechanism with a secure, structured online reporting system. Such a system would facilitate tracking, consistency, data aggregation, and trend analysis, particularly in support of the proposed National Biosafety Data and Safety Analysis Center (NBDSAC).

4. Implementation examples and training. Provide practical case studies and completed examples of risk assessments, IBC documentation, and incident investigations. These resources would be particularly valuable during the transition from the current NIH Guidelines to the proposed policy.

Overall, implementation resources should focus on clarifying policy requirements, supporting consistent institutional decisions, and reducing unnecessary administrative burden. They should complement, rather than replace, the professional judgment of qualified biosafety personnel.

To: National Institutes of Health, Office of Science Policy

Re: Public comments on NOT-OD-26-112 — Draft NIH Biosafety Policy for Research Involving Biohazards

Dear NIH Office of Science Policy:

I am submitting the attached comments in my individual professional capacity to support the development of a scientifically grounded, practical, and forward-looking NIH biosafety framework. I am a biomedical scientist with a Ph.D. in molecular genetics and microbiology and extensive experience in biosafety, biosecurity, institutional risk assessment, high-containment laboratories, and Institutional Biosafety Committee oversight. My professional work has included research universities, national laboratories, public-health laboratories, and international biorisk management activities.

My scholarship focuses in part on emerging biological technologies and their governance. I am the author of Biosecurity in the Age of Synthetic Biology (CRC Press, 2024). My publications include “Biosecurity Risk Assessment for the Use of Artificial Intelligence in Synthetic Biology” (Applied Biosafety, 2024) and “Using Embodied AI Agents to Automate Biorisk Management Tasks in High-Containment Laboratories” (Applied Biosafety, 2025).

I participated in the February 2025 Spirit of Asilomar and the Future of Biotechnology summit, convened on the 50th anniversary of the original Asilomar meeting. Following the summit, I coauthored “The Spirit of Asilomar: Lessons for the Next Era of Biotechnology Governance” (Trends in Biotechnology, 2025; DOI: 10.1016/j.tibtech.2025.05.013). I also endorsed several of the summit’s published entreaties, including “The Importance of Redlines in the Life Sciences,” “Condemning & Making Obsolete Biological Weapons,” “Safeguarding the Benefits of Synthetic Cell Engineering,” and “A Statement of Shared Stewardship.” These entreaties express the views of their respective authors and endorsers; they are not consensus statements of all conference participants.

I welcome NIH’s effort to move beyond a framework centered on recombinant and synthetic nucleic acids toward broader, risk-based biosafety oversight. The attached comments focus on issues likely to become increasingly consequential: AI-designed and novel synthetic biological systems, mirror-image biology, autonomous experimentation, AI-assisted risk assessment, cyberbiosecurity, biosafety incident-data infrastructure, and clear institutional oversight responsibilities. These recommendations are intended to strengthen biosafety without unduly constraining beneficial scientific research.

Thank you for considering these comments as NIH develops the final policy.

Sincerely,

Leyma P. De Haro, Ph.D., RBP (ABSA)

Submitted in an individual professional capacity

Summary of Comments on the Draft NIH Biosafety Policy

NIH Notice NOT-OD-26-112 | Draft policy for research involving biohazards | October 19, 2026

Purpose. This working summary identifies recommendations for strengthening the proposed policy with respect to emerging biotechnology, institutional oversight, and practical implementation. These are proposed comments, not requirements already established by NIH.

1. Address mirror life explicitly

Priority: High | Relevant draft sections: Sections II, IV-1, V-A, V-C

Clarify whether wholly or partially mirror-image biological systems fall within the definition of a biohazard or novel organism. Distinguish useful research on nonreplicating mirror-image molecules from work toward self-replicating mirror organisms. Provide a precautionary referral and assessment pathway for the latter, addressing uncertainty about biological interactions, environmental persistence, detection, and effective containment. Avoid assigning conventional Risk Groups without adequate evidence.

2. Modernize assessment of AI-designed and de novo biological systems

Priority: High | Relevant draft sections: Sections II, V-B, V-C

Explicitly address AI-designed proteins, genetic circuits, and organisms with no meaningful parental organism. Supplement sequence provenance and parental Risk Group considerations with functional, phenotype-based, context-dependent, and uncertainty-aware assessment. Treat lack of an identified hazardous parent as insufficient evidence of safety.

3. Define oversight for autonomous and AI-directed experiments

Priority: High | Relevant draft sections: Sections III-B, III-C, V-D, V-E

Specify how IBC-approved research applies when an automated or AI-driven system changes experimental parameters or selects subsequent experiments. Encourage defined, validated operating envelopes, pre-established escalation triggers, audit trails, safeguards against out-of-scope operations, and human authority to intervene. Require renewed review when changes materially alter risk.

4. Enable validated AI-assisted biosafety risk assessment

Priority: High | Relevant draft sections: Sections III-B, III-C, V

Recognize computational decision-support tools for literature synthesis, protocol triage, identification of missing hazard information, and documentation. Make clear that IBCs and investigators retain decision authority. Provide guidance on tool validation, evidence traceability, accuracy, uncertainty, confidentiality, and periodic reevaluation.

5. Build the National Biosafety Data and Safety Analysis Center as a scientific resource

Priority: High | Relevant draft sections: Sections II, III-C, III-D

Support the proposed center and develop standardized, interoperable incident and near-miss data fields, including exposure context, causal factors, process and equipment conditions, and corrective actions. Enable rigorous trend analysis while protecting confidentiality and guarding against re-identification. Account for reporting-culture differences before making comparisons among institutions.

6. Integrate cyberbiosecurity where digital compromise creates biological risk

Priority: High | Relevant draft sections: Sections III-A, III-B, V-D, V-E

Include proportionate evaluation of connected instruments, automated systems, electronic protocols, biological inventories, laboratory information systems, and facility controls. Clarify coordination with institutional cybersecurity teams, and when a digital incident that affects containment or safe experimental operation warrants biosafety investigation or reporting.

7. Clarify boundaries of biosafety, biosecurity, and dual-use oversight

Priority: Medium | Relevant draft sections: Sections II, III-B, IV

Explain referral and coordination mechanisms among IBCs, institutional research security functions, and applicable federal oversight frameworks. Do not imply that IBCs alone should adjudicate all dual-use or information-security issues. Avoid duplicate reviews and conflicting determinations.

8. Strengthen institutional implementation and proportional oversight

Priority: Medium | Relevant draft sections: Sections II, III-A, III-B, IV

Provide actionable criteria for delegated review and for determining when a protocol change requires reassessment. Evaluate the net workload associated with expanded coverage, Biosafety Assurances, three-year de novo reviews, incident reporting, and public posting. Supply standardized templates, training, transition support, and realistic workload assumptions.

9. Balance transparency with protection of sensitive information

Priority: Medium | Relevant draft sections: Sections III-A, III-B

Clarify redaction criteria for IBC minutes and incident reports. Protect confidential research details, individual privacy, physical security vulnerabilities, and sensitive operational information while ensuring meaningful public accountability. Provide consistent examples and a process for resolving disclosure disagreements.

10. Clarify environmental and nonhuman risk boundaries

Priority: Medium | Relevant draft sections: Sections II, V-A, V-B, V-E

Resolve the tension between a scope centered on human health and risk assessments that also consider ecological and nonhuman impacts. Explain handling of gene-drive systems and other novel synthetic organisms for which environmental effects may be central, including where field-release activities fall outside this laboratory-focused policy.

Overall recommendation

Retain the proposed expansion from recombinant-DNA-focused guidance to risk-based oversight of biohazards. Strengthen it with forward-looking provisions for novel biological architectures, AI-enabled design and experimentation, and digitally connected laboratories. Pair these provisions with scientifically grounded, proportionate review procedures and a national learning system for biosafety incidents and near misses.

428. University of Michigan

I am responding: On behalf of an organization

Name: William Greer

Name of Organization: University of Michigan

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: 1. Purpose and program identity - Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation - Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.
Requests for consideration. Identify activities requiring no submission or review, documentation only, or

prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

3. Institutional accountability and Biosafety Assurances - Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.
Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.
Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

4. IBC establishment functions and operations - Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.
Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language. The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.
Experienced program leadership and the Biological Safety Officer
The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.
Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting - Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.
Clinical activities and oversight endpoints
Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.
Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.
Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest
The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.
Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

6. NIH review and containment determinations - Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

7. IBC review pathways and clinical oversight - Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.
Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.
Proposed designated member review procedure
Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.
If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer the submission to the full committee for review. Multiple reviewers must agree; unresolved differences shall go to the full committee.
Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

3. Continued utility of Risk Groups: 8. Risk assessment and specialized materials - Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.
Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

6. Other feedback relevant to this resource: Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.
Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specifically define the required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.
Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

9. NIH implementation responsibilities and coordination - Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

Uploaded File: University-of-Michigan-Comments_NIH_Biohazards_Policy.docx

Community Comments on the Draft NIH Biosafety Policy

Recommendations to the National Institutes of Health Office of Science Policy

The University of Michigan supports the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. The comments presented summarize the University's detailed discussions, comments, and priority requests and follow the draft policy's section order.

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specifically define the required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.

Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving

Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer the submission to the full committee for review. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Please see attached document.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Please see attached document.

3. Continued utility of Risk Groups: Please see attached document.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Please see attached document.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Please see attached document.

6. Other feedback relevant to this resource: Please see attached document.

Uploaded File: Response-Draft-NIH-Biosafety-Policy.pdf

Description: The attached document provides a thorough response to all areas listed above.

The Draft NIH Biosafety Policy for Research Involving Biohazards (the Policy) is intended to be an update to the existing NIH Guidelines for Research Involving Recombinant and Synthetic Nucleic Acid Molecules (NIH Guidelines). However, the result is a policy that presents a confusing mixture of incomplete rules that ignores many key features of the NIH Guidelines that were crafted and refined over decades of consideration and interpretation. The new policy was an attempt to streamline the oversight of the Institutional Biosafety Committee (IBC) and provide more authority. Unfortunately, the ambiguity and lack of examples create greater confusion where little to none had existed.

The Policy shifts the focus of its oversight to human-centric pathogens in a way that ignores the potential negative economic and societal outcomes of pathogens that infect animals and plants. While the Policy states that pathogens infecting animals and plants will be addressed by policies from other agencies, the lack of such policies is very notable and concerning. It is strongly recommended that the Policy reconsider the absence of animal and plant pathogens that do not infect humans to ensure appropriate and consistent oversight is provided.

The Policy sets forth an extremely aggressive timeline for implementation and compliance. Institutions will have six months from Policy publication to implement all changes. The Policy fails to provide a framework for how ongoing basic sciences research and clinical research that is subject to the NIH Guidelines will be impacted. For example: will review/approval of research by the IBC be halted pending acceptance of the institutions AOR assurance by the NIH? Moreover, guidance will necessarily change for how institutions will handle HGT studies (which are not directly referenced or redefined in the Policy) and how IBCs are expected to work with the local Institutional Review Board (IRB)

Compliance with this policy will require changes in institutional policy, training materials, printed materials, and significant changes to oversight systems. Electronic systems that are employed to ensure compliance with applicable federal policies are often managed and updated by third-party companies. Institutions will be dependent on the speed with which these companies will be able to complete the necessary changes. Making changes will also be dependent upon accurate interpretation of the Policy, which will likely not be settled by the time it is published. The time and financial costs of making such changes will be significant.

The Policy is also being implemented within a similar timeframe as the United States Government Policy for Stopping High-Risk Life Sciences Research (DGOF Policy). There is a high degree of overlap between these policies but nuanced differences will make implementation of both policies at the same time an incredibly difficult burden on both research professionals and administrative staff. Moreover, the Policy states that institutions must demonstrate compliance within 6 months of implementation but no description of how compliance will be demonstrated.

There are noted gaps within the definitions provided within the Policy that are cause for concern. In particular, the definition of Biological Agent focuses on agents that cause disease in healthy individuals. This definition does not account for microorganisms that are commensal in humans but may exacerbate health conditions if exposure occurs. Agents that cause disease in humans are worth studying, and therefore providing oversight, due to their potential to cause disease in humans if certain conditions are met or fortuitous genetic modifications naturally occur. This definition also does not encompass agents that do not cause disease in humans but enhance the pathogenicity of the bacteria they infect, e.g., phages.

The focus on agents that cause disease in humans is also concerning because the ecosystem is broad and includes animals. Biological agents that are infectious to animals or plants but not humans could have significant societal and economic impacts. Absent guidance from other, relevant agencies, it is unclear how oversight will be provided to these agents.

The definition of toxin is also ambiguous as it does not describe what is meant by harm to a human. Some small proteins, such as allergens, are not toxic but are still capable of causing acute harm or harm following long-term exposure. Overall, the definitions need to be more descriptive and less available for interpretation.

Similar to the definitions section, the roles and responsibilities section, Section III, would greatly benefit from more precise and descriptive language as well as examples of how to implement this policy. Examples should be provided for biosafety assurance, posting minutes, reporting and posting incidents, and specific training requirements. The requirement for a Biosafety Officer (BSO) is also unclear: some sections state that it is required for research at BSL3 and higher while other sections state that a BSO is required for research with organisms that are Risk Group (RG) 3 and higher. These statements are incongruous and conflate Risk Group with Biocontainment Level. Moreover, many responsibilities are assigned to the BSO throughout this policy despite the fact that the position is not formally required in most instances when such work will be conducted (at BSL2 and below). Additional guidance regarding what responsibilities the BSO may delegate and to whom would also be helpful.

This section also states that the NIH must be petitioned to determine the appropriate biocontainment level or reduce the biocontainment level for RG3 and RG4 organisms *each time* a request is made. Lentiviral vectors are ubiquitous in life sciences research despite the parent organism earning a RG3 rating. Nevertheless, these agents are typically handled at BSL2. Will the NIH be providing a blanket downgrading of these agents to BSL2? Will such a request be granted at an institution level? Or would downgrading such organisms require a different request dependent upon transgene?

The role and responsibilities of the Principal Investigator (PI) are also outlined in this section but would benefit from additional clarity. This section states that the PI must initiate the risk assessment process. Guidance for how this should be documented would support this process. The PI is required to submit amendments when biorisk

changes but this section does not provide guidance for how the alteration (or increase) in risk is determined. Lastly, additional guidance regarding the PI's responsibility to submit voluntary safety/near miss information would be appreciated and if this information should be relayed through the BSO and/or the IBC and/or another institutional official.

This section should also provide guidance about how the NIH will assign containment levels for both novel and existing biological agents. There is some information about this process, however, it is buried in four short bullet points at the end of the document and provides insufficient guidance. Additional guidance should also be provided regarding so-called "low" or "high" risk activities. These qualifiers for risk are relative and cannot be consistently applied. Administrative and engineering controls are intended to reduce risk before a researcher even begins work. Thus, risk is inherently lower with well-trained staff and well-appointed facilities. Moreover, some research institutions are more risk-tolerant than others.

The Policy should also consider bringing forward major tenants of the NIH Guidelines that continue to be relevant. For example, the Policy no longer explicitly prohibits cloning of clinically relevant drug selection markers into human pathogens. While this activity would likely be prohibited or heavily regulated by the DGOF Policy, that policy is not directly referenced and should be. Moreover, the structure of the NIH Guidelines that clearly defines categories of research and the approval required for each should be considered for the Policy. These categories for research provide concrete examples for researchers when determining the type of research they are conducting and guidance for biosafety professionals and IBCs when reviewing and approving such research.

While it can be generally agreed upon by biosafety professionals that the NIH Guidelines needed to be reconsidered, one major benefit to the aged document is the iterative process of defining and redefining research categories. This process has occurred throughout the lifetime of the document and is thanks to diligent, considerate, and critical researchers and biosafety professionals. In contrast, this Policy significantly lacks the clarity of research categories that the current NIH Guidelines provides. Each section of research that is covered in Section IV of this document needs to provide concrete examples of the categories to ensure appropriate and consistent application. Consistency of application is of critical importance to ensure overall compliance and reduce confusion among research staff and research programs writ large.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Hematology and iron metabolism

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: In the "General Definitions" section of NOT-OD-26-112, the document describes the transient expression of nucleic acids that “can be transcribed or translated” as a genetic modification. By definition this is incorrect and the transient expression from nucleic acids does not alter or modify the underlying genetics of the organism which hosts it. This definition would greatly impact the use of any transient gene expression system. This would limit the use of plasmid expression systems in yeast, bacteria or mammalian cells, morpholinos in zerba fish, or any mRNA delivery systems based on nanoparticles. All are routinely employed in most molecular laboratories with essentially no risk to researchers or the general public.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious diseases and microbiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The hazard-based scope is the right direction to provide practical and science-based institutional oversight, but the operative sentence is ambiguous: it is not clear whether the “known or potential risk to human health” condition qualifies each of the four enumerated categories or stands as an independent heading. Read the second way, the policy captures every genetically modified laboratory strain and transgenic rodent line. The two readings differ in institutional registration volume by roughly an order of magnitude. No exemption appendix replaces Section III-F and Appendix C. Four definitions over-capture generally low-risk experiments or leaves gaps: genetic modification reaches transient transfection, mRNA delivery, chemical mutagenesis and serial passage; toxin has no potency threshold and, being limited to proteins and peptides, excludes the non-proteinaceous Select Agent toxins the policy cross-references; zoonotic and novel are drafted so broadly that Section IV-1 federal review appears to capture routine work. Inadvertent gaps: large-scale containment (Appendix K) has no successor, leaving pilot-scale and manufacturing work with Risk Group 2 organisms unaddressed; deliberate environmental release is excluded from “laboratory research,” so the gene drive release decision falls outside the framework the policy otherwise builds for gene drives; and plant and arthropod containment (Appendices P and Q) end without replacement. The “institution” is also undefined, which matters for academic medical centers comprising several legal entities. An additional question stems from the statement that "Biological agent inventory and security issues [at BSL-3/ABSL-3] that may have public health consequences" must be reported to the NIH; does this imply that there will be federally mandated material inventories for research at biosafety level 3? And if yes, which will be the agency/mechanisms for oversight?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The three-tier structure is sound in principle; two placements invert it in practice. Primary cells and tissues that may carry adventitious agents are assigned to convened IBC review, moving the highest-volume, lowest-risk activity in an academic medical center into the most resource-intensive tier, while genetically modified Risk Group 1 work receives delegated review. Synthetically generated self-aggregating proteins are likewise placed in convened review alongside infectious prions, with no distinction drawn between them. We recommend moving both to delegated review. The policy also states that it removes administrative burden, but its lowest tier still requires prospective approval: there is no successor to Section III-E

notification or Section III-F exemption, so the total number of approvals rises even before the scope expansion is counted. We recommend restoring a notification tier. At the federal tier, Section IV-1 triggers are unbounded by the zoonotic and novel definitions, and NIH's reciprocal obligation carries no determination deadline, deemed-approval provision, or interim containment pathway. We recommend a 45-day determination with a written interim response, and permission to proceed at the IBC-assessed level where that period lapses and the assessment supports BSL-3 or lower. Criteria are also needed for when a published containment-reduction determination may be relied on, since misjudging equivalence is itself a reportable violation.

3. Continued utility of Risk Groups: Risk Groups remain useful and should be retained, including for genetically modified agents, where the parent agent's classification is the correct starting point for assessing what a modification changes. Risk Groups and Biosafety Levels answer different questions and neither substitutes for the other: the former describes the agent, the latter the containment appropriate to a specific manipulation. Our substantive concern is placement, not utility. Relocating the Risk Group listing from Appendix B into non-binding implementation resources removes the foundation on which the entire Section IV tiering rests, including the jurisdictional threshold, since wild-type Risk Group 1 work is outside the policy altogether. Section V-A compounds this by providing that absence from the listing does not imply Risk Group 1 classification, which makes classification an institutional judgment with no authoritative list behind it and no appeal. We recommend retaining the Risk Group listing as an appendix to the policy, with a published amendment process including notice and comment. We also suggest the idea of a federally maintained online database for Risk Groups, modeled on the current ABSA database. Deferring containment practice to the BMBL raises a parallel concern: a document written as non-regulatory guidance would carry mandatory obligations that change whenever CDC and NIH revise it.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary adoption depends on making the framework usable without an Assurance. Several of the policy's essential resources are currently tied to covered status: the Risk Group listing, NIH containment determinations for emerging and novel agents, and the published record of approved containment reductions. These should be openly available, since an unaffiliated institution cannot apply the framework without them, and a published determination benefits everyone who reads it. Three further mechanisms would help. First, a scaled model for smaller entities, including an express mechanism for shared or regional IBCs, since an independent institute or small company cannot assemble a five-member committee with two unaffiliated members. Second, access to the National Biosafety Data and Safety Analysis Center for non-covered entities, which is where voluntary participation produces the most public benefit, and which requires confidentiality protection on the model of patient safety work product before any institution's counsel will permit submission. Third, harmonization with ISO 35001 and ABSA credentialing so that voluntary adopters can demonstrate conformity through instruments they already use. We would caution against public posting as a condition of voluntary participation; it is the provision most likely to deter adoption. We would also note that the policy's extension to non-NIH-funded research at NIH-funded institutions is compliance by institutional association rather than voluntary compliance, and should not be counted as the latter.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Both templates are well constructed, and the redaction guidance in each is more developed than the policy text suggests; the policy itself should cross-reference it. Our concerns are specific.

Incident Reporting Template. The instruction to omit individual names and specific rooms is appropriate, but the combination of fields that must appear defeats de-identification in small groups: the named principal investigator, the full agent name and construct, the incident date, the position title of the person involved, training dates, and any injury, medical surveillance or treatment provided. In a five-person laboratory this is individually identifiable employee health information on a public webpage, engaging confidentiality obligations under the Americans with Disabilities Act, state occupational health and workers' compensation law, and HIPAA where occupational health sits within a covered entity. We recommend that the public version omit treatment and medical surveillance detail, reporting only whether an exposure resulted in illness, with the full detail supplied to NIH but not posted. Relatedly, the instruction that agents including Select Agents may not be redacted, combined with a named principal investigator and a containment-failure narrative, creates a biosecurity exposure that warrants a mechanism to seek NIH concurrence on withholding. The requirement that root cause analysis and corrective actions be posted publicly will shape what institutions are willing to write; we recommend considering a protection analogous to peer review or patient safety work product. The "failure to obtain or maintain IBC approval" checkbox routes administrative lapses through the same 24-hour channel and public posting as laboratory-acquired infections, which will discourage self-auditing; we recommend an annual summary for these instead, and in any case a field recording whether the institution identified the issue through its own monitoring. Finally, the prohibition on attachments limits the ability to provide supporting context, and the requirement that every field be completed in every final report should accommodate genuine non-applicability beyond a "not applicable" entry.
Meeting Minutes Template. The structure is workable and the allowance that delegated approvals may be attached as a list is helpful and should be carried into the policy text, which currently requires them to be reported in full. Three points to consider: 1) The background section states that posting applies to meetings on or after 1 June 2025, which appears to be carried over from the current transparency notice and should be restated by reference to the new policy's effective date. 2) The template recommends that quorum include at least one non-affiliated member, and leaves quorum itself to institutional policy; both the recommendation and a minimum quorum definition belong in the policy, since the template has no independent force and institutional variation on this point undermines the consistency the policy seeks. 3) The instruction that IBC member names may not be redacted, combined with the Assurance requirement for a continuously updated public roster, will make recruitment and retention of unaffiliated community members materially harder; we recommend publishing composition by role and expertise with named contacts limited to the Chair, the IBC Contact and the Biological Safety Officer.

6. Other feedback relevant to this resource: First and most important, the new policy needs a transition rule. The policy takes effect six months after publication and applies on that date to existing awards, ongoing intramural studies and all non-NIH-funded research at covered institutions, with no grandfathering. On the effective date an institution must simultaneously hold an approved Assurance, have converted a legacy registration portfolio to a three-year de novo cycle that does not currently exist, and have prospectively approved every newly in-scope activity. Anything not approved is being conducted without required approval, which the policy makes a reportable and publicly posted violation. We recommend a phased 24-month transition, with existing approvals remaining valid until scheduled conversion and an express provision that a pending conversion is not a compliance violation. Second, the Assurance itself: we need more guidance on the application, a review period, renewal continuity, the rule for multi-component institutions, and the treatment of externally administered IBCs including which entity bears the posting obligation. Will a template for Biosafety Assurance be provided and when?

Third, the Risk Group appendix and equivalence criteria for published containment determinations should be provided. Fourth, the new policy needs an express statement of the interface with the July 2026 USG Policy for Stopping High-Risk Life Sciences Research: which body screens first, whether IBC approval may issue before Institutional Review Entity classification, how referrals pass in both directions, and whether the deliberate transfer of drug resistance traits and the cloning of high-potency toxin genes, previously covered by Sections III-A and III-B-1, remain subject to heightened review under either framework. Fifth, the US Government should provide guidance on occupational health commensurate with the containment levels in use, since laboratory-acquired infection is the central reportable event while the policy imposes no affirmative occupational health requirement of its own. Sixth, we need more clarity on the limits of IBC purview for the risk assessment of clinical research when those risk are already covered by other mechanisms based on universal precautions. Finally, the other-agency provision in Section II should be rewritten to state that this policy's requirements apply in addition to, rather than in substitution for, those of other federal agencies; as drafted it reads as exempting Select Agent and FDA-regulated research, contradicting Section IV-2.

I am responding: On behalf of myself

Name: Brian H Davison

Name of Organization: ORNL

Type of Organization: Other

Type of Organization - Other: DOE national Laboratory

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): biotechnology research and development in energy, industry, and environment

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The addition of biohazard review is broadly good. My institution already did this under contract rules, best practices and BMBL. this specifies biomedical biohazards. where do environmental or industrial biotechnology hazards come into view in this definition.
There is conflicting guidance with BMBL and APHIS on BSL1/2 practices etc. (they are close but not identical; there are too many differences to list).
Plant work is no longer covered. Recombinant work in plants should still be reviewed. there is not another community standard for transgenic plant research such as the BMBL.
This expands the remit but not always authority of the IBC.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I have Deep concern on the review of ALL proposals : especially as there are not clear statements on the level of review required. or how to enact this with appropriate triage. For example, can the PI certify that it is BSL1 and therefore “exempt” and thus no further review is required? Most every PROPOSAL have an independent review by the someone - such as the IBC or designee?
The “extra” new reviews and documentation will increase regulation and oversight and overhead with minimal improvement in biosafety. this is contrary to to OSTP report on "Science a new golden age" July 2026.

It is positive that IBC approval is required for lowering the containment for wild type or genetically modified RG2 biological agents. [This affirms our practice in using a graded approach that we have used for extremely small volumes and samples which are always under containment]

Limit NIH preapproval to defined high-risk or genuinely novel circumstances and allow local IBCs to rely on published NIH precedents.

Another positive is that “delegated review is now permitted for specific classes”

3. Continued utility of Risk Groups: RGs should remain the baseline for risk assessment. Then the BSL are used to contain and perform the work under a GRADED approach as outlined in the BMBL.

The extra review by NIH of “unknowns" will be onerous IF applied to environmental research. For example, the soil microbiome might contain pathogens but usually not and the direct risk is low. we have instituted checks to pause work if a pathogen is discovered during environmental isolation and cultivation.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): na

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: the policy is unclear on de minimus incident reporting. eg. Would the incident reporting be required for a needlestick of RG1 or BSL1 work where a nonspecific prophylactic antibiotic was administered as part of basic first aid and followed by monitoring? [non-agent specific treatment]. in the meeting template:
the public disclosure of biohazards and the naming of the PI publicly could comprise the worker identity safety outside of work. it may also compromise the awareness from adversaries under classified or export control regulations. There should be a mode for expurgated declassified release which allows the broad biosafety assessment with a declassified description and a redacted PI.

6. Other feedback relevant to this resource: there needs to be a phased implementations with changes based on this implementation pilot.
the cost of implementation should be considered. especially in the review of ALL proposals.

Uploaded File: Comments-NIH-Draft-Biosafety-Policy-for-Research-Involving-Biohazards.docx

Docket ID: NOT-OD-26-112)
Title: NIH Draft Biosafety Policy for Research Involving Biohazards
Submitter/Category: Citizen Advocate

As a former NIH employee and now a concerned citizen advocate, I would like to make the following suggestions and comments on the proposed Biosafety Policy for Research Involving Biohazards.

We know that biosafety oversight works best when it directs attention and resources toward the activities that present meaningful risk. Transparency and accountability are important for everyone, but these actions must be done in a way that preserves researcher safety, encourages reporting, protects valuable research, and allows institutions to focus their oversight where it matters most.

Public Posting
If public posting remains part of the final policy, it should request anonymized, aggregated reporting, with identifiable information disclosed only when there is a legitimate need to know, such as during a public health investigation. The necessary recordkeeping needs to establish a clear baseline retention period and clarify how longer grant-specific requirements should apply when IBC registrations cover multiple projects or funding sources.

Reporting Thresholds
Establish reporting thresholds and clear up overlapping definitions between federal agencies so institutions aren't confused by duplicate or conflicting reporting rules.

Timeline
It would be helpful to provide a phased transition. Specifically, a minimum 24-month phased implementation period alongside pilot tests for new reporting and meeting-minute templates.

Additionally, to ensure these changes do not adversely impact the pursuit of research, it would be helpful to release a revised draft for public review before issuing a final policy.

Compliance Costs
Compliance costs will need to be addressed. Smaller colleges and non-R1 Research institutions with limited EHS/biosafety staff will potentially incur financial and operational constraints and will need guidance and resources.

Please consider how all these new requirements could affect scientists and their pursuit of medical progress, their institutions, and the conduct of biomedical research in the US.

Thank you for the opportunity to comment.
Kim Westervelt

434. Engineering Biology Research Consortium

I am responding: On behalf of an organization

Name: Rodney Eric Williams

Name of Organization: Engineering Biology Research Consortium

Type of Organization: Professional Organization/Association

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Synthetic and Engineering Biology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: EBRC supports expanding NIH's biosafety policy beyond research involving recombinant or synthetic nucleic acid molecules to encompass a broader range of biological research that may involve biohazards. However, a broader scope need not create broader administrative requirements or ambiguous oversight frameworks. Clear definitions and decision criteria will be essential to ensure institutions can consistently determine which research activities fall within scope and what level of oversight is warranted. Without clear boundaries and predictable criteria, the expanded scope could create uncertainty about which activities require oversight. This uncertainty may discourage institutions from pursuing otherwise appropriate research and have a chilling effect on research and innovation without corresponding improvements in biosafety.

The expansion of scope also raises questions about how this policy will interact with existing federal biosafety, biosecurity, and research oversight requirements. Depending on the research activity, biological agent, and funding source, a project may be subject to oversight and review from multiple other federal funding and oversight agencies (e.g., CDC, DHS, USDA), and the U.S. Government Policy for Stopping High-Risk Life Sciences Research. Together, these policies could significantly expand review, approval, and reporting obligations for engineering biology research, including synthetic biology, engineered biological systems, and pathogen-related research. Without clear coordination, the expanded policy could create duplicative reviews, conflicting requirements, or uncertainty about which agency's processes should be followed and in what order.

NIH should therefore:

-Provide clear definitions, decision criteria, and practical examples for determining which research activities fall within scope, particularly those involving genetically modified organisms, synthetic biological systems, and changes resulting from serial passaging or reassortment.

-Ensure that oversight requirements reflect meaningful biosafety risks rather than the presence of a

particular biological material or modification alone, and exempt or streamline requirements for well-characterized, low-risk research where additional oversight offers little-to-no safety benefit.

-Clarify how the policy applies to emerging or engineered biological systems that do not fit established definitions or classifications, including how institutions should determine whether the research falls within scope when there is no clear precedent.

-Clarify which activities at NIH-funded institutions are covered when the research itself is not NIH-funded, including how institutions should identify covered activities without creating unnecessary compliance obligations for unrelated research.

-Clarify how the policy interacts with biosafety, biosecurity, and research oversight requirements imposed by other federal agencies, including how overlapping or potentially conflicting requirements will be reconciled when research is subject to multiple federal policies or funding conditions.

-Specifically clarify the relationship between this policy and the U.S. Government Policy for Stopping High-Risk Life Sciences Research, including how institutions should determine which requirements apply when research falls within the scope of both policies and how to navigate their respective review, approval, and compliance processes.

A broader policy can strengthen biosafety, but its reach must be justified, clearly defined, and proportionate to risk. NIH must ensure that expanded coverage delivers meaningful safety benefits without unnecessarily extending institutional compliance obligations.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed framework establishes distinct roles for NIH, institutions, IBCs, and investigators, with different levels of review based on the nature and risk of the research. Its effectiveness will depend on whether these responsibilities are clearly defined, oversight is proportionate to risk, and accountability measures promote biosafety without creating unnecessary administrative burden. Delegated review is an important part of this balance, allowing IBCs to focus their time and expertise on higher-risk or more uncertain research rather than routine activities that can be assessed against established criteria. Ultimately, the framework should direct oversight resources where they can meaningfully reduce risk, rather than add procedural requirements that do not improve biosafety.

NIH should therefore:

-Clearly define the circumstances that warrant NIH review and explain what specific or additional safety benefit NIH-level review is intended to provide beyond institutional assessment.

-Establish clear criteria that support predictable escalation decisions without requiring NIH review solely because a system is novel or its risk profile is not fully characterized.

-Preserve flexibility for institutions to delegate review of routine, well-characterized, low-risk activities beyond the specific categories enumerated in the policy, using predefined criteria and clear escalation pathways when risks or uncertainties warrant full IBC review.

-Establish predictable timelines for federal review–including target timelines for initial review, any requests for additional information, and final decisions–along with a process for communicating delays and resolving stalled reviews.

-Ensure that documentation, public reporting, and incident-reporting requirements are proportionate to risk, clearly defined, and consistently applied, with appropriate protections for confidential, proprietary, and security-sensitive information.

-Coordinate NIH requirements with existing institutional biosafety, research compliance, and incident-reporting processes to minimize duplicative administrative work for institutions and investigators.

-Ensure that NIH review and approval requirements account for existing oversight by other federal agencies, avoiding duplicative review, inconsistent requirements, and unnecessary delays where research activities or risks are already subject to other federal oversight.
- For example, clarify how NIH review under this draft policy for changes involving the risk group or safety level classification of biohazards should interact with ITPRB review under the U.S. Government Policy for Stopping High-Risk Life Sciences Research.

-Evaluate the policy's implementation by collecting data on IBC workload, review timelines, institutional resources, reporting burden, and effects on research timelines and activity, and use those findings to revise requirements and oversight levels that impose burdens disproportionate to their biosafety benefits.

A successful, tiered framework must strengthen accountability while directing oversight resources where they can have the greatest impact. Clear responsibilities, proportionate reporting requirements, timely review, and flexibility for delegated review will help institutions maintain effective biosafety programs without unnecessarily delaying responsible research.

3. Continued utility of Risk Groups: The draft appropriately recognizes that Risk Group and Biosafety Level classifications are related but not equivalent and that containment decisions must account for the specific research being conducted. However, additional guidance is needed to clarify how the different factors identified in this policy should be weighed when assessing genetically modified and synthetic biological systems – particularly when modifications alter the characteristics of a parent agent or when established classifications provide limited information about a novel system.

NIH should therefore:

-Provide practical criteria and examples for determining how RG classifications, genetic modifications, and experimental manipulations should inform containment decisions. In particular, clarify how investigators and IBCs should weigh factors such as changes in pathogenicity, transmissibility, host range, and toxicity when these factors do not point to a consistent risk determination.

-Establish clear expectations for the supporting evidence and documentation investigators and IBCs must provide to justify risk assessments and resulting containment decisions to ensure efficient, transparent,

and consistent review processes.

-Clarify how experiment-specific approvals to lower containment differ from revisions to an agent's RG classification. NIH should provide guidance on how to document and communicate these distinct determinations so that approval to handle a specific attenuated strain at a lower BSL is not misinterpreted as changing the agent's RG classification.

-Clarify how the policy's minimum containment requirements interact with provisions for lower-containment determinations. Section V-E establishes a minimum of BSL-2 for research involving GDMOs, while Sections III-B and IV-1 provide for NIH review of initial requests to lower containment below BSL-2 for GDMOs and to lower containment for RG3/RG4 agents. NIH should clarify the criteria for evaluating these requests, including how evidence of attenuation or loss of function and other risk-reducing modifications should inform containment decisions, and explain how these provisions interact with the policy's stated minimum containment requirements.

-Provide additional guidance for risk assessment of synthetic and engineered biological systems that combine sequences from multiple sources or do not fit readily within established RG classifications. Section V-C identifies source RG classifications, the percentage of the genome contributed by each source, encoded functions, and potential synergistic effects as relevant considerations. NIH should clarify:
-How these factors should be weighed when they suggest different levels of risk;
-How the assumption that sequences will encode functions as they did in their original host should be applied alongside consideration of their effects in a new biological context, including potentially unexpected or synergistic effects; and
-What evidence and documentation are needed to characterize and assess uncertainty in the resulting system's risk profile.

Clearer criteria for weighing risk factors, interpreting minimum containment requirements, and determining when federal review is necessary would help institutions apply the policy consistently while preserving experiment-specific scientific judgment. NIH should focus additional review on cases where it provides meaningful value in addressing risk or uncertainty, rather than relying on classifications alone to determine the appropriate level of containment or oversight.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Strengthening biosafety requires a shared commitment across the research ecosystem. The draft policy has the potential to advance this goal, but its effectiveness will depend in part on whether institutions and researchers are encouraged to report concerns, learn from safety events, and address deficiencies in good-faith. EBRC encourages NIH to pair clear expectations and appropriate accountability with safeguards that promote transparency, trust, and continuous improvement.

NIH should consider approaches that:

-Prioritize corrective action, technical assistance, and learning over punitive measures for accidents or inadvertent noncompliance.

Establish clear criteria for escalating responses to intentional or reckless violations, repeated noncompliance, or failure to take timely and adequate corrective action.

-Clarify institutional and Biological Safety Officer (BSO) responsibilities to promote accountability without unfairly assigning individual blame for broader institutional failures.

-Ensure incident reporting and public-posting requirements promote transparency and shared learning while protecting personal, proprietary, and security-sensitive information.

-Provide clear, consistent redaction criteria for public reporting requirements and safeguards against unnecessarily exposing sensitive research, personnel, or institutional reputations in ways that could discourage good-faith incident reporting.

-Recognize the proposed National Biosafety Data and Safety Analysis Center (NBDSAC) as an opportunity to promote shared learning from incidents, near-misses, and other safety events. Good-faith reporting should support prevention and continuous improvement, not become a basis for punitive identification of institutions or individuals.

-Contribute to coordination across federal agencies and oversight frameworks, including clearer guidance on the relationship between biosafety and biosecurity requirements, to reduce fragmented or duplicative obligations and support consistent biosafety practices.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft IBC meeting-minutes and incident-reporting templates will shape how institutions document committee decisions and report biosafety incidents. The templates should provide clear instructions and allow institutions to meet these requirements without unnecessary or duplicative documentation.

NIH should therefore:

-Revise the draft IBC meeting-minutes and incident-reporting templates in response to stakeholder feedback.

-Establish clear mechanisms and processes for initial and final reports, the submission of supplemental information, and consistent redaction of personal, proprietary, and security-sensitive information before public posting.

-Clarify the safeguards governing the use of reported information about principal investigators (PIs), ensuring that it is used to promote biosafety and address substantiated concerns rather than as a basis for unwarranted punitive action.

-Clearly define the minimum documentation needed to record IBC deliberations and decisions.

-Allow cross-referencing of existing institutional records where appropriate to avoid duplicative documentation.

-Clarify the intended start date for the meeting-minutes public-posting requirement, including its relationship to the policy's effective date, and provide consistent criteria for redacting personal, proprietary, and security-sensitive information.

6. Other feedback relevant to this resource: Effective implementation will require clear guidance on the policy's requirements and how institutions are expected to apply them in practice. The draft policy introduces expanded biosafety oversight and detailed documentation, public posting, and incident-reporting requirements. For this policy to be effective and beneficial, NIH must provide practical support to help institutions interpret these requirements consistently, assess and plan for staffing and expertise needed for implementation, and avoid unnecessary administrative burden.

NIH should therefore:

-Solicit stakeholder feedback on draft implementation materials, including guidance, decision trees, and reporting and documentation templates. NIH should publish draft materials promptly after finalizing the policy, allow at least 30 days for feedback, and summarize how substantive comments were addressed in the final materials.

-Develop practical decision trees and examples showing which research activities are covered, which oversight tier applies, when NIH approval is required, when delegated review is appropriate, and how genetically modified and synthetic biological systems should be evaluated.
-Examples should address both straightforward cases and situations in which the scope, risk classification, or appropriate containment level is uncertain.

-Provide a crosswalk from the current NIH Guidelines to the new policy, identifying requirements that are retained, modified, eliminated, or newly introduced, and explaining how existing institutional processes should be adapted.
-The crosswalk should specifically identify new institutional obligations, including public posting, record retention, and incident reporting.

-Maintain the draft policy's six-month transition period, with final implementation guidance, decision trees, crosswalks, and templates available at least 90 days before the effective date. If NIH cannot meet that timeline, it should extend the effective date as needed to preserve a meaningful period for institutional preparation.

-Establish a six-month grace period after the effective date for good-faith administrative deficiencies arising from new documentation, public-posting, and procedural requirements. During this period, NIH should prioritize technical assistance and corrective action over enforcement, while maintaining substantive biosafety, prior-approval, and incident-reporting requirements.

-Establish clear timelines for NIH review, including target timeframes for acknowledging requests, identifying missing information, and issuing decisions.
For example, NIH could aim to acknowledge submissions within 10 business days and provide an initial determination or a timeline for resolution within 60 calendar days of receiving a complete submission.
-NIH should explain how delays will be communicated and provide points of contact for questions and

unresolved cases.

-Request that OSTP establish an interagency working group, or use an existing interagency forum, with relevant federal agencies to develop aligned implementation guidance and clarify how this policy interacts with other biosafety, biosecurity, and incident-reporting requirements.
-The group should identify conflicting or duplicative obligations, coordinate relevant definitions and reporting expectations, and communicate agreed-upon approaches to institutions.

-Include a cross-agency policy crosswalk in the implementation materials to help institutions determine which requirements apply based on the research activity, biological agent, and relevant funding or oversight arrangements.

-Review implementation after the first year and publish a summary of feedback and operational data, including review timelines, institutional workload, recurring interpretation questions, and challenges with documentation and reporting.
-NIH should use these findings to clarify guidance and adjust implementation where requirements create burdens disproportionate to their biosafety benefits.

Successful implementation will depend on more than publication of the final policy. Timely guidance, a meaningful opportunity for stakeholder feedback, predictable review timelines, and a proportionate transition to new administrative requirements will help institutions apply the policy consistently while maintaining effective biosafety oversight.

Description: Full official EBRC response, including an organizational overview and an introductory position statement, on organizational letterhead

EBRC Engineering Biology Research Consortium

Response to NIH Request for Information on
Draft NIH Biosafety Policy for Research Involving Biohazards

Notice Number: NOT-OD-26-1120

19 October 2026

The Engineering Biology Research Consortium (EBRC) is a nonprofit, public-private partnership that brings together scientists, engineers, and industry leaders to advance the field of engineering biology to address national and global needs. EBRC's members include experts from over 100 universities and research institutes, alongside leaders from more than 30 companies, philanthropies, and other organizations. Working closely with partners across the engineering biology ecosystem, EBRC focuses on four key areas: Research Roadmapping, Policy & International Engagement, Education, and Security.

EBRC welcomes the opportunity to respond to the National Institutes of Health (NIH) Request for Information on its Draft NIH Biosafety Policy for Research Involving Biohazards. EBRC supports modernizing biosafety oversight to address the breadth of contemporary biomedical research, including genetically modified organisms, synthetic biological systems, and emerging engineering biology technologies. Given the diversity of biological systems, modifications, and research applications, an effective policy should establish clear definitions, risk-proportionate oversight, transparent institutional responsibilities, and practical implementation guidance while avoiding unnecessary administrative burden, duplicative review, and delays that do not meaningfully improve biosafety. EBRC encourages NIH to implement a clear, flexible, and risk-based framework that strengthens biosafety practices, promotes accountability and evidence-based learning, and supports rigorous, innovative, and responsible research.

1. Appropriateness of Scope of New Policy

EBRC supports expanding NIH's biosafety policy beyond research involving recombinant or synthetic nucleic acid molecules to encompass a broader range of biological research that may involve biohazards. However, a broader scope need not create broader administrative requirements or ambiguous oversight frameworks. Clear definitions and decision criteria will be essential to ensure institutions can consistently determine which research activities fall within scope and what level of oversight is warranted. Without clear boundaries and predictable criteria, the expanded scope could create uncertainty about which activities require oversight. This uncertainty may discourage institutions from pursuing otherwise appropriate research and have a chilling effect on research and innovation without corresponding improvements in biosafety.

The expansion of scope also raises questions about how this policy will interact with existing federal biosafety, biosecurity, and research oversight requirements. Depending on the research activity, biological agent, and funding source, a project may be subject to oversight and review from multiple other federal funding and oversight agencies (e.g., CDC, DHS, USDA), and the U.S.

Government Policy for Stopping High-Risk Life Sciences Research. Together, these policies could significantly expand review, approval, and reporting obligations for engineering biology research, including synthetic biology, engineered biological systems, and pathogen-related research. Without clear coordination, the expanded policy could create duplicative reviews, conflicting requirements, or uncertainty about which agency's processes should be followed and in what order.

NIH should therefore:

- Provide clear definitions, decision criteria, and practical examples for determining which research activities fall within scope, particularly those involving genetically modified organisms, synthetic biological systems, and changes resulting from serial passaging or reassortment.
- Ensure that oversight requirements reflect meaningful biosafety risks rather than the presence of a particular biological material or modification alone, and exempt or streamline requirements for well-characterized, low-risk research where additional oversight offers little-to-no safety benefit.
- Clarify how the policy applies to emerging or engineered biological systems that do not fit established definitions or classifications, including how institutions should determine whether the research falls within scope when there is no clear precedent.
- Clarify which activities at NIH-funded institutions are covered when the research itself is not NIH-funded, including how institutions should identify covered activities without creating unnecessary compliance obligations for unrelated research.
- Clarify how the policy interacts with biosafety, biosecurity, and research oversight requirements imposed by other federal agencies, including how overlapping or potentially conflicting requirements will be reconciled when research is subject to multiple federal policies or funding conditions.
- Specifically clarify the relationship between this policy and the U.S. Government Policy for Stopping High-Risk Life Sciences Research, including how institutions should determine which requirements apply when research falls within the scope of both policies and how to navigate their respective review, approval, and compliance processes.

A broader policy can strengthen biosafety, but its reach must be justified, clearly defined, and proportionate to risk. NIH must ensure that expanded coverage delivers meaningful safety benefits without unnecessarily extending institutional compliance obligations.

2. Appropriateness of Tiered Oversight & Calibration to Risks

The proposed framework establishes distinct roles for NIH, institutions, IBCs, and investigators, with different levels of review based on the nature and risk of the research. Its effectiveness will depend on whether these responsibilities are clearly defined, oversight is proportionate to risk, and accountability measures promote biosafety without creating unnecessary administrative

burden. Delegated review is an important part of this balance, allowing IBCs to focus their time and expertise on higher-risk or more uncertain research rather than routine activities that can be assessed against established criteria. Ultimately, the framework should direct oversight resources where they can meaningfully reduce risk, rather than add procedural requirements that do not improve biosafety.

NIH should therefore:

- Clearly define the circumstances that warrant NIH review and explain what specific or additional safety benefit NIH-level review is intended to provide beyond institutional assessment.
- Establish clear criteria that support predictable escalation decisions without requiring NIH review solely because a system is novel or its risk profile is not fully characterized.
- Preserve flexibility for institutions to delegate review of routine, well-characterized, low-risk activities beyond the specific categories enumerated in the policy, using predefined criteria and clear escalation pathways when risks or uncertainties warrant full IBC review.
- Establish predictable timelines for federal review–including target timelines for initial review, any requests for additional information, and final decisions–along with a process for communicating delays and resolving stalled reviews.
- Ensure that documentation, public reporting, and incident-reporting requirements are proportionate to risk, clearly defined, and consistently applied, with appropriate protections for confidential, proprietary, and security-sensitive information.
- Coordinate NIH requirements with existing institutional biosafety, research compliance, and incident-reporting processes to minimize duplicative administrative work for institutions and investigators.
- Ensure that NIH review and approval requirements account for existing oversight by other federal agencies, avoiding duplicative review, inconsistent requirements, and unnecessary delays where research activities or risks are already subject to other federal oversight.
    - For example, clarify how NIH review under this draft policy for changes involving the risk group or safety level classification of biohazards should interact with ITPRB review under the U.S. Government Policy for Stopping High-Risk Life Sciences Research.
- Evaluate the policy's implementation by collecting data on IBC workload, review timelines, institutional resources, reporting burden, and effects on research timelines and activity, and use those findings to revise requirements and oversight levels that impose burdens disproportionate to their biosafety benefits.

A successful, tiered framework must strengthen accountability while directing oversight resources where they can have the greatest impact. Clear responsibilities, proportionate reporting requirements, timely review, and flexibility for delegated review will help institutions maintain effective biosafety programs without unnecessarily delaying responsible research.

3. Risk Groups, Biosafety Levels, and Risk Assessment

The draft appropriately recognizes that Risk Group and Biosafety Level classifications are related but not equivalent and that containment decisions must account for the specific research being conducted. However, additional guidance is needed to clarify how the different factors identified in this policy should be weighed when assessing genetically modified and synthetic biological systems – particularly when modifications alter the characteristics of a parent agent or when established classifications provide limited information about a novel system.

NIH should therefore:

- Provide practical criteria and examples for determining how RG classifications, genetic modifications, and experimental manipulations should inform containment decisions. In particular, clarify how investigators and IBCs should weigh factors such as changes in pathogenicity, transmissibility, host range, and toxicity when these factors do not point to a consistent risk determination.
- Establish clear expectations for the supporting evidence and documentation investigators and IBCs must provide to justify risk assessments and resulting containment decisions to ensure efficient, transparent, and consistent review processes.
- Clarify how experiment-specific approvals to lower containment differ from revisions to an agent's RG classification. NIH should provide guidance on how to document and communicate these distinct determinations so that approval to handle a specific attenuated strain at a lower BSL is not misinterpreted as changing the agent's RG classification.
- Clarify how the policy's minimum containment requirements interact with provisions for lower-containment determinations. Section V-E establishes a minimum of BSL-2 for research involving GDMOs, while Sections III-B and IV-1 provide for NIH review of initial requests to lower containment below BSL-2 for GDMOs and to lower containment for RG3/RG4 agents. NIH should clarify the criteria for evaluating these requests, including how evidence of attenuation or loss of function and other risk-reducing modifications should inform containment decisions, and explain how these provisions interact with the policy's stated minimum containment requirements.
- Provide additional guidance for risk assessment of synthetic and engineered biological systems that combine sequences from multiple sources or do not fit readily within established RG classifications. Section V-C identifies source RG classifications, the percentage of the genome contributed by each source, encoded functions, and potential synergistic effects as relevant considerations. NIH should clarify:
    - How these factors should be weighed when they suggest different levels of risk;
    - How the assumption that sequences will encode functions as they did in their original host should be applied alongside consideration of their effects in a new biological context, including potentially unexpected or synergistic effects; and

- What evidence and documentation are needed to characterize and assess uncertainty in the resulting system's risk profile.

Clearer criteria for weighing risk factors, interpreting minimum containment requirements, and determining when federal review is necessary would help institutions apply the policy consistently while preserving experiment-specific scientific judgment. NIH should focus additional review on cases where it provides meaningful value in addressing risk or uncertainty, rather than relying on classifications alone to determine the appropriate level of containment or oversight.

4. Voluntary Compliance and Strengthening the Broader Biosafety Ecosystem

Strengthening biosafety requires a shared commitment across the research ecosystem. The draft policy has the potential to advance this goal, but its effectiveness will depend in part on whether institutions and researchers are encouraged to report concerns, learn from safety events, and address deficiencies in good-faith. EBRC encourages NIH to pair clear expectations and appropriate accountability with safeguards that promote transparency, trust, and continuous improvement.

NIH should consider approaches that:

- Prioritize corrective action, technical assistance, and learning over punitive measures for accidents or inadvertent noncompliance.
- Establish clear criteria for escalating responses to intentional or reckless violations, repeated noncompliance, or failure to take timely and adequate corrective action.
- Clarify institutional and Biological Safety Officer (BSO) responsibilities to promote accountability without unfairly assigning individual blame for broader institutional failures.
- Ensure incident reporting and public-posting requirements promote transparency and shared learning while protecting personal, proprietary, and security-sensitive information.
- Provide clear, consistent redaction criteria for public reporting requirements and safeguards against unnecessarily exposing sensitive research, personnel, or institutional reputations in ways that could discourage good-faith incident reporting.
- Recognize the proposed National Biosafety Data and Safety Analysis Center (NBDSAC) as an opportunity to promote shared learning from incidents, near-misses, and other safety events. Good-faith reporting should support prevention and continuous improvement, not become a basis for punitive identification of institutions or individuals.
- Contribute to coordination across federal agencies and oversight frameworks, including clearer guidance on the relationship between biosafety and biosecurity requirements, to reduce fragmented or duplicative obligations and support consistent biosafety practices.

5. Draft Incident Reporting and Draft Meeting Minutes Templates

The draft IBC meeting-minutes and incident-reporting templates will shape how institutions document committee decisions and report biosafety incidents. The templates should provide clear instructions and allow institutions to meet these requirements without unnecessary or duplicative documentation.

NIH should therefore:

- Revise the draft IBC meeting-minutes and incident-reporting templates in response to stakeholder feedback.
- Establish clear mechanisms and processes for initial and final reports, the submission of supplemental information, and consistent redaction of personal, proprietary, and security-sensitive information before public posting.
- Clarify the safeguards governing the use of reported information about principal investigators (PIs), ensuring that it is used to promote biosafety and address substantiated concerns rather than as a basis for unwarranted punitive action.
- Clearly define the minimum documentation needed to record IBC deliberations and decisions.
- Allow cross-referencing of existing institutional records where appropriate to avoid duplicative documentation.
- Clarify the intended start date for the meeting-minutes public-posting requirement, including its relationship to the policy's effective date, and provide consistent criteria for redacting personal, proprietary, and security-sensitive information.

6. Implementation, Guidance, and Institutional Readiness

Effective implementation will require clear guidance on the policy's requirements and how institutions are expected to apply them in practice. The draft policy introduces expanded biosafety oversight and detailed documentation, public posting, and incident-reporting requirements. For this policy to be effective and beneficial, NIH must provide practical support to help institutions interpret these requirements consistently, assess and plan for staffing and expertise needed for implementation, and avoid unnecessary administrative burden.

NIH should therefore:

- Solicit stakeholder feedback on draft implementation materials, including guidance, decision trees, and reporting and documentation templates. NIH should publish draft materials promptly after finalizing the policy, allow at least 30 days for feedback, and summarize how substantive comments were addressed in the final materials.
- Develop practical decision trees and examples showing which research activities are covered, which oversight tier applies, when NIH approval is required, when delegated review is appropriate, and how genetically modified and synthetic biological systems should be evaluated.

    - Examples should address both straightforward cases and situations in which the scope, risk classification, or appropriate containment level is uncertain.
- Provide a crosswalk from the current NIH Guidelines to the new policy, identifying requirements that are retained, modified, eliminated, or newly introduced, and explaining how existing institutional processes should be adapted.
    - The crosswalk should specifically identify new institutional obligations, including public posting, record retention, and incident reporting.
- Maintain the draft policy's six-month transition period, with final implementation guidance, decision trees, crosswalks, and templates available at least 90 days before the effective date. If NIH cannot meet that timeline, it should extend the effective date as needed to preserve a meaningful period for institutional preparation.
- Establish a six-month grace period after the effective date for good-faith administrative deficiencies arising from new documentation, public-posting, and procedural requirements. During this period, NIH should prioritize technical assistance and corrective action over enforcement, while maintaining substantive biosafety, prior-approval, and incident-reporting requirements.
- Establish clear timelines for NIH review, including target timeframes for acknowledging requests, identifying missing information, and issuing decisions.
    - For example, NIH could aim to acknowledge submissions within 10 business days and provide an initial determination or a timeline for resolution within 60 calendar days of receiving a complete submission.
    - NIH should explain how delays will be communicated and provide points of contact for questions and unresolved cases.
- Request that OSTP establish an interagency working group, or use an existing interagency forum, with relevant federal agencies to develop aligned implementation guidance and clarify how this policy interacts with other biosafety, biosecurity, and incident-reporting requirements.
    - The group should identify conflicting or duplicative obligations, coordinate relevant definitions and reporting expectations, and communicate agreed-upon approaches to institutions.
- Include a cross-agency policy crosswalk in the implementation materials to help institutions determine which requirements apply based on the research activity, biological agent, and relevant funding or oversight arrangements.
- Review implementation after the first year and publish a summary of feedback and operational data, including review timelines, institutional workload, recurring interpretation questions, and challenges with documentation and reporting.
    - NIH should use these findings to clarify guidance and adjust implementation where requirements create burdens disproportionate to their biosafety benefits.

Successful implementation will depend on more than publication of the final policy. Timely guidance, a meaningful opportunity for stakeholder feedback, predictable review timelines, and a proportionate transition to new administrative requirements will help institutions apply the policy consistently while maintaining effective biosafety oversight.

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: What is the rational behind registering and reviewing a risk assessment for low level transgenic organisms, such as C. elegans, drosophila, murine rodents housed at ABSL-1, that can not cause human or animal disease. These all fall out of the scope of the newly proposed policy. The amount of effort to capture these vast quantities of organism and asses a risk that doesn't exist, over and over again, is a huge drain on biosafety professionals and takes away from vital support of researchers without any real benefit to safety or security. IF all organism do need to be registered at an institution receiving NIH funding, such low risk organisms as mentioned above should be captured under a blanket registration for the university.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: "Research with primary cells that may be contaminated by adventitious agents." Does this include all human cells? Under OSHA, all human cells are already considered potentially infected unless tested for a short list of BBP. But, in reality, the risk from one human cell, whether established or primary, does NOT CHANGE the risk assessment!!! Why would all human primary cells have to be registered? Some modified primary cells are in existence for a very short time (as they are unwanted outcomes and instantly destroyed) and registering them doesn't make sense for material that no longer exists. All other established human cells already have mitigation measure in place to handle them safely.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Please consider removing the need to report to NIH for failure to have IBC protocols for previously exempt experiments. It's hard enough to capture work that has risk and has to be captured for review. The need to register all transgenic mice and drosophila or all modified human cell lines does not change risk and does not increase safety. This burden to capture the material requested in this proposed policy will actually harm our researches and not provide any useful outcomes to create safer work environments! This policy

seems to be more about big brother watching rather than updating biosafety application to our researchers and lab spaces. Biosafety professionals will have less time to perform risk assessments on procedures and labs handling material. The requirements of report exposures and spills will reduce researchers reaching out to biosafety professionals for help.

6. Other feedback relevant to this resource: The cost and time of implementing the proposed guidelines with be far beyond what most institutions have available, including the staff needed to get a new program together and delivered. It takes about 2 years to generate, test, and implement a new registration platform, so the 6month time-line would not be anywhere enough.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Biosafety Professionals Are Assigned Responsibilities Without Corresponding Authority

Observation
The proposed policy substantially expands the role of biosafety professionals in inspections, incident response, reporting, consultation, and oversight activities.
However, the draft does not appear to establish corresponding authority.

Real-World Implementation Impact
In a real institution, biosafety professionals are often expected to:
• Investigate incidents;
• Identify hazards;
• Recommend corrective actions;
• Monitor compliance;
• Support IBC oversight; and
• Advise institutional leadership.

Yet the policy does not clearly specify whether they have authority to:
• Access required records;
• Enter laboratories when necessary;
• Require corrective actions;
• Escalate unresolved concerns;
• Suspend unsafe activities; or
• Elevate significant concerns beyond departmental management.
The result is an accountability mismatch.
An individual may be held responsible for identifying and addressing risks without being given sufficient authority to ensure those risks are addressed.

Why This Matters
Successful safety programs depend on clear accountability structures. Authority and responsibility should be aligned.
If biosafety professionals are expected to serve as key components of a risk-based oversight system, they should possess the authority necessary to carry out those responsibilities effectively.

Recommendation
NIH should establish clear expectations regarding:
1. Minimum authority.
2. Escalation pathways.
3. Access rights.
4. Corrective-action authority.
5. Communication with institutional leadership.
Clarifying authority would strengthen implementation and improve accountability.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The Authorized Organizational Representative Role Requires Greater Clarity

Observation
The proposed Authorized Organizational Representative (AOR) role appears to assume responsibilities that are often distributed among multiple individuals within existing research governance structures. The function and authority of the role are not fully defined.

Real-World Implementation Impact
In practice, institutions may assign the role to:
• Biosafety professionals;
• Institutional Officials;
• Research compliance leaders;
• Signing Officials;
• Vice Presidents for Research;
• Research Integrity Officers; or
• Other senior administrators.
As written, different institutions may select entirely different governance models.

This creates uncertainty regarding:
• Accountability;
• Authority;
• Reporting relationships;
• Institutional commitments; and
• Decision-making responsibilities.
Investigators, IBCs, and biosafety staff may also be unclear regarding when concerns should be elevated to the AOR.

Why This Matters
A role intended to improve accountability may instead create inconsistency if institutions interpret the position differently.
The Biosafety Assurance appears designed to represent institutional commitments. Such commitments are most effective when responsibility and authority are clearly defined.

Recommendation
NIH should provide guidance regarding:
1. Purpose of the position.
2. Required authority.
3. Reporting relationships.
4. Relationship to the IBC and biosafety program.
5. Example governance structures for different institution types.
Clear governance expectations would improve consistency across the research enterprise.

438. Texas Biomedical Research Institute

I am responding: On behalf of an organization

Name: Hsiang-Ming Wang

Name of Organization: Texas Biomedical Research Institute

Type of Organization: Non-Profit Research Organization

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious Diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed policy defines biological agents as pathogens that cause disease in humans only, excluding animals or plants. This is a narrow definition that deviates from a "One Health" approach. The Federal Select Agent Program (FSAP) provides an excellent model for cross-agency collaboration on biological hazard oversight. This proposed policy expands the scope of human pathogens but may create confusion by excluding animal and plant-specific pathogens that were included under the prior NIH Guidelines. At the same time, there should be either a coordinated sister policy that covers animal- and plant- specific pathogens or, ideally, a single comprehensive policy that covers all biological hazards affecting the health of humans, animals, and plants.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed tiered oversight linked to calibration of risk is appropriate. However, the proposed timeline for renewals may generate confusion and potential non-compliance as Institutional Biosafety Committee (IBC) protocols must be renewed every 3 years, whereas Biosafety Assurance is required every 4 years, and many NIH grants renew on a 5-year cycle. Synchronization of these timelines would streamline oversight and reduce confusion. NIH should, at a minimum, provide automated reminders for the renewal of Biosafety Assurance for registered entities.

3. Continued utility of Risk Groups: The continued use of Risk Groups is appropriate. However, what is missing is a process to ensure timely updates and publishing of "approved determinations of appropriate lower containment for research involving wild type or genetically modified RG3 or RG4 biological agents". Specifically, Appendix D of the current NIH Guidelines have not been kept up to date, resulting in inconsistencies and lack of transparency in the evaluation process and requirements for lowering containment. One solution would be to create an active database that is updated at least quarterly and contains pertinent information on specific approved conditions where lower Biosafety Level is granted for the indicated agents. This approach will reduce the administrative burden on both NIH and the regulated entities while maximizing the sharing of scientific knowledge.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Clear guidance of required information to be submitted must protect the individual and institution willing to share this information. To maximize the effectiveness, voluntary reports, including near-miss incidents, should be protected from Freedom of Information Act (FOIA) inquiries and used for shared learning instead of fault-finding.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The types of incidents that must be reported to NIH need to be better defined and described along with concrete examples. A requirement to "post all incident reports on a public facing webpage" combined with lack of clarity regarding how incidents are defined could lead to misinterpretation and extra administrative burden with no benefit in risk reduction. Moreover, to avoid double reporting, the Federally Funded Research and Development Center (FFRDC) must coordinate and synchronize data with other reporting requirements of the FSAP and the Occupational Safety and Health Administration (OSHA), including, but not limited to, a shared platform for incident reporting and/or use of a unified reporting template. The lack of inter-agency coordination results in redundant incident reporting requirements that significantly increase the administrative burden at the regulated entities.

6. Other feedback relevant to this resource: Implementation resources in the following areas should be provided
- Concrete example of each review category
- Requests for reducing biosafety level
- Incident reporting requirements and information needed for these reports
- Template/guidelines for all materials that need to be posted publicly

This is not an exhaustive list.

Role - Other: Senior Director, Institutional Partnerships & Biosafety Advisor

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Clinical research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Sabai supports the overarching aim of the draft Policy to modernize biosafety oversight so that it is transparent, adaptive, and accountable. We commend the National Institutes of Health (NIH) for several changes that, in our view, strengthen biosafety practice. First, extending the Policy beyond recombinant and synthetic nucleic acid molecules to wild type biological agents, toxins, prions, and self-aggregating proteins, and applying it to non-NIH-funded research at institutions that receive any NIH funding closes gaps in the current NIH Guidelines. Second, the risk-tiered structure of Section IV, which provides for NIH and Institutional Biosafety Committee (IBC) review of research with the greatest uncertainty, IBC review of most other research, and delegated review of lower-risk research, is well calibrated and should reduce burden where risk is low. Third, the written Biosafety Assurance approved by NIH and the standardized meeting minutes and incident reporting templates will promote accountability and consistency across institutions. Fourth, the Section V risk assessment framework, which starts from the parent agent, accounts for genetic modification and manipulations, and is harmonized with the Biosafety in Microbiological and Biomedical Laboratories (BMBL), gives IBCs a clear and defensible method for assessing risk.

The comments below address the scope of the draft Policy, with particular attention to the proposed oversight of clinical research. We offer them in good faith, with recommendations to close inadvertent gaps in oversight and to resolve ambiguities that could lead to inconsistent application and compliance.

1. We recommend that NIH adopt a standalone section on clinical research, comparable in structure and thoroughness to Section III-C of the current NIH Guidelines, in place of the abbreviated callout currently embedded within Section IV-2 of the draft policy. Clinical research is fundamentally different from laboratory research. It involves procedural risks during the preparation and administration of investigational products that are not typically found in laboratories, and it often places unique limits on how the traditional hierarchy of safety controls can be applied. This practical variability contrasts notably with the well-controlled, contained handling typically evident in most laboratory settings. As the draft

Policy itself implicitly recognizes, the appropriate scope of oversight for clinical research differs materially from that of laboratory research. A section dedicated to clinical research would give this research the level of definition and clarity that its unique risk profile warrants and would convey its importance more fully than a brief callout does.

2. The complete scope of IBC review for clinical research in draft Policy Section IV-2 is ambiguous and can be interpreted in two distinct ways. The current text does not clearly indicate which of the interpretations NIH intended. In the first interpretation, the five general categories at the start of Section IV-2 apply to laboratory research. The clinical research callout, with its sub-bullets, sets out a separate independent, and narrower, set of criteria that apply to clinical research only. Clinical research that does not fit within this limited set of criteria in the callout is not within scope of the Policy. In the second interpretation, the five general categories apply to all research (laboratory and clinical) and the callout simply adds additional criteria specific to clinical research that IBCs are asked to consider. The clinical research callout is genuinely ambiguous as to whether it operates as the exclusive, controlling basis for IBC review of clinical research, or as an additional condition layered on top of the Policy's general scope. We ask NIH to state definitively which interpretation is intended. If NIH intends the first interpretation (which is the assumption behind most of our comments that follow), we do not believe this limited level of oversight is sufficient for clinical research, for the various reasons we set out below. If NIH intends the second interpretation, we encourage NIH to state this more clearly in the final Policy. Institutions, clinical trial sponsors, and IBCs may have difficulty resolving the correct interpretation from the currently published text alone.

3. If NIH's intention was for the clinical research callout in Section IV-2 to represent the sum total of clinical research requiring IBC oversight (see first interpretation above), we encourage NIH to reconsider and revise the Policy to adopt an equivalent degree of oversight rigor for clinical research as it applies to laboratory research. Relative to the current NIH Guidelines, the draft Policy appears to disproportionately reduce the oversight of clinical research. In doing so, it risks creating a potential oversight gap and double standard between clinical research and laboratory research. As a case in point, draft Policy Section IV-2 identifies numerous categories (bullets 1-5) of research that require IBC review and approval before initiation. In contrast, the dedicated clinical research callout embedded within Section IV-2 significantly limits the scope of research subject to IBC oversight to a handful of products that meet a small number of triggers. As a consequence, some of the exact same products (e.g., genetically modified cells and primary cells) that require IBC review in a laboratory setting would be excluded from IBC oversight in the clinical research setting on the basis that they do not meet the narrow list of criteria for oversight (i.e., they are not capable of shedding, replicating, or integrating, and do not require "higher-risk" manipulations). We do not believe this distinction in oversight requirements between laboratory and clinical research is defensible from a biosafety perspective. Moving a product from a laboratory to a clinic does not reduce the intrinsic risks of the product. If anything, handling of genetically modified products intended for administration into human research participants can introduce exposure pathways that may not exist in a contained laboratory environment, which arguably warrants equal or greater biosafety scrutiny, not less.

To illustrate the gap concretely, we describe a life cycle of an investigational product as it moves from the laboratory to the clinic. For this representative example, the product consists of chimeric antigen

receptor T (CAR-T) cells intended for intravenous administration in a clinical trial. While the product is designed, modified, formulated, and tested in the laboratory, its genetically modified characteristics would classify this as research that requires IBC review. When the identical product is shipped to a clinical site for a clinical trial, the research would now be excluded from IBC review since the CAR-T formulation meets none of the triggers (shedding, replicating, or integrating) and does not require a higher risk manipulation such as aerosolization or bladder infusion. This ignores the fact that the material and the risks to the people handling it in the clinic is the same as in the laboratory. Arguably, the steps that carry exposure potential in the clinical setting are new: receipt and storage, thawing, withdrawal of doses into syringes or infusion bags, transport through the facility from the place of preparation to the infusion area, syringe or infusion line priming, administration, and disposal of vials, syringes, infusion bags and tubing. The realistic exposure events in this scenario include needlestick injuries, splashes to the eyes or mucous membranes, aerosols generated during preparation, and spills, among others.

Since staff can be exposed to investigational products, like CAR-Ts during the entire life cycle of a clinical trial, this warrants comprehensive biosafety oversight that is not fully appreciated in the limited clinical research callout. Applying a more permissive standard to clinical research with these same products, without a clear safety-based rationale, is an inconsistency that diminishes the real risks these products present and sits uneasily alongside the draft Policy's own stated purpose of ensuring that "gold-standard science is conducted under gold-standard biosafety conditions."

We recognize that NIH may intend to make clear that once a product is administered, the research participant does not need to be contained at the same level as the product itself. We agree. A participant is not a biohazard to be contained. Our concern is different. As drafted, the callout ties oversight to the type of research (clinical versus laboratory) and not to the risk of the product and the handling steps around it. We do not believe NIH intended this loophole.

It must also be stressed that these biosafety risks in the clinical space are not adequately being addressed by other oversight bodies. Institutional Review Board (IRB) review focuses on risks to research participants and the adequacy of informed consent, and IRBs commonly rely on IBC review for biosafety assessments. The Food and Drug Administration (FDA) reviews safety, efficacy, and manufacturing quality for trial participants, but does not set biosafety precautions for clinical sites. The literature reports no consensus guidelines for healthcare workers (HCWs) handling gene therapy products (Applied Biosafety 2020, doi:10.1177/1535676020934917), and a pharmacy review notes a lack of clinical guidance from NIH, FDA, the Centers for Disease Control and Prevention (CDC), and the World Health Organization on the clinical application of gene therapy (Gene Replacement Therapy: A Primer for the Health-system Pharmacist, PMC7675776). Without IBC review, no oversight body is formally assigned to assess these handling risks further stressing the importance of maintaining comprehensive biosafety oversight of clinical research by the IBC.

A product cannot simultaneously be deemed hazardous enough in the laboratory to warrant IBC oversight, but deemed safe enough in the clinic to warrant waiving the need for IBC oversight. Such an incongruency is antithetical to responsible biosafety governance.

4. The limited scope of products subject to IBC review per the brief clinical research callout appears to exclude an entire class of products with significant biosafety implications: gene editing platforms. While some gene editing platforms are integrating, many are not. Base editors and prime editors rewrite individual bases without inserting a gene copy or other exogenous genetic material. Additionally, nucleases (e.g., CRISPR) that create double-strand DNA breaks can, when repaired by non-homologous end joining (NHEJ), disrupt a gene(s) without any integration event. These non-integrating gene editing products meet none of the clinical research callout criteria (bullets a d) and would be excluded from IBC oversight. The callout triggers might capture some viral vector-mediated gene editing products, however, they would all the miss lipid nanoparticle (LNP)-based and other non-viral editing products that are in active clinical development. We believe this is a significant gap in oversight that should be addressed.

We recognize that most editing products in clinical research today are edited ex vivo which concentrates the hazard in the laboratory and manufacturing facilities. Exposure potential to the gene editing components is lower once the final cell product reaches the clinic thus supporting less clinical research oversight using the risk-tiering model. However, the clinical field is increasingly moving toward the use of in vivo gene editing therapeutic approaches (doi.org/10.1016/j.gendis.2025.101808), in which staff are expected to handle the gene editing reagents directly. This creates a high-consequence accidental exposure risk that unquestionably requires IBC oversight. By accidental exposure we mean unintended contact between a person who is not the intended research recipient and the active editing components, such as a needlestick during preparation or administration, a splash to the eyes or mucous membranes, inhalation of aerosols during preparation or transfer, a spill during storage, thawing, or transport; and, for vehicles that are shed, contact with patient fluids or waste. The consequence of exposure depends on the delivery system, formulation, dose, and route, but ultimately, the risk is clear with potential outcomes involving irreversible changes to the genome which cannot be treated.

The risk is even more consequential when you consider the potential for germline transmission if gene editing components reach reproductive tissues. FDA asks sponsors to assess biodistribution, including to gonadal tissue, in the product's investigational application, but its genome editing guidance is directed to sponsors and to editing of somatic cells. It does not address how site staff should safely handle or secure the product exposing the gap in oversight if IBCs aren't reviewing this research. NIH has also historically declined to support grant proposals for germline alteration. By excluding IBC review of most clinical research involving gene editing, an obvious consequence is the elimination of the local IBC checkpoint that confirms that a specific protocol and its handling procedures do not create a pathway to unintended germline editing.

Lastly, gene editing reagents and delivery vehicles are dual-use technologies that can be misused requiring comprehensive governance. The draft Policy asks IBCs to determine appropriate biosafety and biosecurity measures for research (Section III-B). Excluding clinical gene editing products removes that review for the products most likely to be handled outside traditional laboratories, and it weakens the consistent institutional governance that rigorous ethical and safety standards for gene editing depend on.

We therefore recommend that NIH revise the Policy to include "gene editing" or "genetic modification" as an independent trigger for IBC review of clinical research, alongside shedding, replicating, and

integrating. This would ensure that no current or future gene editing approach falls outside IBC oversight of clinical research.

5. The limited scope of products subject to IBC review of clinical research reasonably excludes classes of recombinant and synthetic nucleic acid molecules, such as messenger RNA (mRNA) and plasmid DNA products, from IBC review. We recognize that many of these products present a comparatively low biosafety risk profile and agree that oversight should be calibrated to risk. However, the categorical exclusion of these products from IBC oversight based solely on the absence of "shedding, replicating, or integrating" properties or "higher-risk manipulation" creates a legitimate gap in safety oversight. In clinical research, mRNA- and plasmid-based products can be engineered to express biologically potent transgenes, including gene editing components, toxins, cytokines, immune modulators, constitutively active signaling molecules, engineered receptors, and other products capable of producing clinically significant biological effects and consequences from occupational exposure. The occupational exposure risks of these products are not negated simply due to the absence of "shedding, replicating, or integrating" capability. We recommend that NIH reconsider the blanket exclusion of these products from IBC oversight of clinical research. At a minimum, we recommend that NIH preserve some mechanism (e.g., delegated review) by which nucleic acid-based clinical products can be evaluated for biosafety risk (nature of the transgene involved, mechanism of action, or other biological function) rather than being categorically excluded from oversight based solely on product class.

6. We recommend that NIH clarify whether delegated review under draft Policy Section IV-3 is available for clinical research. Section IV-2 of the draft Policy has a specific callout for clinical research. By contrast, Section IV-3, which permits review by an individual or subgroup of IBC members, has no comparable callout. It is unclear whether this omission was intentional. We ask NIH to state clearly, in the final Policy or other published guidance, whether delegated review can be applied to clinical research. If it can, we encourage NIH also to clearly state which section controls when a product qualifies under both. For example, clinical research with a genetically modified Risk Group 1 (RG1) agent could presumably qualify for delegated review under Section IV-3. If that agent can replicate or shed, it could also simultaneously meet a clinical research criterion in Section IV-2 and require full IBC review. The Policy should explicitly state whether the full IBC review requirement takes precedence in cases such as this.

7. We recommend that NIH define "shedding" as used in draft Policy Section IV. The term is applied inconsistently across the biosafety and clinical research communities. Depending on the assay and detection method, "shedding" can mean detection of an infectious, transduction-competent organism (e.g., a replication-competent viral vector) or detection of non-infectious DNA fragments in patient secretions or excretions. FDA's shedding guidance defines shedding as the release of a virus- or bacteria-based gene therapy or oncolytic product from the patient through excreta, secreta, or the skin. We encourage NIH to build on that definition and to specify whether detection of non-infectious nucleic acid fragments qualifies. This distinction matters because DNA fragments alone do not necessarily indicate the presence of a viable, transmissible biohazard. An undefined term such as this could sweep low-risk products into IBC review, or exclude genuinely higher-risk ones, based on assay design rather than actual biosafety risk. Undefined shedding criteria may also result in inconsistent institutional decision-making. For example, one institution may conclude that transient detection of vector sequences by polymerase chain reaction (PCR) constitutes shedding and therefore requires IBC review of a protocol, while another

institution may require evidence of viable, infectious, or otherwise biologically active material before applying the same trigger. As a result, identical protocols could receive materially different oversight determinations depending on local interpretation. Because “shedding” is one of the clinical research criteria that determines whether a given investigational product remains within the scope of IBC review, we encourage NIH to define this term unambiguously in the final Policy, rather than leaving it open to differing institutional interpretations.

8. We recommend that NIH define “replicating” as used in draft Policy Section IV. The Policy does not specify the threshold at which a product is considered capable of “replicating.” This can create uncertainty and inconsistency in intra- and inter-institutional application of oversight. Institutions could reach different oversight determinations for products that are replication-competent, conditionally replicating, selectively replicating, helper-dependent, or single-cycle systems. What about replication-defective vectors that may be defective for replication in individuals with intact immune systems, but could be competent in immunocompromised or immunosuppressed individuals? Furthermore, to add to the ambiguity, it is unclear whether the reference to “replicating” is intended to extend beyond infectious systems to other non-infectious products such as self-amplifying RNA (saRNA), replicons, and similar technologies that replicate DNA/RNA transiently before degrading. We recommend that NIH define this term unambiguously in the final Policy to minimize variability in application. Without clearer definitions or examples, one institution may determine that IBC review is required while another exempts the same study, resulting in inconsistent oversight outcomes for equivalent biosafety risks.

We further recommend that, if NIH intended to exclude non-infectious recombinant nucleic acid products (such as saRNA and replicons) from IBC oversight, NIH reconsider and preserve a mechanism (whether through IBC review or delegated review) by which replicating nucleic acid-based clinical products can be evaluated for biosafety risk based on the unique nature of the platform and transgenes involved, rather than excluding them from any oversight based on product class alone. The literature shows that self-amplifying mRNAs have yielded replication-competent virus through a mechanism of aberrant homologous RNA recombination (doi:10.1128/mbio.02494-24). Furthermore, saRNA can drive prolonged expression and innate immune activation (PMC12469313) compared with conventional mRNA, so the consequence of an occupational exposure scales with the transgene it encodes. For these reasons, we believe saRNA and replicon systems warrant some degree of IBC review and advocate against their categorical exclusion from IBC oversight. At a minimum, we recommend that NIH preserve some mechanism (e.g., delegated review) by which these clinical products can be evaluated for biosafety risk (e.g., replication potential, nature of the transgene involved, mechanism of action) rather than being categorically excluded from oversight based solely on product class.

9. We recommend that NIH define “higher-risk manipulation” as used in draft Policy Section IV-2. The term is illustrated by example only (e.g., aerosolization, bladder infusion) and is, otherwise, left open to interpretation. The subjective nature of this term creates an effectively unenforceable standard for IBCs. “Higher-risk” is not a term with an agreed-upon standardized meaning within the biosafety community, and, absent a formal definition, different IBCs (or the same IBC evaluating different protocols over time) could reach different conclusions about whether a given manipulation procedure qualifies for IBC review. Without an objective definition or a more complete illustrative list, institutions and IBCs are likely to apply this trigger inconsistently, undermining the draft Policy’s stated goal of a predictable oversight

framework.

Additionally, the two representative examples provided for “higher-risk manipulation” refer to administration procedures only and do not address higher-risk manipulations that may occur during preparation of the product (e.g., syringe-to-syringe transfers that can create high-pressure sprays of product if the connections are not secure). Preparation of investigational products is arguably as risky as administration, if not more so, and should be equivalently considered in a definition of “higher-risk manipulation.” Given the choice of examples of higher-risk manipulation, it is unclear whether the NIH intends to apply this criteria to all clinical research procedures, or only to administration procedures. We recommend NIH clearly define their intent and include any procedure (preparation or administration) within its scope. For consideration, NIH could define the term as follows: “A higher-risk manipulation is a procedure that, based on comprehensive risk assessment of the preparation and administration procedures, creates a greater potential for exposure of personnel or contacts than can be managed through standard precautions alone. The term may include, but is not limited to, procedures that (a) generate aerosols or droplets of the product (e.g., inhalation, nebulization, or intranasal delivery), (b) place the product on a mucosal surface or in a body cavity or lumen from which release to other persons is plausible, such as intravesical instillation, or (c) can otherwise reasonably be anticipated to create splashes, sprays or spills of the biohazard that may warrant additional engineering or work practice controls.”

NIH may identify additional manipulations in accompanying guidance and should explicitly empower IBCs to designate any particular manipulation procedure as “higher-risk” based on risk assessment.

10. The draft Policy is ambiguous about whether cellular therapies manufactured ex vivo are subject to the clinical research callout. We recommend that NIH expressly clarify whether cell therapies manufactured ex vivo with integrating vectors and/or gene editing platforms fall within the scope of IBC review of clinical research. For example, CAR-T cells manufactured with lentiviral vectors or hematopoietic stem cells (HSCs) edited with clustered regularly interspaced short palindromic repeats (CRISPR) would not directly trigger any of the main criteria (“shedding, replicating, or integrating”) required for IBC oversight. This is a significant, unaddressed question that covers a widely used class of clinically relevant investigational products that are currently considered within the scope of the NIH Guidelines. Institutions attempting to resolve this ambiguity independently are likely to do so inconsistently.

Handling precautions for these products rest on two layers which address the risk of infectious disease from human-derived materials, including standard precautions and the Occupational Safety and Health Administration (OSHA) Bloodborne Pathogens Standard. Neither of these address any novel risks created by genetic modification itself, the presence of residual replication-competent vector or gene editing components, or the hazardous nature of the transgene. FDA-approved labeling for CAR-T products also recognizes both layers. For example, the package insert for YESCARTA® (tisagenlecleucel) directs sites to employ universal precautions and also to follow local biosafety guidelines applicable for handling and disposal of the cells which have been genetically modified with a retrovirus. The IBC is the body that establishes those local guidelines. If ex vivo manufactured cell products fall outside the Policy, that labeling reference points to a governing body that no longer has an authorized role in establishing

handling guidelines for these products. We do not suggest that these products require high containment, but do ask for oversight that is proportionate to the risk. We recommend that NIH keep genetically modified cellular products within scope and make delegated review under Section IV-3 available, so that the IBC can confirm product characterization (such as vector type and replication-competent virus testing) and site handling procedures without a full committee review.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: 1. We support retaining Risk Groups (RGs) as the baseline for risk assessment. A Biosafety Level (BSL) is the containment used to work safely with an agent or product. It is a control measure, and its assignment is derived from the characteristics of the agent or product and the nature of the work proposed. The RG is a primary determinant of those characteristics, because it classifies an agent by severity of illness, route of exposure, infectious dose, rate of transmission, and availability of countermeasures. Section V-E of the draft Policy makes the same point: RGs describe the biological properties of the agent, and the appropriate BSL may be lower or higher depending on the work proposed. Section V-B likewise states that risk assessment for a genetically modified agent starts from the risks of the parent agent, which are then adjusted for the modification. Using the BSL as the baseline would start from the control measure rather than the hazard it is meant to address. The RG of the wild type organism should therefore remain the basis of risk assessment, with the BSL assigned as an outcome of that assessment.

2. We recommend that NIH state clearly whether BSL assignment by the IBC is required for clinical research conducted in clinical (non-laboratory) settings. The draft Policy acknowledges, in Section V-E, that clinical research "is most often conducted in clinical settings that do not conform to laboratory BSLs," yet stops short of stating definitively whether IBCs are required to, or not, assign a BSL to clinical research. The draft meeting minutes template and incident report template compound this ambiguity, as they both require the approved BSL containment level to be recorded. This gap is a recurring source of confusion in application due to the differences in terminology used in laboratories versus clinical environments which do not traditionally use BSLs in practice.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): We support the draft Policy's encouragement of voluntary compliance by entities not otherwise subject to it, such as non-NIH-funded institutions. Biosafety oversight protects staff, the surrounding community, and the environment from risks that do not depend on the source of an institution's funding. It helps institutions without federal funding adopt recognized best practices for risk assessment, containment, training, and incident response. It also promotes consistency, because research conducted to a common standard is easier to compare, oversee and trust. Products that move between funded and unfunded settings are also then handled under comparable safeguards. Voluntary adoption can also build a culture of biosafety that carries forward if an institution later receives NIH funding. We encourage NIH to support voluntary adopters by making the Policy's templates, definitions, and implementation resources publicly available and easy to use.

We encourage NIH to go further for institutions that are not subject to the Policy by adding educational and outreach resources, such as webinars, frequently asked questions, and short training modules written for institutions without an existing biosafety program to illustrate the value of biosafety governance. Other options include guidance on how an institution without an IBC can obtain oversight

through shared or collaborative arrangements, and a simple voluntary way to signal adoption, such as public recognition of institutions that follow the Policy. Making voluntary participation easy and visible would extend consistent biosafety governance to research outside NIH funding.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1. We support NIH's intent to promote transparency and public accountability through the public posting of incident reports. That said, we respectfully raise a concern that this requirement, as currently structured, may have an unintended consequence that runs counter to its own goal of consistent and faithful incident reporting. Individuals who are aware that an incident involving them personally will be posted to a public-facing website may become less willing to report that incident (whether out of concern for their own privacy, professional reputation, or standing with their employer), which in turn could delay or discourage them from seeking appropriate medical attention or triggering a timely institutional response. We encourage NIH to consider additional reporting safeguards that would preserve transparency while minimizing any resistance to frontline reporting. Specific safeguards, and a proposed standard for what should and should not appear in publicly posted reports, follow below.

2. We recommend that NIH clearly specify, in the final Policy or in the templates, what information should not appear in publicly posted incident reports and what information should. We offer the following starting point for consideration. Information that should not be posted includes: (a) names or other identifying details (e.g., position titles) of principal investigators and staff, including any other detail that would reasonably allow a person to be identified at a small site through title, role, dates, or a combination of descriptors; (b) personal health information, including diagnoses, treatment, test results, and follow-up for any individual; (c) location detail that could create a security or safety risk, such as building name or room number; and (d) sponsor-confidential or proprietary information, such as investigational product descriptions. Information that is useful to the public and supports learning from incidents includes the type of incident and the agent category and Risk Group; the setting (BSL) and the activity being performed during the incident; whether an overt exposure occurred, by what route, and what response followed; and the root cause and the corrective and preventive actions taken.

The following two scenarios illustrate situations that show why careful consideration of what information is included in an incident report matters. Scenario 1: A needlestick occurs while one pharmacist prepares a study dose in a small hospital pharmacy. A posted report that identifies the role ("pharmacist") and the date easily identifies the employee if there's just one pharmacist working on that day. Scenario 2: A splash to the eye occurs while a graduate student is manipulating an agent in a laboratory. The laboratory is small and has just one graduate student and a technician. A posted report that identifies the role ("graduate student") and the date would likewise identify the employee. As noted previously, staff who anticipate potential for their identification may delay or avoid reporting.

3. We recommend for consideration the following five safeguards, which would preserve transparency while protecting reporters, participants, and security: (i) a two-tier format, in which the full report goes to the IBC and NIH and the public version is a standardized, de-identified summary generated from the same template, with each template field designated as public or restricted; (ii) a single national redaction standard based on the lists above, applied uniformly, with worked examples of acceptable and unacceptable postings published by NIH; (iii) summary-level or aggregate posting where small numbers could identify a person, for example at sites with few staff; (iv) a confidential reporting pathway for

individuals to the IBC or biological safety officer, together with a statement that the public version will be de-identified and that reporting is protected from retaliation; and (v) review of the public version by the IBC or its administrator before posting. NIH could also use its planned Annual Incident Summary Report (Section III-D) and the voluntary confidential near-miss reporting channel to the National Biosafety Data and Safety Analysis Center (Section III-C) to share lessons learned without institution-level detail.

6. Other feedback relevant to this resource: 1. It is not clear whether the Biosafety Assurance requirement, including the biosafety policies and procedures that support it, can be fulfilled by an externally administered IBC on behalf of the institutions it serves. We recommend that NIH state explicitly, in the final Policy or in subsequent guidance, that it can. We believe this is sound for the following reasons. The Biosafety Assurance requirement, as drafted, may create challenges for institutions that exclusively rely on externally administered IBCs to support their biosafety oversight obligations. Community hospitals and clinics, private practices, rural research sites, and other smaller institutions frequently depend on externally administered IBCs because they lack the expertise or resources to maintain a fully constituted internal IBC and biosafety program. Many of these institutions are unlikely to have independently developed the biosafety policies, procedures, and supporting documentation that the Assurance appears to mandate. Requiring each such institution to develop this documentation independently, from scratch, would impose a significant, and in many cases disproportionate, compliance burden without materially improving biosafety outcomes. Allowing their externally administered IBC provider to furnish these documents for them removes this barrier. Furnishing documents does not, by itself, ensure that an institution follows them. We therefore suggest that NIH require, as a condition of approving a Biosafety Assurance that relies on externally furnished documents, a documented attestation that the institution will follow the policies and procedures supplied by its externally administered IBC. However, we also do recognize NIH's parallel effort to reduce regulatory burden. To avoid another institutional attestation, NIH could instead make this commitment a term and condition of funding awards. Either way, the Assurance would reflect both the existence of appropriate biosafety documentation and the institution's commitment to follow it.

2. The requirement to host and continually update public postings (the IBC roster, meeting minutes, and incident reports) applies to every institution, but the burden of meeting that requirement varies widely with an institution’s available resources. Universities and large academic medical centers often have the web infrastructure, IT staff, and financial resources to meet this requirement. Smaller institutions, including rural practices, community clinics, and individual sites within larger networks may have few or none of these resources, so the same compliance requirement can impose a disproportionate burden. We see two ways to address this and support either. Option 1 lets institutions that contract with an externally administered IBC have that IBC meet the posting requirements on their behalf. Option 2 has NIH establish and host a single, centralized system for submitting and publicly posting IBC records.

Option 1. We recommend that NIH explicitly permit externally administered IBCs to host required public-facing postings (the IBC roster, meeting minutes, and incident reports) on behalf of the institutions they serve, rather than requiring each institution to build and independently maintain this capability. This flexibility would be particularly important for institutions that are not well positioned to build and maintain the IT infrastructure themselves (e.g., rural practices and small community clinics). Based on our experience administering IBCs for a diverse range of institution types, we see recurring financial, technical, operational, logistical, and legal barriers for some institutions to maintain a continually

updated public-facing website:

a. From a cost standpoint, rural and community practices, small physician offices, and similar non-academic institutions often use a website that was built as a one-time, basic marketing expense and lack the operating budget to update it promptly and repeatedly after each IBC meeting or reportable incident.

b. Technically, many of these institutions often have no in-house web development or IT staff or standing vendor relationship, and their websites were not designed to support recurring, structured regulatory postings. Third-party vendors commonly handle updates through formal change-request processes, which can delay postings beyond the Policy's timelines (e.g., posting minutes promptly after approval, or incident reports within 30 days). The five-year minimum posting requirement makes this an ongoing content management and retention burden, which compounds over time for institutions without a scalable web management process.

c. Logistically, institutions that are part of larger, multi-site or multinational networks may have no authority, access, or technical means to modify the entire corporate public-facing website governing the network as a whole. A single site conducting research subject to the Policy may depend on a centralized corporate or franchise structure that was not built to accommodate this specific compliance need.

d. From a legal standpoint, multinational site networks may host their website on a platform or domain governed by non-U.S. data privacy or content regulations (e.g., the General Data Protection Regulation, or GDPR), which may require an additional level of legal review before certain clinical trial content can be posted which can affect compliance with the Policy's timelines. Separately, in clinical research, it is often the trial sponsor that holds the direct funding relationship with the NIH and not the individual trial sites (institutions). Non-funded sites may legally challenge their obligation to update their websites to satisfy the sponsor's compliance obligations which can pose a significant barrier to IBC compliance with the public-facing postings

Centralizing postings with a qualified external IBC administrator which has the subject-matter expertise, infrastructure, and operational capacity to manage them consistently and in compliance with the Policy's redaction, posting, and timing requirements, would materially reduce these burdens while preserving the transparency the Policy is intended to achieve. We would further note that this approach is not merely a burden-reduction measure for institutions; it would likely advance NIH's own transparency and compliance objectives more effectively than the current site-by-site model. A single, centralized location maintained by a qualified external IBC administrator would be more consistently accurate, complete, and up to date than dozens or hundreds of independently maintained institutional websites that differ in format and resources, and would allow the public, researchers, and NIH itself to locate and review IBC rosters, meeting minutes, and incident reports for all covered institutions in one place, rather than needing to identify and navigate each institution's individual website. We believe centralization of records with the externally administered IBC would result in materially greater public transparency and easier public access to these records than the current, fully decentralized posting model contemplated by the draft Policy, while also making compliance considerably easier for NIH to monitor.

Option 2. As an alternative, or as a complement, NIH could establish and host a centralized system for the submission and public posting of IBC rosters, meeting minutes, and incident reports. This would create a nationally universal repository of IBC records for all institutions, whether their IBC is internal or externally administered. Institutions would submit records once, using the NIH templates, and the system would apply the redaction standard consistently and post the public version. Benefits include a single searchable location for the public, researchers and NIH; uniform formatting and redaction; no need for each institution to build or maintain a website; easier NIH monitoring of compliance and trends, including through the Annual Incident Summary Report; and lower cost and burden across the research enterprise. NIH would retain policy control and could set requirements for data security, privacy protection, institutional review before posting and independent oversight of the operator.

3. We recommend that NIH provide guidance on how intermediate-size and large-size population expanded access protocols are intended to be treated under the Policy. The draft Policy addresses individual-patient expanded access use under an FDA-regulated IND application as being outside the scope of IBC review, but does not address other forms of expanded access protocols that are also common (e.g., intermediate- and large-population protocols). We request that NIH clarify how these other forms of expanded access are intended to be treated differently, if at all, relative to individual-patient use to avoid confusion and inconsistent oversight from institution to institution.

4. If NIH intends to narrow the clinical research scope, we recommend that NIH issue clear guidance on how IBCs should manage the transition of oversight for clinical studies that are currently within the scope of IBC review under the current NIH Guidelines, but would fall outside the narrower scope of the Policy once it takes effect. The guidance should address at minimum (i) whether and how active protocols may transition out of IBC oversight; (ii) how continuity of biosafety oversight is handled for participants already enrolled; and (iii) how the transition is managed and documented. We encourage NIH to provide this direction rather than leave it to individual institutions and IBCs to resolve independently, which risks inconsistent implementation and avoidable gaps in oversight during the transition.

5. We recommend that NIH replace the award-linked retention period for IBC minutes and incident reports with a fixed maximum period. Draft NIH Policy Section III-A ties IBC records to Section 8.4.2 of the NIH Grants Policy Statement, which requires retention for three years after an award's final financial report, and minutes and incident reports must also be posted for at least five years. For a five- or ten-year center grant, public availability could therefore far exceed five years. At most institutions, IBCs generally do not know every award that supports a given protocol or when each award closes, and their document management systems are typically not designed to track this. To further compound the complexity, with this new requirement, the system would need to be able to crosslink protocols that may simultaneously be tied to several principal investigators and several grants, or grants that transfer with an investigator departing to another institution. Linking IBC records to grants would require significant financial investment and operational effort and, depending on system design, a complete IT system rebuild.

The Policy would also need to address how non-funded institutions are to navigate the award-linked retention period when the institution has no visibility to the grant funding timelines. This would be

particularly relevant for clinical research sponsored by funded entities ("Sponsors") and conducted at non-funded trial sites. Similarly, externally administered IBCs are independent of the institutions they serve and do not hold or have access to their grant records. It cannot see when an institution's awards are renewed, extended, transferred or closed, so it has no means to link its records to NIH award timelines. Only the institutions themselves hold that information creating a significant barrier to this drafted compliance requirement.

Given these likely hurdles to compliance, we recommend a fixed period measured from the date of posting, such as five years, which matches the minimum already in the draft Policy. Institutions would remain responsible for retaining records under the Grants Policy Statement. If NIH keeps an award-linked approach, we ask that NIH provide a sufficiently long implementation period to allow for all manner of institutions to rebuild their systems to facilitate compliance with this new mandate.

National Institutes of Health
Office of Science Policy

Re: NOT-OD-26-112 Draft NIH Biosafety Policy for Research Involving Biohazards

October 19, 2026

Dear NIH Office of Science Policy,

Sabai appreciates the opportunity to provide input on the National Institutes of Health's (NIH) draft policy on Biosafety for Research Involving Biohazards. Sabai operates in the clinical research space specializes in providing biosafety and human research protections through provision of independent Institutional Biosafety Committee (IBC) and Institutional Review Board (IRB) services. We acknowledge the efforts of the NIH to modernize biosafety practices across biomedical research efforts, given the ever-shifting landscape of modern science. We also appreciate the goal of NIH to strengthen the role of IBCs in biosafety regulation. This letter accompanies our comment form responses and summarizes our principal recommendations.

Scope of Clinical Research Oversight:

As currently written, Section IV of the policy can be interpreted in two vastly different ways. First, that clinical research **only** requires review and oversight if it satisfies the specific callouts found in Section IV-2. Second, that Section IV applies to all research, spanning from basic to clinical, and that **in addition**, clinical research has a specific set of risks outlined in Section IV-2 beyond those captured by other sections. Institutions, clinical trial sponsors, and IBCs may have difficulty resolving NIH's intention from the published text alone. **Sabai recommends that NIH revise this section to clearly establish that clinical research is subject to the same level of oversight as laboratory research, with additional conditions as outlined in Section IV-2.**

If NIH does intend to reduce the scope of clinical research subject to IBC oversight, **we believe this will lead to an insufficient level of oversight**. Carving out clinical research from oversight requirements and narrowing the scope to only reviewing products capable of shedding, replicating, or integrating, or the requirement of "higher risk" manipulations creates an oversight gap and double standard between clinical research and laboratory research. Some examples of resulting biosafety risk include:

- Certain products that require IBC review in a laboratory setting (e.g., genetically modified cells, primary cell lines) would be excluded from IBC oversight. Moving a product from a laboratory to a clinic does not reduce the intrinsic risks of the product. Administering a genetically modified product to a human research participant may introduce novel exposure pathways that do not exist in a contained laboratory environment, which arguably warrants equal or greater biosafety scrutiny, not less. Applying a more permissive standard to clinical research with these same products, without a clear safety-based rationale is an inconsistency that diminishes the real risks these products present.
- The limited scope of products subject to IBC review per the brief clinical research callout appears to exclude an entire class of products with significant biosafety implications: gene editing platforms. Given the increasing prevalence of in vivo gene editing therapeutic approaches and the corresponding risks of exposure events leading to irreversible genomic alterations, we believe the absence of oversight for this product class is not commensurate with the risks these products pose. Furthermore, given the potential for germline transmission and alteration, and dual-use misuse of the technology, gene editing requires rigorous ethical and safety standards and biosafety governance, not less as the draft Policy would support.

- The limited scope of products subject to IBC review of clinical research would exclude classes of recombinant and synthetic nucleic acid molecules, such as mRNA and plasmid DNA products, from IBC review. We recognize that many of these products present a comparatively low biosafety risk profile and agree that oversight should be appropriately calibrated to risk. However, their categorical exclusion based solely on the absence of "shedding, replication, or integration" properties or "high-risk manipulation" creates a legitimate gap in safety oversight. The occupational exposure risks of these products are not negated simply due to the absence of "shedding, replication or integration" capability. If NIH plans to exclude this research from oversight, the policy should preserve some mechanism (whether through IBC review, delegated review, or another appropriate pathway) by which nucleic acid-based clinical products can be evaluated for biosafety risk rather than being excluded from oversight completely.
- Cellular therapies manufactured ex vivo with integrating vectors and/or gene editing platforms may fall outside the scope of clinical research oversight. For example, chimeric antigen receptor T (CAR-T) cells manufactured with lentiviral vectors or CRISPR-edited hematopoietic stem cells (HSCs) would not directly trigger any of the main criteria ("shedding, replicating, or integrating") required for IBC oversight. This exclusion would cover a widely used class of common, clinically-relevant investigational products that currently are considered in scope of the NIH Guidelines. In the absence of IBC oversight, no other governing body is currently positioned to evaluate the risks created by genetic modification.

If NIH does intend to narrow the clinical research scope, we recommend that **NIH issue clear, consistent guidance addressing how local and externally administered IBCs should manage the transition of oversight for clinical studies that are currently within the scope of IBC review under the current NIH Guidelines, but that would no longer meet the narrower clinical research scope described in Section IV-2 once the final Policy takes effect.** We recommend that this guidance address, at minimum: (i) whether and how currently active protocols may transition out of IBC oversight, (ii) how continuity of biosafety oversight should be handled for research participants already enrolled at the time of transition; and (iii) how the transition period itself should be managed and documented. Clear transition expectations would promote continuity of biosafety oversight, preservation of institutional knowledge, uninterrupted access to study records, and consistent management of participant safety issues that may emerge after enrollment.

Use of External IBCs:

We recommend that NIH explicitly permits externally administered IBCs to furnish the biosafety policies and procedures required to support an institution's Biosafety Assurance on behalf of the institutions they serve. Community hospitals and clinics, physician practices, rural research sites, and other smaller institutions frequently depend on external IBCs because they lack the expertise and/or resources necessary to maintain a fully constituted internal IBC and associated biosafety program. We believe requiring institutions to write their own policies and procedures from scratch would create unnecessary barriers without materially improving biosafety outcomes. Allowing the externally administered IBC provider to furnish the biosafety policies, procedures, and other supporting documentation on behalf of the institutions it serves would avoid this heavy burden and eliminate the compliance gap.

We recognize, however, that furnishing these documents alone does not ensure that the institution will actually adhere to them in practice. We therefore suggest that NIH require, as a condition of an Assurance that relies on externally furnished documentation, a documented attestation from the institution acknowledging that it will follow the biosafety policies and procedures supplied by its externally administered IBC. Alternatively, we would also support an attestation of this nature to be incorporated into the terms and conditions of awards, reducing regulatory burden while maintaining biosafety gold-standard practices.

Further, we recommend that **NIH explicitly permit externally administered IBCs to host required public-facing postings (the IBC roster, meeting minutes, and incident reports) on behalf of the institutions they serve, rather than requiring each institution to build and independently maintain this capability.** This flexibility

would be particularly important for institutions that are not large universities or major academic medical centers and that may not be well positioned to build and maintain the IT infrastructure themselves (e.g., rural practices and small community clinics). Centralizing these postings with a qualified external IBC administrator, an entity with the subject-matter expertise, infrastructure, and operational capacity to manage them consistently and in compliance with the Policy's redaction, posting and timing requirements, would materially reduce these burdens for institutions while preserving the transparency the Policy is intended to achieve.

As an alternative or a complement, NIH could establish and host a centralized system for the submission and public posting of IBC rosters, meeting minutes, and incident reports. This would create a nationally universal repository of IBC records for all institutions, whether their IBC is internal or externally administered.

Use of Risk Groups (RGs) as a Baseline for Risk Assessment:

We support retaining RGs as the baseline for risk assessment. However, we recommend **that NIH clearly state whether biosafety containment level (BSL) assignment by the IBC is required for clinical research conducted in clinical (non-laboratory) settings.** The draft Policy acknowledges, in Section V-E, that clinical research "is most often conducted in clinical settings that do not conform to laboratory BSLs," yet stops short of stating definitively that IBCs are not required to assign a BSL to clinical research. The draft meeting minutes template and incident report template compound this ambiguity, as they both require the approved BSL containment level to be recorded. This gap is a recurring source of confusion in application due to the differences in terminology used in laboratories versus clinical environments.

Definitions:

We recommend that NIH more clearly define "shedding," "replicating," and "higher-risk manipulation," as used in Section IV-2. Without objective definitions, institutions and IBCs are likely to interpret these terms inconsistently, undermining the draft Policy's stated goal of a predictable oversight framework.

- **Shedding:** This term is applied inconsistently across the biosafety and clinical research communities. Depending on the assay and detection method used, "shedding" can refer either to detection of an infectious, transduction-competent organism (e.g., a replication-competent viral vector) or to detection of non-infectious DNA fragments in patient secretions or excretions. This distinction matters since the presence of DNA fragments alone does not necessarily indicate the presence of a viable, transmissible biohazard. An undefined term such as this could sweep low-risk products into IBC review, or exclude higher-risk ones, based on assay design rather than actual biosafety risk. Undefined shedding criteria may also result in inconsistent institutional decision-making. As a result, identical protocols could receive materially different oversight determinations depending upon local interpretation.
- **Replicating:** As drafted, the Policy does not specify the threshold at which a product is considered capable of "replicating." This can create uncertainty and inconsistency in intra- and inter-institutional application of oversight given that different definitions of "replication" could be applied depending on whether a product is fully replication-competent, conditionally-replicating, selectively-replicating, helper-dependent, or is a single-replication cycle system. Furthermore, to add to the ambiguity, it is unclear whether the reference to "replicating" extends beyond infectious systems to other products such as self-amplifying RNA (saRNA), replicons, and similar technologies that replicate DNA/RNA transiently before degrading.
- **Higher-risk manipulation:** As drafted, the term is illustrated only by example (e.g., aerosolization, bladder infusion) and is otherwise left open to subjective interpretation. The subjective nature of this term creates an unenforceable standard for IBCs. "Higher-risk" is not a term with an agreed-upon standardized meaning within the biosafety community, and, absent a formal definition, different IBCs (or the same IBC evaluating different protocols over time) could reasonably reach different conclusions about whether a given manipulation procedure qualifies.

Incident Report Posting:

We support NIH's intent to promote transparency and public accountability through the public posting of incident reports. That said, we respectfully raise a concern that this requirement, as currently structured, may have an unintended consequence that runs counter to its own goal of consistent and faithful incident reporting. Individuals who are aware that an incident involving them personally will be posted to a public-facing website may become less willing to report that incident (whether out of concern for their own privacy, professional reputation, or standing with their employer), which in turn could delay or discourage them from seeking appropriate medical attention or triggering a timely institutional response. **We encourage NIH to consider additional reporting safeguards that would preserve transparency while minimizing any resistance to frontline reporting.** Specific safeguards, and a proposed standard for what should and should not appear in publicly posted reports, follow below.

Thank you for your consideration of our comments. For questions, please feel free to reach out to me at gcoulson@sabaiglobal.com.

440. University of Mississippi

I am responding: On behalf of an organization

Name:

Name of Organization: University of Mississippi

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: a. Clarify the policy's boundaries

We appreciate NIH's effort to describe the research covered by the policy. A definition of "biohazard" would help institutions apply that scope consistently. The draft describes biomedical research in laboratory settings and combines a human-health risk threshold with selected categories of materials. It is less clear how institutions should treat materials that principally affect animals, plants, agriculture, or the environment, particularly given the provisions calling for IBC assessment of environmental and population effects.

We ask NIH to clarify whether these risks fall within this policy, remain outside its scope, or are addressed through another federal framework. This clarification would help institutions avoid both gaps and unnecessary duplication in oversight.

b. Calibrate toxin and protein oversight to meaningful risk

We support appropriate oversight of biological toxins and disease associated proteins. As written, however, the draft appears to cover all toxins and require delegated review of non-Select Agent toxin proteins without thresholds for quantity, potency, concentration, or activity. References to "prions and other self-aggregating proteins" may also be interpreted more broadly than the disease-associated definition.

Please consider distinguishing biological toxins from other hazardous proteins, addressing inactive derivatives, subunits, and nucleic acids encoding toxins, and establishing risk-based thresholds or exemptions. Limiting the self-aggregating protein category to transmissible or experimentally propagating disease associated materials would also help focus review on meaningful biosafety risks.

c. Clarify expectations for primary cells and established cell lines

Additional guidance on “adventitious agents” would be especially helpful. The term appears in Section IV-2’s requirement for IBC approval of research with primary cells that may be contaminated, in Section V-A’s discussion of primary cells and tissues, and in the incident reporting exception for certain post-exposure treatment.

Without a definition or examples, institutions may interpret “may be contaminated” to include nearly all primary cell work, including cells from low risk sources. It is also unclear how this provision relates to Section II’s scope and Section IV-3’s delegated review of well characterized cell lines. We would welcome a definition and examples that distinguish materials requiring full committee review, delegated review, or no review, and explain how to apply the reporting exception consistently.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): a. Explain how overlapping review categories apply

We welcome the use of tiered review to align oversight with risk. Sections IV-2 and IV-3 would benefit from a clear rule for activities that appear to fit both categories. Genetically modified cells, viruses, and organisms appear in the full committee category, while subsets of that work appear in the delegated category.

Please consider stating expressly that the most specific category controls and providing a decision table with examples of full committee review, delegated review, registration, exemption, and NIH review. This would support consistent decisions across institutions.

b. Provide streamlined pathways for routine minimal risk activities

We encourage NIH to consider exemptions or administrative registration for activities that a documented institutional screening process determines present minimal biosafety risk. Examples include commercial transgenic animals maintained at ABSL-1, low risk plasmids, replication-incompetent non-integrating vectors expressing low risk transgenes, well characterized cell lines, and genetically modified RG1 organisms.

Allowing these pathways, with institutional discretion to elevate review when local circumstances warrant, would help preserve IBC capacity for higher risk activities while retaining appropriate institutional oversight.

3. Continued utility of Risk Groups: a. Distinguish genetic engineering from other forms of change

We appreciate the intent to account for changes that may affect an organism’s risk. The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means, which could also bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory review without a demonstrated increase in biosafety risk.

We ask NIH to distinguish deliberate genetic engineering from these other processes and calibrate oversight to the resulting phenotype and risk. Examples would help institutions determine when an

activity changes the level of oversight required.

b. Support consistent risk assessment and containment decisions

We support the emphasis on risk assessment and mitigation. Institutions would benefit from practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk.

We also encourage NIH to retain a clear distinction between Risk Group (RG), which describes agent characteristics, and Biosafety Level (BSL) and Animal Biosafety Level (ABSL), which describe containment. Guidance explaining how these classifications inform, but do not substitute for, activity-specific risk assessment would be valuable.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): a. Explain how overlapping review categories apply

We welcome the use of tiered review to align oversight with risk. Sections IV-2 and IV-3 would benefit from a clear rule for activities that appear to fit both categories. Genetically modified cells, viruses, and organisms appear in the full committee category, while subsets of that work appear in the delegated category.

Please consider stating expressly that the most specific category controls and providing a decision table with examples of full committee review, delegated review, registration, exemption, and NIH review. This would support consistent decisions across institutions.

b. Provide streamlined pathways for routine minimal risk activities

We encourage NIH to consider exemptions or administrative registration for activities that a documented institutional screening process determines present minimal biosafety risk. Examples include commercial transgenic animals maintained at ABSL-1, low risk plasmids, replication-incompetent non-integrating vectors expressing low risk transgenes, well characterized cell lines, and genetically modified RG1 organisms.

Allowing these pathways, with institutional discretion to elevate review when local circumstances warrant, would help preserve IBC capacity for higher risk activities while retaining appropriate institutional oversight.

3. Risk Assessment and the Continued Utility of Risk Groups

a. Distinguish genetic engineering from other forms of change

We appreciate the intent to account for changes that may affect an organism's risk. The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means, which could also bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory review without a demonstrated increase in biosafety risk.

We ask NIH to distinguish deliberate genetic engineering from these other processes and calibrate oversight to the resulting phenotype and risk. Examples would help institutions determine when an activity changes the level of oversight required.

b. Support consistent risk assessment and containment decisions

We support the emphasis on risk assessment and mitigation. Institutions would benefit from practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk.

We also encourage NIH to retain a clear distinction between Risk Group (RG), which describes agent characteristics, and Biosafety Level (BSL) and Animal Biosafety Level (ABSL), which describe containment. Guidance explaining how these classifications inform, but do not substitute for, activity-specific risk assessment would be valuable.

4. Roles, Responsibilities, Compliance, and Transparency

a. Establish a clear foundation for IBC authority and independence

We support the requirement for an IBC and encourage NIH to pair its responsibilities with explicit institutional authority, support, and independent decision making. An “Establishing an IBC” subsection could provide a consistent foundation while allowing flexibility in institutional structure. We offer the following language for consideration:

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

b. Distinguish substantive oversight from administrative support

Clearer separation of IBC oversight functions, committee procedures, and administrative tasks would help institutions assign work appropriately and support timely responses. Please consider specifying that the IBC’s substantive responsibilities include:

Reviewing the biosafety program, including practices, training, emergency preparedness, and continued compliance.

Conducting or directing periodic, risk-based evaluations of facilities, equipment, and containment, with findings, deficiencies, and reasonable corrective plans and schedules reported to the Institutional Official or designee.

Reviewing concerns, incidents, unsafe conditions, and noncompliance; requiring corrective measures; overseeing resolution; and recommending improvements to facilities, training, and resources.

Approving, requiring modifications to secure approval, or withholding approval of covered activities and significant changes before implementation.

Suspending or withdrawing approval and requiring cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

We also encourage flexibility for qualified staff to conduct evaluations under written institutional procedures, with intervals proportionate to risk and IBC responsibility retained for oversight determinations. The IBC would approve its minutes and substantive determinations, while staff could prepare, retain, redact, and post records; communicate decisions; track deadlines; and prepare authorized submissions.

Please also clarify immediate stop-work authority and subsequent IBC review. Qualified response teams need to be able to investigate and take immediate protective action without waiting for a committee meeting.

c. Align accountability with authority

The expanded responsibilities assigned to BSOs and IBCs would be more effective if accompanied by explicit access to facilities and relevant records, direct reporting and escalation pathways, and authority to require corrective measures and stop or suspend unsafe work when necessary. We ask NIH to make these authorities clear so that institutional personnel can fulfill the responsibilities the policy assigns to them.

d. Support experienced program leadership

We appreciate the draft's recognition of the Biological Safety Officer's role. Where BSO duties are assigned to another official, equivalent qualifications and institutional support remain essential.

Please consider requiring each covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to its research portfolio. Expectations for qualifications, institutional access, reporting relationships, resources, and escalation of unresolved risks would help institutions establish effective leadership. An official performing BSO duties would need equivalent qualifications for those duties.

Guidance on the relationships among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official would also be helpful. In particular, institutions would benefit from clarification of which roles may be combined, how independence is protected, and whether the BSO's IBC role includes program administration in addition to voting membership. We encourage NIH to emphasize experience and functional authority, comparable to other institutional oversight leaders such as animal welfare directors or institutional veterinarians, while allowing flexibility in titles and administrative placement.

e. Clarify occupational health and safety expectations

We welcome the recognition of occupational health and safety as part of an effective biosafety program. The draft notes that other regulations and policies may require an Occupational Health and Safety Program. Clear triggers, assigned authorities, and responsibility for developing and communicating required procedures would help institutions understand and coordinate these obligations.

f. Clarify committee governance

Additional guidance on quorum and voting would support consistent committee decisions. We ask NIH to specify that a member recused because of a conflict does not count toward the quorum for that matter and to explain the voting denominator after recusal.

Institutions would also welcome expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

g. Map retention requirements to record types

A record retention table would be a practical aid to implementation. Please consider including protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. Identifying the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements would reduce uncertainty and inconsistent practice.

h. Provide a predictable Biosafety Assurance process

We appreciate the value of an institutional Biosafety Assurance and ask NIH to provide a standardized template and a predictable submission, approval, and renewal process. These resources would promote consistent submissions and help prevent interruptions during timely renewal.

A template could distinguish required, conditional, and optional fields and address institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. We encourage NIH to retain substantive obligations in the policy itself rather than introduce additional requirements through templates.

Please also specify required institutional signatures, the submission system, completeness criteria, and how timely renewals will be handled while NIH review is pending. Clarifying which information must be public and which may be submitted directly to NIH when public posting is inappropriate or unavailable would further support implementation.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: a. Preserve local management of lower risk events

We support reporting that enables NIH to identify significant risks and strengthen biosafety. Please consider preserving local IBC management of lower risk events and near misses, without requiring public posting of every internally reviewed minor event or unredacted identifying information. A proportionate approach would support prompt reporting and corrective action while focusing federal reporting on events that warrant that level of oversight.

b. Use aggregate reporting to advance transparency and learning

UM supports appropriate transparency regarding biosafety incidents. We ask NIH to consider whether the proposed public information, even when direct identifiers are removed, could identify individuals through contextual details and raise concerns about disclosure of protected medical information. In areas that have historically attracted harassment or threats, including animal research, public disclosure of investigator identities, funding information, or other identifying details may also create risks for researchers and animal care personnel.

We encourage NIH to meet its transparency goals through aggregated, de-identified incident data, including an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center (NBDSAC). Annual summaries of trends, contributing factors, and lessons learned could support shared learning without identifying individuals or institutions in routine, well managed incidents. Full records could remain available to NIH and other authorized reviewers for investigations of laboratory-acquired infections and other public health purposes.

For a voluntary learning system to be effective, institutions and researchers need to understand its confidentiality protections, disclosure boundaries, and relationship to enforcement. Clear parameters would help build confidence in participation and improve the usefulness of the information collected.

c. Explain how investigator duties and reporting pathways interact

Section III-C assigns investigators safe research responsibilities that intersect with institutionally managed facilities and services. We would welcome clarification of how these responsibilities are shared so investigators understand which actions they must take directly and which require institutional coordination.

Please also explain how confidential voluntary reporting to NBDSAC interacts with mandatory NIH reporting and public posting. Clear limits on confidentiality and a clear distinction between voluntary

learning submissions and required reports would help institutions participate with an accurate understanding of their obligations.

6. Other feedback relevant to this resource: a. Provide practical implementation resources

We appreciate NIH's efforts to support institutions through this transition. The following resources would be particularly valuable before implementation begins:

A Biosafety Assurance template and model institutional policies.

Decision trees, risk assessment forms, and worked examples.

Training materials for IBC members, BSOs, PIs, and staff.

Sample completed minutes and incident reports, with clear redaction guidance.

A national Risk Group and containment determination database.

Guidance for external, shared, and consortium IBC models.

Making these resources available with the final policy would help institutions develop consistent procedures and avoid repeated revisions as expectations become clearer.

b. Allow sufficient time for a coordinated transition

Implementing the proposed policy will require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research. We respectfully request at least 12 months for full implementation after final guidance and required templates are available.

Please consider staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, allowing conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher risk work, would help institutions manage the transition effectively. Preserving staggered renewal cycles would also reduce avoidable backlogs.

Description: University of Mississippi's Response to NIH NOT-OD-26-112

University of Mississippi's Response to NIH's Draft Biosafety Policy for Research Involving Biohazards

Response to NOT-OD-26-112

The University of Mississippi (UM) appreciates the opportunity to comment on NIH's Draft Biosafety Policy for Research Involving Biohazards. We support NIH's commitment to protecting human health and the environment and appreciate its efforts to engage researchers, institutions, and community members in developing a clearer, more accessible policy. Our IBC has participated in NIH's listening sessions and attended webinars hosted by BSAA, ABSA, CSHEMA, and COGR to better understand the proposed changes and their implications for our research community.

We share the goal of strengthening biosafety oversight through requirements that are clear, proportionate to risk, and practical to implement. In that spirit, we offer the following recommendations to help institutions apply the policy consistently and direct resources toward activities with the greatest potential risk.

1. Scope of Research Covered by the Policy

a. Clarify the policy's boundaries

We appreciate NIH's effort to describe the research covered by the policy. A definition of "biohazard" would help institutions apply that scope consistently. The draft describes biomedical research in laboratory settings and combines a human-health risk threshold with selected categories of materials. It is less clear how institutions should treat materials that principally affect animals, plants, agriculture, or the environment, particularly given the provisions calling for IBC assessment of environmental and population effects.

We ask NIH to clarify whether these risks fall within this policy, remain outside its scope, or are addressed through another federal framework. This clarification would help institutions avoid both gaps and unnecessary duplication in oversight.

b. Calibrate toxin and protein oversight to meaningful risk

We support appropriate oversight of biological toxins and disease-associated proteins. As written, however, the draft appears to cover all toxins and require delegated review of non-Select Agent toxin proteins without thresholds for quantity, potency, concentration, or activity. References to "prions and other self-aggregating proteins" may also be interpreted more broadly than the disease-associated definition.

Please consider distinguishing biological toxins from other hazardous proteins, addressing inactive derivatives, subunits, and nucleic acids encoding toxins, and establishing risk-based thresholds or exemptions. Limiting the self-aggregating protein category to transmissible or experimentally propagating disease-associated materials would also help focus review on meaningful biosafety risks.

c. Clarify expectations for primary cells and established cell lines

Additional guidance on "adventitious agents" would be especially helpful. The term appears in Section IV-2's requirement for IBC approval of research with primary cells that may be contaminated, in Section V-A's discussion of primary cells and tissues, and in the incident-reporting exception for certain post-exposure treatment.

Without a definition or examples, institutions may interpret "may be contaminated" to include nearly all primary cell work, including cells from low-risk sources. It is also unclear how this provision relates to Section II's scope and Section IV-3's delegated review of well-characterized cell lines. We would welcome a definition and examples that distinguish materials requiring full committee review, delegated review, or no review, and explain how to apply the reporting exception consistently.

2. Tiered Oversight and Calibration to Risk

a. Explain how overlapping review categories apply

We welcome the use of tiered review to align oversight with risk. Sections IV-2 and IV-3 would benefit from a clear rule for activities that appear to fit both categories. Genetically modified cells, viruses, and organisms appear in the full committee category, while subsets of that work appear in the delegated category.

Please consider stating expressly that the most specific category controls and providing a decision table with examples of full committee review, delegated review, registration, exemption, and NIH review. This would support consistent decisions across institutions.

b. Provide streamlined pathways for routine minimal-risk activities

We encourage NIH to consider exemptions or administrative registration for activities that a documented institutional screening process determines present minimal biosafety risk. Examples include commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms.

Allowing these pathways, with institutional discretion to elevate review when local circumstances warrant, would help preserve IBC capacity for higher-risk activities while retaining appropriate institutional oversight.

3. Risk Assessment and the Continued Utility of Risk Groups

a. Distinguish genetic engineering from other forms of change

We appreciate the intent to account for changes that may affect an organism's risk. The proposed definition of genetic modification includes passaging, reassortment, and chemical or radiological means, which could also bring conventional selection, adaptation, mutagenesis, and routine RG1 work into mandatory review without a demonstrated increase in biosafety risk.

We ask NIH to distinguish deliberate genetic engineering from these other processes and calibrate oversight to the resulting phenotype and risk. Examples would help institutions determine when an activity changes the level of oversight required.

b. Support consistent risk assessment and containment decisions

We support the emphasis on risk assessment and mitigation. Institutions would benefit from practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk.

We also encourage NIH to retain a clear distinction between Risk Group (RG), which describes agent characteristics, and Biosafety Level (BSL) and Animal Biosafety Level (ABSL), which describe containment. Guidance explaining how these classifications inform, but do not substitute for, activity-specific risk assessment would be valuable.

4. Roles, Responsibilities, Compliance, and Transparency

a. Establish a clear foundation for IBC authority and independence

We support the requirement for an IBC and encourage NIH to pair its responsibilities with explicit institutional authority, support, and independent decision-making. An "Establishing an IBC" subsection could provide a consistent foundation while allowing flexibility in institutional structure. We offer the following language for consideration:

> The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.
>
> As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

b. Distinguish substantive oversight from administrative support

Clearer separation of IBC oversight functions, committee procedures, and administrative tasks would help institutions assign work appropriately and support timely responses. Please consider specifying that the IBC's substantive responsibilities include:

- Reviewing the biosafety program, including practices, training, emergency preparedness, and continued compliance.
- Conducting or directing periodic, risk-based evaluations of facilities, equipment, and containment, with findings, deficiencies, and reasonable corrective plans and schedules reported to the Institutional Official or designee.

- Reviewing concerns, incidents, unsafe conditions, and noncompliance; requiring corrective measures; overseeing resolution; and recommending improvements to facilities, training, and resources.
- Approving, requiring modifications to secure approval, or withholding approval of covered activities and significant changes before implementation.
- Suspending or withdrawing approval and requiring cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

We also encourage flexibility for qualified staff to conduct evaluations under written institutional procedures, with intervals proportionate to risk and IBC responsibility retained for oversight determinations. The IBC would approve its minutes and substantive determinations, while staff could prepare, retain, redact, and post records; communicate decisions; track deadlines; and prepare authorized submissions.

Please also clarify immediate stop-work authority and subsequent IBC review. Qualified response teams need to be able to investigate and take immediate protective action without waiting for a committee meeting.

c. Align accountability with authority

The expanded responsibilities assigned to BSOs and IBCs would be more effective if accompanied by explicit access to facilities and relevant records, direct reporting and escalation pathways, and authority to require corrective measures and stop or suspend unsafe work when necessary. We ask NIH to make these authorities clear so that institutional personnel can fulfill the responsibilities the policy assigns to them.

d. Support experienced program leadership

We appreciate the draft's recognition of the Biological Safety Officer's role. Where BSO duties are assigned to another official, equivalent qualifications and institutional support remain essential.

Please consider requiring each covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to its research portfolio. Expectations for qualifications, institutional access, reporting relationships, resources, and escalation of unresolved risks would help institutions establish effective leadership. An official performing BSO duties would need equivalent qualifications for those duties.

Guidance on the relationships among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official would also be helpful. In particular, institutions would benefit from clarification of which roles may be combined, how independence is protected, and whether the BSO's IBC role includes program administration in addition to voting membership. We encourage NIH to emphasize experience and functional authority, comparable to other institutional oversight leaders such as animal welfare directors or institutional veterinarians, while allowing flexibility in titles and administrative placement.

e. Clarify occupational health and safety expectations

We welcome the recognition of occupational health and safety as part of an effective biosafety program. The draft notes that other regulations and policies may require an Occupational Health and Safety Program. Clear triggers, assigned authorities, and responsibility for developing and communicating required procedures would help institutions understand and coordinate these obligations.

f. Clarify committee governance

Additional guidance on quorum and voting would support consistent committee decisions. We ask NIH to specify that a member recused because of a conflict does not count toward the quorum for that matter and to explain the voting denominator after recusal.

Institutions would also welcome expectations for remote participation, use of ad hoc consultants, and reasonable approaches for institutions that have difficulty recruiting unaffiliated members.

g. Map retention requirements to record types

A record-retention table would be a practical aid to implementation. Please consider including protocols, risk assessments, delegated reviews, training, assurances, meeting minutes, incident reports, and records spanning multiple awards. Identifying the triggering event, retention period, public availability period, responsible custodian, and any superseding award or legal requirements would reduce uncertainty and inconsistent practice.

h. Provide a predictable Biosafety Assurance process

We appreciate the value of an institutional Biosafety Assurance and ask NIH to provide a standardized template and a predictable submission, approval, and renewal process. These resources would promote consistent submissions and help prevent interruptions during timely renewal.

A template could distinguish required, conditional, and optional fields and address institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. We encourage NIH to retain substantive obligations in the policy itself rather than introduce additional requirements through templates.

Please also specify required institutional signatures, the submission system, completeness criteria, and how timely renewals will be handled while NIH review is pending. Clarifying which information must be public and which may be submitted directly to NIH when public posting is inappropriate or unavailable would further support implementation.

5. Incident Reporting and Safety Learning

a. Preserve local management of lower-risk events

We support reporting that enables NIH to identify significant risks and strengthen biosafety. Please consider preserving local IBC management of lower-risk events and near misses, without requiring public posting of every internally reviewed minor event or unredacted identifying information. A

proportionate approach would support prompt reporting and corrective action while focusing federal reporting on events that warrant that level of oversight.

b. Use aggregate reporting to advance transparency and learning

UM supports appropriate transparency regarding biosafety incidents. We ask NIH to consider whether the proposed public information, even when direct identifiers are removed, could identify individuals through contextual details and raise concerns about disclosure of protected medical information. In areas that have historically attracted harassment or threats, including animal research, public disclosure of investigator identities, funding information, or other identifying details may also create risks for researchers and animal care personnel.

We encourage NIH to meet its transparency goals through aggregated, de-identified incident data, including an Annual Incident Summary Report and the National Biosafety Data and Safety Analysis Center (NBDSAC). Annual summaries of trends, contributing factors, and lessons learned could support shared learning without identifying individuals or institutions in routine, well-managed incidents. Full records could remain available to NIH and other authorized reviewers for investigations of laboratory-acquired infections and other public health purposes.

For a voluntary learning system to be effective, institutions and researchers need to understand its confidentiality protections, disclosure boundaries, and relationship to enforcement. Clear parameters would help build confidence in participation and improve the usefulness of the information collected.

c. Explain how investigator duties and reporting pathways interact

Section III-C assigns investigators safe-research responsibilities that intersect with institutionally managed facilities and services. We would welcome clarification of how these responsibilities are shared so investigators understand which actions they must take directly and which require institutional coordination.

Please also explain how confidential voluntary reporting to NBDSAC interacts with mandatory NIH reporting and public posting. Clear limits on confidentiality and a clear distinction between voluntary learning submissions and required reports would help institutions participate with an accurate understanding of their obligations.

6. Implementation Resources and Timeline

a. Provide practical implementation resources

We appreciate NIH's efforts to support institutions through this transition. The following resources would be particularly valuable before implementation begins:

- A Biosafety Assurance template and model institutional policies.
- Decision trees, risk-assessment forms, and worked examples.
- Training materials for IBC members, BSOs, PIs, and staff.
- Sample completed minutes and incident reports, with clear redaction guidance.
- A national Risk Group and containment determination database.
- Guidance for external, shared, and consortium IBC models.

Making these resources available with the final policy would help institutions develop consistent procedures and avoid repeated revisions as expectations become clearer.

b. Allow sufficient time for a coordinated transition

Implementing the proposed policy will require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research. We respectfully request at least 12 months for full implementation after final guidance and required templates are available.

Please consider staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, allowing conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work, would help institutions manage the transition effectively. Preserving staggered renewal cycles would also reduce avoidable backlogs.

Thank you for considering these recommendations and for inviting institutional input throughout the policy's development. UM supports NIH's biosafety goals and welcomes continued engagement to help develop a final policy that strengthens safety, supports consistent oversight, and can be implemented effectively across institutions with varied research portfolios and resources.

Summary of Comments on the Draft NIH Biosafety Policy

NIH Notice NOT-OD-26-112 | Draft policy for research involving biohazards | October 19, 2026

Purpose. This working summary identifies recommendations for strengthening the proposed policy with respect to emerging biotechnology, institutional oversight, and practical implementation. These are proposed comments, not requirements already established by NIH.

1. Address mirror life explicitly

Priority: High | Relevant draft sections: Sections II, IV-1, V-A, V-C

Clarify whether wholly or partially mirror-image biological systems fall within the definition of a biohazard or novel organism. Distinguish useful research on nonreplicating mirror-image molecules from work toward self-replicating mirror organisms. Provide a precautionary referral and assessment pathway for the latter, addressing uncertainty about biological interactions, environmental persistence, detection, and effective containment. Avoid assigning conventional Risk Groups without adequate evidence.

2. Modernize assessment of AI-designed and de novo biological systems

Priority: High | Relevant draft sections: Sections II, V-B, V-C

Explicitly address AI-designed proteins, genetic circuits, and organisms with no meaningful parental organism. Supplement sequence provenance and parental Risk Group considerations with functional, phenotype-based, context-dependent, and uncertainty-aware assessment. Treat lack of an identified hazardous parent as insufficient evidence of safety.

3. Define oversight for autonomous and AI-directed experiments

Priority: High | Relevant draft sections: Sections III-B, III-C, V-D, V-E

Specify how IBC-approved research applies when an automated or AI-driven system changes experimental parameters or selects subsequent experiments. Encourage defined, validated operating envelopes, pre-established escalation triggers, audit trails, safeguards against out-of-scope operations, and human authority to intervene. Require renewed review when changes materially alter risk.

4. Enable validated AI-assisted biosafety risk assessment

Priority: High | Relevant draft sections: Sections III-B, III-C, V

Recognize computational decision-support tools for literature synthesis, protocol triage, identification of missing hazard information, and documentation. Make clear that IBCs and investigators retain decision authority. Provide guidance on tool validation, evidence traceability, accuracy, uncertainty, confidentiality, and periodic reevaluation.

5. Build the National Biosafety Data and Safety Analysis Center as a scientific resource

Priority: High | Relevant draft sections: Sections II, III-C, III-D

Support the proposed center and develop standardized, interoperable incident and near-miss data fields, including exposure context, causal factors, process and equipment conditions, and corrective actions. Enable rigorous trend analysis while protecting confidentiality and guarding against re-identification. Account for reporting-culture differences before making comparisons among institutions.

6. Integrate cyberbiosecurity where digital compromise creates biological risk

Priority: High | Relevant draft sections: Sections III-A, III-B, V-D, V-E

Include proportionate evaluation of connected instruments, automated systems, electronic protocols, biological inventories, laboratory information systems, and facility controls. Clarify coordination with institutional cybersecurity teams, and when a digital incident that affects containment or safe experimental operation warrants biosafety investigation or reporting.

7. Clarify boundaries of biosafety, biosecurity, and dual-use oversight

Priority: Medium | Relevant draft sections: Sections II, III-B, IV

Explain referral and coordination mechanisms among IBCs, institutional research security functions, and applicable federal oversight frameworks. Do not imply that IBCs alone should adjudicate all dual-use or information-security issues. Avoid duplicate reviews and conflicting determinations.

8. Strengthen institutional implementation and proportional oversight

Priority: Medium | Relevant draft sections: Sections II, III-A, III-B, IV

Provide actionable criteria for delegated review and for determining when a protocol change requires reassessment. Evaluate the net workload associated with expanded coverage, Biosafety Assurances, three-year de novo reviews, incident reporting, and public posting. Supply standardized templates, training, transition support, and realistic workload assumptions.

9. Balance transparency with protection of sensitive information

Priority: Medium | Relevant draft sections: Sections III-A, III-B

Clarify redaction criteria for IBC minutes and incident reports. Protect confidential research details, individual privacy, physical security vulnerabilities, and sensitive operational information while ensuring meaningful public accountability. Provide consistent examples and a process for resolving disclosure disagreements.

10. Clarify environmental and nonhuman risk boundaries

Priority: Medium | Relevant draft sections: Sections II, V-A, V-B, V-E

Resolve the tension between a scope centered on human health and risk assessments that also consider ecological and nonhuman impacts. Explain handling of gene-drive systems and other novel synthetic organisms for which environmental effects may be central, including where field-release activities fall outside this laboratory-focused policy.

Overall recommendation

Retain the proposed expansion from recombinant-DNA-focused guidance to risk-based oversight of biohazards. Strengthen it with forward-looking provisions for novel biological architectures, AI-enabled design and experimentation, and digitally connected laboratories. Pair these provisions with scientifically grounded, proportionate review procedures and a national learning system for biosafety incidents and near misses.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): arlington

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Public Posting Requirements Create Significant Administrative Burden

Observation
The proposed transparency requirements represent a substantial expansion of public disclosure obligations compared with the historical framework.
Transparency is important and can strengthen public trust. However, the operational burden associated with public posting requirements should not be underestimated.

Real-World Implementation Impact
Public posting involves far more than publishing documents online.
Before posting materials, institutions may need to:
• Conduct privacy reviews;
• Conduct security reviews;
• Redact sensitive information;
• Review employment and student information;
• Evaluate proprietary research information;
• Address legal considerations;
• Maintain public websites; and
• Retain records over time.

For biosafety programs with limited staffing, these responsibilities will often be managed by the same individuals responsible for:
• Protocol review;
• Laboratory inspections;
• Risk assessments;
• Incident response; and

• Investigator support.
Every hour devoted to preparing public-facing documents is an hour unavailable for direct biosafety activities. For example, in my professional capacity, I will devote a minimum of eight work hours to preparing meeting minutes that are publicly available.

Why This Matters
The question is not whether transparency is valuable.
The question is whether implementation requirements are calibrated in a way that allows institutions to achieve transparency objectives without weakening operational biosafety functions.
Particularly at smaller institutions, additional administrative obligations may disproportionately affect available biosafety resources.

Recommendation
NIH should:
1. Develop written redaction guidance, not simply such as examples.
2. Create model posting procedures.
3. Clarify confidentiality expectations.
These measures would support transparency while reducing implementation burden.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

443. Marie-Luise Faber

I am responding: On behalf of myself

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed guidelines as currently written will bring research to a halt! The proposed scope is unattainable for any decently sized research institution. The request to review and renew the current NIH Guidelines was to use the expertise of the biosafety professionals in the field that oversee use of organisms in the lab. The ask was to remove oversight over organisms that are not considered a risk. The proposal increases the oversight by volumes without any increased safety or security to our researchers!

Can a blanket registration be submitted per institution for material where the risk level doesn't change, regardless of modification?

What is the benefit to registering all transgenic mice. The request during the listening sessions was to stop having to register lower risk organisms that cannot have an effect on environment or cause human disease. Instead of exempting drosophila, you now have added millions of transgenic mouse strains. What is the risk of these transgenic mice? How does one even do a risk assessment from one transgenic mouse to another, when they are all housed at ABSL-1? Will NIH provide training and guidance to BSOs on how to perform a comprehensive risk assessment on transgenic mice? I've been doing this for 16 years and won't know where to start!

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: For downgrades for RG3 and RG4 organisms to lower levels: Can other institutions use these approved downgrades that were issued to a single institution? What about downgrades that the local IBC approved in the past, will those be grandfathered in or do such requests now need to be resubmitted to NIH for approval?

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposal states that records must be retained 3 years past the submission of an award's final financial report. The

problem with this is that the minutes tied to this submission will also have to retained past the 5 years that they are posted on an institution's website. The administrative burden to link, find, and maintain all the minutes tied to a grant (or often multiple grants) will be huge. What happens when the PI leaves the institution, but the grant still exists, just with another institution? Does the previous institution need to continue to retain those records?

6. Other feedback relevant to this resource: Escalation of biosafety oversight without any additional funding or support will be unfeasible to attain. Implementing this proposed policy as written will be a huge burden on biosafety professionals, and will decrease the time they have available to perform vital biosafety assessments that are not captured in this policy. The addition of an overwhelming amount of oversight on material that is either low risk or, like in human cells, the risk doesn't change from one version to another, just has no added value to biosafety. Additionally, the proposed policy is poorly written, with many of the items mentioned not clearly defined or not defined at all, as in the case of DGMO.

444. Ericka E. Pearce

I am responding: On behalf of myself

Name: Ericka E. Pearce

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): arlington

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Incident Reporting Requirements Should Be Harmonized With Existing Federal Reporting Systems

Observation
The draft introduces new incident-reporting requirements that may overlap with existing federal reporting obligations.
Many research institutions already report certain incidents through established pathways involving other federal agencies.

Real-World Implementation Impact
When a laboratory incident occurs, biosafety personnel must immediately focus on:
• Exposure assessment;
• Medical evaluation;
• Laboratory containment;
• Corrective actions;
• Follow-up investigations;
• Stakeholder communications; and
• Regulatory notifications.
In a recent incident response in which I participated, biosafety personnel spent several days coordinating

exposures assessments, communications, corrective actions, and follow-up activities.

Additional reporting obligations may require personnel to prepare multiple reports containing substantially similar information for different recipients.
This effort occurs during the same period when immediate response activities are most critical.

Why This Matters
Duplicative reporting may increase administrative burden without improving safety outcomes.
It can also create opportunities for inconsistencies if multiple reports are prepared independently for different agencies.
Resources dedicated to repetitive reporting are resources unavailable for incident mitigation and prevention activities.

Recommendation
NIH should:
1. Harmonize reporting requirements with existing federal programs (one example is the FSAP Form 3 reporting process).
2. Accept equivalent reports where appropriate.
3. Develop cross-reporting mechanisms.
4. Eliminate duplicative information requests.
5. Clarify how public posting requirements interact with existing reporting frameworks.
The most effective incident-reporting systems maximize learning and accountability at the institutional level while minimizing unnecessary duplication.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Federal vs. Local Oversight for Emerging, Novel, and Unclassified Agents

Observation
The draft requires NIH involvement for certain emerging, novel, or unclassified agents while also emphasizing institutional risk assessment.

Real-World Implementation Impact
In practice, IBCs and biosafety professionals will frequently encounter agents for which no explicit BMBL containment recommendation exists. Many institutions may feel obligated to seek NIH review out of caution, even for agents that are routinely handled safely under existing frameworks.

Why This Matters
The absence of clear thresholds may increase requests for federal review, create delays, and reduce the efficiency of local risk assessment processes.

Recommendation
NIH should provide objective criteria, examples, and decision trees identifying when local review is sufficient and when federal review is required.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Renewal and De Novo Review Pathways Require Clarification

Observation
The draft does not clearly explain how de novo renewals interact with delegated review pathways.

Real-World Implementation Impact
Protocols that initially qualified for delegated review may be routed to full committee review solely because they are undergoing renewal.

Why This Matters
The review pathway should be driven by risk rather than administrative timing.

Recommendation
NIH should clarify whether renewals follow the same review pathway as the underlying activity.

447. Joanie Ryan

I am responding: On behalf of myself

Name: Joanie Ryan

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Role - Other: Biosafety Professional

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy scope needs to be clarified to ensure it applies consistently across all research settings involving biological hazards, not just laboratory environments. As written, the scope may be interpreted as excluding activities conducted in animal facilities, greenhouses, agricultural settings, field studies, and other nonlaboratory environments where biological hazards are present.

The definition of covered biohazards should also extend beyond agents that cause disease in humans. Biological agents may present meaningful risks to human, animal, plant, or environmental health without causing human disease. Coverage should be based on risk rather than human pathogenicity alone.

In addition, exclusion of plants may create oversight gaps. Clarification is needed regarding how genetically modified plants, plant pathogens, plant-associated toxins, agricultural pests, and related organisms will be addressed. A comprehensive biosafety framework should reflect a One Health approach that considers human, animal, plant, and environmental health impacts.

Several definitions also require additional clarification to reduce subjective interpretation and promote consistent implementation. For example, it is unclear whether the term "toxins" refers only to biological toxins or to all toxic substances, and whether "prions" includes prion diseases affecting nonhuman species. A glossary or cross-reference to established definitions would improve consistency and reduce ambiguity across institutions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The ideal risk-based oversight framework reserves federal reporting and review requirements for activities presenting the greatest potential risk while allowing institutions flexibility to manage lower-risk activities locally.

Additional clarification is needed regarding the distinction between reportable incidents, compliance

violations, and events that can be managed through institutional corrective action processes. A tiered approach to incident reporting would help focus federal oversight on significant events while reducing administrative burden associated with minor incidents that do not involve exposure, environmental release, or increased risk.

The policy should also clarify whether all protocol renewals require the same level of review or whether continuing review requirements can be commensurate with risk and program changes.

3. Continued utility of Risk Groups: Risk Groups continue to provide useful baseline information regarding the intrinsic hazards associated with biological agents and remain valuable as an initial component of risk assessment. They provide a common language from which to start.

However, Risk Groups alone do not adequately address risks associated with genetically modified organisms, novel constructs, altered host range, modified virulence, toxin production, or other engineered characteristics. Institutional risk assessments should continue to consider both the agent and the specific experimental manipulations being performed.

Additional guidance is needed regarding how institutions should determine risk groups under the proposed framework, particularly because the draft does not appear to identify whether information currently provided in Appendix B of the NIH Guidelines will continue to be maintained. BMBL does not include risk groups, and in some cases provides a BSL range. Clear guidance regarding the relationship between Risk Groups, project-specific risk assessment, and Biosafety Levels would improve consistency across institutions.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Many institutions already apply biosafety principles to activities beyond those explicitly required by regulation or funding conditions. NIH can encourage broader adoption by providing practical tools, templates, decision trees, training resources, and examples that can be implemented regardless of funding source.

The policy should emphasize education, technical assistance, and model practices rather than creating the perception that voluntary adoption may result in additional reporting obligations or enforcement consequences. Institutions are more likely to voluntarily align with NIH expectations when resources are clear, accessible, and scalable to programs of varying sizes.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The incident reporting template would benefit from clearer reporting thresholds and definitions. Additional guidance is needed regarding whether incidents such as spills contained within primary containment, minor events without exposure or release, or needlesticks involving sterile needles require reporting at each BSL (eg sterile needlestick BSL-3).

Clarification is also needed regarding:

Whether "within 24 hours" refers to calendar hours or business hours;
Whether the incident reporting template is required for events that are not NIH-reportable;
How submitted incident information may be used in compliance, enforcement, or funding decisions.

The meeting-minutes template appears to require documentation that many institutions already maintain in separate records, including risk assessments, training documentation, inspections, occupational health records, and compliance activities. Requiring this information to be duplicated in meeting minutes significantly increases administrative burden without improving oversight. Institutions should be permitted to reference existing records whenever appropriate.

Additionally, public posting of incident reports with the proposed information included will discourage reporting and undermine safety culture if personnel become concerned about privacy, reputational impacts, litigation risk, or other unintended consequences. Careful consideration should be given to de-identification standards, redaction requirements, aggregation of minor events, and protections for security-sensitive information.

6. Other feedback relevant to this resource: The proposed implementation timeline will be challenging for institutions that must revise policies, train personnel, submit assurances, and review existing research activities. A phased implementation process would facilitate compliance while minimizing disruption to ongoing research.

Additional guidance would be beneficial in the following areas:

Definitions of key terms, including incident, compliance violation, failure to maintain IBC approval, toxin, and prion.
Determination of Risk Groups and Biosafety Levels under the new policy framework.
Expectations for protocol renewals and continuing review.
Incident-reporting thresholds and examples of reportable versus non-reportable events.
NIH review timelines for Biosafety Assurances, containment determinations, requests to lower containment levels, and incident reviews.
Transitional or provisional mechanisms for institutions awaiting NIH review.

A consolidated glossary of policy terms and decision-making examples would improve consistency of implementation and reduce variability in interpretation across institutions. Published response-time expectations and status-tracking processes would also help institutions plan and prioritize submissions while maintaining ongoing research operations.

448. Jonathan A Javitch

I am responding: On behalf of myself

Name: Jonathan A Javitch

Name of Organization:

Type of Organization: Academic Institution

Description: Overall assessment of the proposal and related issues.

Public Comment on the Draft NIH Biosafety Policy for Research Involving Biohazards
Notice NOT-OD-26-112 · Federal Register, September 14, 2026

I am a neuroscientist at Columbia University, where I direct the Division of Preclinical Research at the New York State Psychiatric Institute. My laboratory studies the molecular mechanisms of G protein-coupled receptors, including dopamine, opioid, and metabotropic glutamate receptors, from purified protein through cultured cells to behaving mice. We routinely express receptors in cultured cell lines, express proteins in *E. coli* and yeast, deliver constructs with adeno-associated viral vectors into mouse brain, use bacterial toxins that are not Select Agents, and maintain multiple transgenic mouse lines at ABSL-1. Under the current NIH Guidelines, nearly all of that work is either exempt or requires only notice to our IBC at the time it begins.

I am not writing to argue against biosafety oversight. The Guidelines are organized around recombinant nucleic acids, so work with wild-type pathogens and with toxins falls outside them, and bringing that work under a single policy is reasonable.

I am writing because the draft, read as written, brings a large body of work that poses no credible risk to human health under committee review, and because the terms meant to limit its reach are left undefined or poorly defined, which will lead to differences in interpretation and inconsistent application.

The Policy's scope turns on a phrase that is not defined

The draft defines genetic modification to include introducing into cells, organisms, or viruses nucleic acid that "can be transcribed or translated." Transfecting HEK293 cells with a receptor cDNA, expressing a receptor fragment in *E. coli*, and making a reporter strain in yeast all meet that definition.

What keeps that definition from reaching the whole of molecular biology is its qualifier: research involving biohazards is research carrying "known or potential risk to human health." Reviewing work that carries real risk to human health is reasonable, and I am not arguing otherwise. The difficulty is that "potential risk" is nowhere defined, and the activities I have listed carry no meaningful risk at all.

Each IBC will therefore draw the line somewhere of its own, and identical experiments will be exempt at one institution and registered at another.

The Guidelines drew that line explicitly. Section III-F and Appendix C exempt the *E. coli* K-12 and *S. cerevisiae* host-vector systems, tissue-culture work with characterized cell lines, and the breeding of transgenic rodents at BSL-1. The draft has no counterpart to any of them, and delegated review is not an exemption: work in that tier still requires a registration, an amendment when the work changes, and de novo review every three years.

I urge NIH to define "potential risk to human health," or to publish a list of activities presumptively outside the Policy, and to carry explicit exclusions into the final policy for the activities now exempt under Section III-F and Appendix C.

The vector tier is drawn on integration, which is not strictly where the risk is

Delegated review covers "replication incompetent, nonintegrating viral vectors expressing reporter or low risk transgenes."

Integration is an inadequate proxy for hazard. A replication-incompetent vector that integrates and carries a fluorescent sensor is less hazardous than many non-integrating vectors carrying biologically active genes. Third-generation lentiviral vectors are replication-incompetent, are handled at BSL-2, and are in routine use across neuroscience, but because they integrate, this wording puts them outside the delegated tier and into full committee review.

"Low risk transgene" is also undefined.

We screen AAV serotypes for tropism, and the draft does not say whether substituting a capsid, with no change to the transgene, requires new review.

I urge NIH to define the tier by replication competence together with transgene hazard, to define "low risk transgene," and to state whether serotype or capsid substitution alone triggers re-review.

The draft does not say what a registration covers

The draft requires that "any changes to the approved research that have the potential impact on the original biosafety assessment must be reviewed and approved by the IBC, or its delegate, before such research is conducted." It does not say whether a registration is per project, per agent, or per award, and it gives no examples of changes that meet that threshold.

A single project in my laboratory may use one viral vector, one bacterial toxin, and multiple mouse lines. Each element is individually low risk and individually delegable. Whether that project is one registration or several, and whether adding a line or a construct requires approval before the work starts, determines whether the project is registered once or returns to the committee each time it changes.

The Policy bars any covered research before IBC approval. Work that today requires only notice to the IBC when it begins, under Section III-E, and work that is exempt under Appendix C would both move behind prior approval, so experimental timing would depend on committee turnaround. The draft sets no turnaround requirement for delegated review; a delegated approval need only be reported to the IBC at its next scheduled meeting.

I urge NIH to state what a registration covers, to give examples of changes that require re-review, and to set an expected turnaround for delegated review.

Public posting and 24-hour reporting are substantial obligations that have not been tested

The draft would have institutions post approved IBC minutes and all incident reports on a public webpage, and notify NIH within 24 hours of learning of an incident posing significant risk to human health.

The draft does not say what starts the 24-hour clock. The facts of an incident are often unclear for the first day or two.

Minutes are useful to a committee because members say plainly what they think might go wrong. Minutes written for publication are written differently.

I urge NIH to assess both requirements at a subset of institutions before applying them everywhere.

I ask NIH to define the terms that set the Policy's scope, and to carry the existing exemptions forward.

Thank you for considering these comments.

Jonathan A. Javitch, M.D., Ph.D.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy goes beyond the initial scope of the policy listed in Section I of the proposal. There is little clarity on what exactly should be included in the registrations or not. Oddly enough, recombinant plant material is now excluded, though risk of release of recombinant plant could be detrimental to US agriculture.
What are recombinant plants being removed from the oversight of this policy? While this material may not be hazardous to humans directly but could very well affect local and global agriculture. Is it enough to capture recombinant plants under USDA permits where biosafety professionals do not have access to applications or knowledge of what researchers are working with?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Why can't an existing registration be renewed after 3 years? What is the purpose of requiring a de novo registration? Currently my institution uses online platform where renewing an existing registration will copy it to a new entry with a new IBC number. Is a straight copy of an existing registration acceptable when generating a "de novo" renewal?

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The notification of a potential LAI is unattainable. If an institution works with influenza and staff at that institution get sick with flu, does the institution have to test if it's the same strain. Do all flu cases at an institution have to be reported? Or only from staff in the lab setting? This would also force all staff to self-report. Many people may get sick with a common cold and just stay home and not see a doctor or report anything, knowing it will pass in a few days.

6. Other feedback relevant to this resource: Is material that has been in ownership at an institution grandfathered in? Do institutions that have not had to register material, but now included in the policy,

need to go back and register such past material already in ownership or only newly acquired material that now falls under the policy?

450. American Society of Gene and Cell Therapy (ASGCT)

I am responding: On behalf of an organization

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Cell and Gene Therapy

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: ASGCT encourages NIH to clarify the proposed definition of "genetic modification" to ensure it accurately reflects the range of technologies and research activities covered by the policy. As currently written, the definition includes the introduction of nucleic acids that "can be transcribed or translated," without clearly distinguishing between technologies that permanently alter the genome and those that do not.

This broad language could create confusion regarding the classification of certain technologies, including mRNA-based products, non-integrating gene therapies, and other approaches that introduce genetic material without permanently modifying a recipient's genome. While these technologies that do not modify the genome may warrant appropriate biosafety oversight, the terminology used to describe them should accurately reflect their biological characteristics and intended applications.

ASGCT urges NIH to refine this definition or provide accompanying clarification that distinguishes between the introduction or expression of genetic material, and permanent changes to the genome. Such clarification would help ensure consistent interpretation of the policy while avoiding confusion among researchers, policymakers, and the public. Clear, scientifically grounded terminology is particularly important to maintain public understanding and confidence in emerging biomedical technologies.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Allowing certain activities to undergo delegated Institutional Biosafety Committee (IBC) review could reduce unnecessary administrative burden while maintaining appropriate safety protections. As NIH considers this approach, ASGCT encourages the Institutes to ensure that oversight requirements reflect the actual risks of individual technologies and research activities. CGT research encompasses a broad range of approaches, including viral vectors, genetically modified cells, and other emerging platforms with distinct characteristics and safety profiles. , Oversight requirements should account for established scientific evidence, prior safety data, and modifications specifically designed to reduce risk, ensuring that the level

of review is proportional to the risks of the research – rather than determined solely by broad technology classifications.

ASGCT also encourages NIH to clarify how the proposed oversight framework would interact with existing institutional and FDA requirements for CGT clinical research. Clear expectations and coordination across oversight bodies will be important to avoid unnecessary duplication or delays while maintaining rigorous safety standards.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): ASGCT recognizes the importance of institutional accountability and appropriate enforcement mechanisms to maintain strong biosafety standards. However, the proposed policy's broad scope, coupled with provisions allowing noncompliance to affect current and future NIH funding, raises concerns about the potential consequences of unclear or inconsistently interpreted requirements.

The proposal states that institutions receiving NIH funding must ensure compliance for research conducted or sponsored by the institution, regardless of the individual research project's funding source. It further provides that noncompliance may result in additional funding conditions, termination of awards, or impacts on future funding decisions. Biomedical research programs often require years of continuous effort before meaningful outcomes can be achieved. Long-term preclinical studies, specialized manufacturing facilities, multi-year clinical trials, longitudinal patient follow-up, and complex public-private partnerships cannot be paused and restarted without serious impact on patient participants and institutions. For CGTs, where a single program may span a decade from IND filing to BLA approval, , mid-stream terminations do not merely delay results. They can end programs entirely. Although similar institutional compliance obligations and funding-related enforcement mechanisms exist under the current Guidelines, the expanded scope of the proposed policy, coupled with the longer development timelines associated with CGTs, makes it especially important that institutions have a clear understanding of their responsibilities.

Without sufficient detail regarding how the new requirements will be interpreted and enforced, researchers and institutions may face uncertainty about whether established practices remain compliant. This uncertainty could discourage research activities, create unnecessary administrative burden, or disrupt ongoing projects, even where there is no meaningful change in biosafety risk. Nearly every FDA-approved CGT available to patients today traces its origins to decades of federally supported scientific research. Maintaining consistency and predictability in federal research funding is essential to sustain the basic research that has helped produce today’s pipeline of more than 4,400 therapies.

ASGCT therefore encourages NIH to establish clear, consistent, and transparent compliance standards before implementing any new policy. Enforcement should be proportional to the nature and severity of a violation, with appropriate opportunities for institutions to identify and correct deficiencies. An explicit appeals process would help mitigate some of the uncertainty around the policy’s implementation. Given that the detailed examples and guidance in the current Guidelines would be removed, NIH should ensure that any appeals process is clearly defined and fully transparent. NIH should also clarify how compliance

concerns involving individual research activities would be evaluated and ensure enforcement actions do not unnecessarily jeopardize unrelated programs or funding under an institution's broader research portfolio.

These safeguards would help ensure that biosafety oversight remains focused on protecting researchers and the public while providing institutions with the predictability needed to plan and conduct biomedical research.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: ASGCT is concerned that the proposed policy substantially reduces the level of detail contained in the Guidelines. Currently, there are extensive examples, definitions, and specific requirements that researchers and institutions have relied upon to determine appropriate biosafety practices. While a more streamlined policy may offer some benefit, removing this detail without providing comparable guidance could create uncertainty regarding how established research activities will be evaluated under the new framework.

For CGT researchers, this uncertainty may be particularly consequential given the diversity of technologies and research approaches used across the field. ASGCT encourages NIH to retain or replace the practical examples and technical guidance provided under the existing Guidelines, including clear explanations of how the new requirements apply to research already being conducted. Broad or opaque application of the new guidelines may discourage institutions from undertaking ambitious, high-investment projects. It could make it harder to attract partnerships that translate federal discoveries into domestic manufacturing. The more limited detail in this new policy could be particularly damaging to emerging investigators and early-career scientists, who may require more guidance on emerging technologies and best practices. In particular, NIH should issue implementation resources that clarify whether and how established research practices will be affected by the transition to the new policy.

Finally, ASGCT reemphasizes the importance of providing sufficient implementation guidance before the new policy takes effect. We encourage NIH to make these materials available for public review before finalizing or implementing the policy, particularly where they will determine how existing research practices are classified and overseen. Detailed examples, frequently asked questions, and guidance addressing common CGT research activities would help institutions prepare for the transition. NIH should also consider whether the proposed six-month implementation period provides sufficient time for institutions to evaluate existing research, update procedures, and ensure compliance without interrupting ongoing studies.

Re: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Sir/Madam,

The American Society of Gene & Cell Therapy (ASGCT) appreciates the opportunity to provide comments on the National Institutes of Health's (NIH) *Draft Biosafety Policy for Research Involving Biohazards* (NOT-OD-26-112).

ASGCT is a nonprofit professional membership organization comprised of more than 7,300 scientists, physicians, patient advocates, and other professionals working on cell and gene therapies (CGTs) in settings such as universities, hospitals, and biotechnology companies. The mission of ASGCT is to advance knowledge, awareness, and education that leads to the discovery and clinical application of genetic and cellular therapies to alleviate human disease.

ASGCT acknowledges NIH's stated objectives to modernize biosafety oversight, strengthen research safety, and establish requirements that reflect the evolving biomedical research landscape. We recognize the value of a risk-based oversight framework that maintains appropriate safeguards while reducing unnecessary administrative burden for lower-risk research. However, as NIH considers replacing its longstanding *Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules* ("Guidelines"),[1] ASGCT encourages the agency to provide greater clarity regarding the scope and application of the proposed policy, particularly for established research practices and emerging CGT technologies covered by the Guidelines.

Our comments focus on the need for clear, scientifically grounded definitions, consistent compliance expectations, and sufficient implementation guidance to ensure that the new framework supports safe research without introducing unnecessary uncertainty or disruptions to ongoing scientific work.

We offer the following comments regarding the new proposed policy, should replacement Guidelines be finalized:

[1] National Institutes of Health, Office of Science Policy (2024 April). *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules*. https://osp.od.nih.gov/wp-content/uploads/NIH_Guidelines.pdf

1. **Scope of research covered by the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.**

ASGCT encourages NIH to clarify the proposed definition of "genetic modification" to ensure it accurately reflects the range of technologies and research activities covered by the policy. As currently written, the definition includes the introduction of nucleic acids that "can be transcribed or translated,"[2] without clearly distinguishing between technologies that permanently alter the genome and those that do not.

This broad language could create confusion regarding the classification of certain technologies, including mRNA-based products, non-integrating gene therapies, and other approaches that introduce genetic material without permanently modifying a recipient's genome. While these technologies that do not modify the genome may warrant appropriate biosafety oversight, the terminology used to describe them should accurately reflect their biological characteristics and intended applications.

ASGCT urges NIH to refine this definition or provide accompanying clarification that distinguishes between the introduction or expression of genetic material, and permanent changes to the genome. Such clarification would help ensure consistent interpretation of the policy while avoiding confusion among researchers, policymakers, and the public. Clear, scientifically grounded terminology is particularly important to maintain public understanding and confidence in emerging biomedical technologies.

2. **Structure of tiered oversight (i.e., Federal, institutional, and investigator), including appropriateness in terms of calibration to risk, accountability measures, transparency, and streamlining of administrative burden, etc.**

Allowing certain activities to undergo delegated Institutional Biosafety Committee (IBC) review could reduce unnecessary administrative burden while maintaining appropriate safety protections. As NIH considers this approach, ASGCT encourages the Institutes to ensure that oversight requirements reflect the actual risks of individual technologies and research activities. CGT research encompasses a broad range of approaches, including viral vectors, genetically modified cells, and other emerging platforms with distinct characteristics and safety profiles.[3,4] Oversight requirements should account for established scientific evidence, prior safety data, and modifications specifically designed to reduce risk, ensuring that the level of review is proportional to the risks of the research – rather than determined solely by broad technology classifications.

Mutagen. 896.* https://pubmed.ncbi.nlm.nih.gov/38821669/

ASGCT also encourages NIH to clarify how the proposed oversight framework would interact with existing institutional and FDA requirements for CGT clinical research.[5] Clear expectations and coordination across oversight bodies will be important to avoid unnecessary duplication or delays while maintaining rigorous safety standards.

4. **Effectiveness of compliance and enforcement mechanisms for ensuring biosafety, including strategies for encouraging voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions), and addressing any biosecurity challenges.**

ASGCT recognizes the importance of institutional accountability and appropriate enforcement mechanisms to maintain strong biosafety standards. However, the proposed policy's broad scope, coupled with provisions allowing noncompliance to affect current and future NIH funding, raises concerns about the potential consequences of unclear or inconsistently interpreted requirements.

The proposal states that institutions receiving NIH funding must ensure compliance for research conducted or sponsored by the institution, regardless of the individual research project's funding source. It further provides that noncompliance may result in additional funding conditions, termination of awards, or impacts on future funding decisions. Biomedical research programs often require years of continuous effort before meaningful outcomes can be achieved. Long-term preclinical studies, specialized manufacturing facilities, multi-year clinical trials, longitudinal patient follow-up, and complex public-private partnerships cannot be paused and restarted without serious impact on patient participants and institutions. For CGTs, where a single program may span a decade from IND filing to BLA approval,[6,7] mid-stream terminations do not merely delay results. They can end programs entirely. Although similar institutional compliance obligations and funding-related enforcement mechanisms exist under the current Guidelines, the expanded scope of the proposed policy, coupled with the longer development timelines associated with CGTs, makes it especially important that institutions have a clear understanding of their responsibilities.

Without sufficient detail regarding how the new requirements will be interpreted and enforced, researchers and institutions may face uncertainty about whether established practices remain compliant. This uncertainty could discourage research activities, create unnecessary administrative burden, or disrupt ongoing projects, even where there is no meaningful change in biosafety risk. Nearly every FDA-approved CGT available to patients today traces its origins to decades of federally supported scientific research.[8] Maintaining consistency and predictability in

federal research funding is essential to sustain the basic research that has helped produce today's pipeline of more than 4,400 therapies.[9]

ASGCT therefore encourages NIH to establish clear, consistent, and transparent compliance standards *before* implementing any new policy. Enforcement should be proportional to the nature and severity of a violation, with appropriate opportunities for institutions to identify and correct deficiencies. An explicit appeals process would help mitigate some of the uncertainty around the policy's implementation. Given that the detailed examples and guidance in the current Guidelines would be removed, NIH should ensure that any appeals process is clearly defined and fully transparent. NIH should also clarify how compliance concerns involving individual research activities would be evaluated and ensure enforcement actions do not unnecessarily jeopardize unrelated programs or funding under an institution's broader research portfolio.

These safeguards would help ensure that biosafety oversight remains focused on protecting researchers and the public while providing institutions with the predictability needed to plan and conduct biomedical research.

5. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

ASGCT is concerned that the proposed policy substantially reduces the level of detail contained in the Guidelines. Currently, there are extensive examples, definitions, and specific requirements that researchers and institutions have relied upon to determine appropriate biosafety practices. While a more streamlined policy may offer some benefit, removing this detail without providing comparable guidance could create uncertainty regarding how established research activities will be evaluated under the new framework.

For CGT researchers, this uncertainty may be particularly consequential given the diversity of technologies and research approaches used across the field. ASGCT encourages NIH to retain or replace the practical examples and technical guidance provided under the existing Guidelines, including clear explanations of how the new requirements apply to research already being conducted. Broad or opaque application of the new guidelines may discourage institutions from undertaking ambitious, high-investment projects. It could make it harder to attract partnerships that translate federal discoveries into domestic manufacturing. The more limited detail in this new policy could be particularly damaging to emerging investigators and early-career scientists, who may require more guidance on emerging technologies and best practices. In particular, NIH should issue implementation resources that clarify whether and how established research practices will be affected by the transition to the new policy.

Finally, ASGCT reemphasizes the importance of providing sufficient implementation guidance *before* the new policy takes effect. We encourage NIH to make these materials available for public review before finalizing or implementing the policy, particularly where they will determine how existing research practices are classified and overseen. Detailed examples, frequently asked questions, and guidance addressing common CGT research activities would help

[9] American Society of Gene and Cell Therapy, Citeline (2026). Gene, Cell, & RNA Therapy Landscape Report: Q2 2026 Quarterly Data Report. https://www.asgct.org/uploads/files/general/Final-ASGCT-Citeline-Q2-2026.pdf

institutions prepare for the transition. NIH should also consider whether the proposed six-month implementation period provides sufficient time for institutions to evaluate existing research, update procedures, and ensure compliance without interrupting ongoing studies.

Conclusion

ASGCT recognizes NIH's efforts to modernize biosafety oversight and the importance of maintaining appropriate protections for researchers, patients, and the public. Any updated framework should provide clear, scientifically grounded expectations that reflect advances in biomedical research - while allowing established and emerging technologies to be evaluated according to their actual risks.

As NIH reviews feedback on the proposed new policy, ASGCT urges the agency to clarify the definition of genetic modification, preserve practical guidance for established research activities, and establish transparent, proportional compliance and enforcement expectations. We further encourage NIH to engage with researchers, institutional biosafety professionals, and other stakeholders to ensure that the final policy and accompanying implementation resources are clear, workable, and supportive of continued scientific innovation.

ASGCT appreciates the opportunity to provide these comments and looks forward to continued engagement with NIH on policies that support safe, responsible, and innovative biomedical research. If you would like to hear more from ASGCT's member experts, please reach out to Caitlin McCombs, ASGCT's public policy manager at cmccombs@asgct.org.

Sincerely,

David Barrett, JD, MS

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definition of the IBC is not clear, nor is where in the institution it should be house and who at the institution has responsibility and oversight. Who is the AOR and what qualifications do they need? What responsibility or liability of the AOR? Is this a personal liability or that of the institution?

Also, what is GDMO? This is defined nowhere in the proposal. Please make sure all acronyms are spelled out at least once and new or jargon language is defined.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Minor spills of low-risk agents, that do not involve a breach of containment and that were properly cleaned and decontaminated, generally do not need to be reported. What is the volume of a spill is more than "minor spill" that would now have to be reported? Is any spill small enough to be cleaned up by the lab or housekeeping considered minor? At what point is a spill not minor? What is breach of containment, what containment is considered here, a biosafety cabinet, a tube, a room with directional air-flow?

6. Other feedback relevant to this resource: A 6 month implementation period is not feasible! 6 months to roll the new policy requirements into our current registration systems, even if us biosafety professionals were to work on this and nothing else is just not attainable. Working just on this update would probably take more like a year or longer. However, we all have daily job tasks that have to been completed. Implementing the new policy and updating system will take 2+ years.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The registration of a genetic modification into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means is not practical nor does it serve any purpose to strengthen biosafety. A researcher may not even be aware that a passage of a cell has made a genetic modification. Sometimes these modifications will kill the cell or the virus outright and can't be documents. Sometimes they destroy the function of the organism and are therefore trashed. How can something that no longer exists or only exists a short time be captured in a registration? Genetic modification by chemical or radiological means is not currently under the prevue of biosafety. If the policy is to keep this requirement, will the government provide education and instruction to biosafety professionals on assessing such modifications, since many in the field do not have a strong chemistry background or have used radiation?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The mandatory use of a meeting minutes template appears to be regulatory overreach. IBCs have successfully exercised local oversight, accountability, and self-governance for decades. Any concerns with government labs should not be overlayed on academic institutions. Academic institutions should retain flexibility in how they document committee deliberations, provided required elements are captured. This shifts away from a performance-based approach toward unnecessarily prescriptive administrative requirements with little clear benefit to biosafety and biosecurity. Additionally, one size does not fit all and one mandatory template will not work for small and large institutions, private companies, etc.

Uploaded File: JR-Comments-on-the-Draft-NIH-Biosafety-Policy.docx

To whom it may concern:

I appreciate the opportunity to comment on the proposed NIH Biosafety Policy for Research Involving Biohazards. As an institutional biosafety professional and Chair of an Institutional Biosafety Committee, I support NIH's efforts to modernize biosafety oversight and establish a more comprehensive, risk-based framework for biological research.

However, I have significant concerns that several provisions of the proposed policy could unintentionally undermine effective biosafety programs by increasing administrative oversight of routine research and, more importantly, discouraging open communication between researchers and institutional biosafety professionals.

Public Incident Reporting and the Potential Impact on Safety Culture

My greatest concern with the proposed policy is the requirement for institutions to publicly post biosafety incident reports, including reports for incidents that do not meet the threshold for reporting to NIH.

In my experience, one of the most important elements of an effective biosafety program is the relationship between the biosafety office and the research community. Researchers need to feel comfortable contacting Safety when something goes wrong, when they have a question, or when they are uncertain whether an incident presents a potential hazard.

I work to foster an environment where researchers view the biosafety office as a resource and partner rather than simply a regulatory enforcement function. I want researchers to contact us when they experience an exposure, spill, procedural error, equipment failure, or near miss. These conversations provide opportunities to evaluate risks, implement corrective actions, and prevent future incidents.

I am deeply concerned that the proposed public incident-reporting requirements could damage this relationship.

The proposed reporting template includes the Principal Investigator's name and associated NIH grant information. Although individual laboratory personnel should not be identified, the PI's identity and funding information would generally remain publicly available.

I worry that researchers will become reluctant to report incidents if they believe doing so could result in a public report identifying their PI, research program, and grant funding.

Even when an incident is appropriately managed and does not involve negligence or serious noncompliance, public disclosure may create reputational concerns or perceived consequences for future funding.

These concerns may be particularly significant for graduate students, postdoctoral researchers, and other laboratory personnel who may hesitate to report an incident if they believe it could negatively affect their PI or laboratory.

From a biosafety perspective, this is exactly the opposite of the reporting culture we should be encouraging.

I am particularly troubled by the requirement to publicly post incident reports for lower-risk incidents that do not require reporting to NIH. If an institution has appropriately reviewed an incident, evaluated the potential hazards, and implemented corrective actions, I question what additional safety benefit is achieved by requiring the institution to publicly identify the investigator and research program involved.

I strongly support transparency, accountability, and sharing lessons learned from biosafety incidents. However, I do not believe that publicly identifying individual investigators and institutions is necessary to achieve those objectives.

I recommend that NIH establish a centralized, de-identified national biosafety incident reporting database instead of requiring institutions to publicly post individually identifiable incident reports.

Institutions could submit standardized incident reports to NIH, including information necessary for regulatory oversight and investigation. NIH could then make de-identified incident information publicly available through a searchable national database.

Such a database could include incident types, biological agents involved, contributing factors, root causes, containment failures, corrective actions, and lessons learned, while removing institutional names, investigator identities, and grant identifiers.

I believe this would be an incredibly valuable resource for the biosafety community. Biosafety professionals could review incidents from across the country, identify recurring problems, evaluate effective corrective actions, and use this information to improve their own institutional programs.

Currently, valuable lessons learned from laboratory incidents are often limited to the institutions where they occurred. A centralized national database could meaningfully improve the sharing of this information and help prevent similar incidents elsewhere.

More importantly, this approach would support transparency and collective learning without creating unnecessary disincentives for researchers to report incidents to their biosafety offices.

We should be creating policies that encourage researchers to report more incidents, not policies that may make them think twice before contacting Safety.

Expansion of IBC Oversight and the Definition of Genetic Modification

I support expanding biosafety oversight beyond recombinant and synthetic nucleic acid research when additional biological hazards warrant institutional review.

However, I am concerned that the proposed scope is overly broad and not consistently aligned with the subsequent categories of research requiring full IBC review.

The proposed definition of genetic modification includes stable alterations to the genome resulting from passaging, reassortment, chemical treatment, or radiological means.

These methods are used in a wide range of biomedical research activities, many of which have historically been considered routine laboratory research.

While some modifications may increase biological hazards, others do not meaningfully change the risk associated with the biological material.

Under the proposed framework, it appears that a significant amount of research involving these modifications could require full IBC review rather than delegated review, even when the research presents relatively low biological risk.

I am concerned that this is inconsistent with NIH's stated objective of reducing administrative burden for lower-risk research.

From a practical standpoint, expanding full committee review to encompass substantially more routine research will increase the workload for investigators, biosafety offices, and volunteer IBC members.

More importantly, it may divert attention and resources away from research presenting more significant biological hazards.

I encourage NIH to clarify the distinction between genetic modifications that create meaningful changes in biological risk and those that do not.

The level of IBC oversight should be based on the actual biological hazards associated with the research, rather than the method used to produce a genetic modification.

I also recommend that NIH clarify the relationship between the full committee and delegated review categories so that research specifically eligible for delegated review is not inadvertently captured by a broader full committee classification.

Administrative Burden and Three-Year Approval Periods

The proposed policy would substantially increase the amount of research requiring IBC registration and review. Investigators would need to provide more comprehensive descriptions of their biological research activities, and institutions would need to expand their registration and oversight systems.

I am concerned that this additional administrative burden will not necessarily translate into improved laboratory safety.

I am also concerned about the proposed requirement that IBC approvals not exceed three years, followed by de novo registration and review.

At my institution, IBC protocols are currently approved for five years, with amendments reviewed when research activities or biological hazards change.

Requiring a new submission every three years, even when the research has not materially changed, will increase the administrative workload for both investigators and IBCs.

I recognize the importance of periodic review, but I believe that oversight should be proportionate to risk.

For established, lower-risk research, I encourage NIH to consider longer approval periods or streamlined renewal procedures, while continuing to require review of significant changes that may affect the original risk assessment.

Biosafety professionals and IBC members have limited time and resources. I believe those resources are most effectively used evaluating new hazards, changes in research activities, and higher-risk experiments rather than repeatedly reviewing unchanged research solely to satisfy an administrative renewal requirement.

Public Meeting Minutes and Risk Assessment Information

I support transparency in IBC decision-making and recognize the public's interest in understanding how institutions oversee biological research.

However, I am concerned about the level of detail required in the proposed public meeting-minutes template, particularly the requirement to include detailed risk assessments and descriptions of experimental manipulations.

IBC members need access to comprehensive information to conduct meaningful risk assessments. However, I do not believe that all of this information necessarily needs to be included in publicly accessible meeting minutes.

Institutions should maintain detailed internal records documenting their risk assessments, discussions, and approval decisions. Public meeting minutes should demonstrate that appropriate oversight occurred without requiring unnecessary disclosure of detailed experimental information.

I encourage NIH to provide greater flexibility regarding the level of technical detail included in public meeting minutes and clearer guidance on appropriate redactions.

Implementation Timeline

Finally, I am concerned that the proposed six-month implementation period is insufficient given the magnitude of the changes.

Institutions will need to revise their biosafety policies, IBC procedures, protocol registration systems, review categories, incident-reporting practices, and public disclosure processes. Researchers and committee members will also need training on the new requirements.

I encourage NIH to consider a phased implementation period of at least 24 months and to provide comprehensive guidance, practical examples, and standardized resources to support the transition.

I also encourage NIH to consider issuing a revised draft for additional public comment, particularly to address the ambiguities surrounding the scope of covered research and the distinctions between full committee and delegated review.

Conclusion

I appreciate the NIH’s efforts to modernize biosafety oversight and recognize the importance of maintaining strong institutional biosafety programs.

However, I encourage NIH to consider how the proposed policy will function in practice and whether the additional requirements will meaningfully improve laboratory safety.

As a biosafety professional, I believe effective oversight requires more than comprehensive regulations and documentation. It requires relationships,

communication, trust, and the willingness of researchers to engage openly with institutional biosafety personnel.

My greatest concern is that the proposed public incident-reporting requirements could undermine those relationships and discourage researchers from reporting the very incidents that biosafety professionals need to know about.

I strongly support establishing a centralized, de-identified national biosafety incident database that would allow institutions to learn from incidents across the research community without publicly identifying individual investigators and institutions.

I also encourage NIH to ensure that the final policy is genuinely risk-based, provides appropriate opportunities for delegated review, and avoids imposing unnecessary administrative requirements on routine biological research.

Ultimately, I believe the success of this policy should be measured not by the volume of research registrations, committee reviews, or publicly posted reports, but by whether it helps institutions identify hazards, prevent incidents, and foster a research environment where safety concerns are openly communicated and effectively addressed.

Thank you for considering these comments.

Sincerely,

Jennifer Ramil, MBA, RBP (ABSA)

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Labs use long lists of human cells lines in their research. The proposed policy requires the registration of genetic modifications introduced into cells by passaging, reassortment, chemical or radiological means. The effort it would take to register every last cell line under this scope far outweighs any benefit this would have to oversight and safety. To understand and asses the nuanced differences between all these genetic variations would take a tremendous amount of time and education for biosafety professional and IBC members when the risk of any human cell line remains the same for one cell line to another. Performing a comprehensive risk assessment prior to initiating research involving these human cells, when this work has already been going on for decades but was never captured in an IBC registration, would also be a burden that far exceeds any benefit. What is the risk assessment of any human cell line beyond what is required under OSHA's BBP Standard? There are already mechanisms and guidance in place for working with this material and no further registration is required.

Sanford Burnham Prebys – Institutional Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

Sanford Burnham Prebys (SBP) appreciates the opportunity to provide comments on the Draft NIH Biosafety Policy for Research Involving Biohazards. We support NIH's efforts to modernize biosafety oversight, strengthen institutional accountability, and establish a more comprehensive, risk-based framework for the safe conduct of biomedical research.

SBP recognizes the importance of maintaining effective biosafety oversight as research technologies and biological hazards continue to evolve. We also appreciate NIH's stated goal of reducing unnecessary administrative burden for lower-risk research while focusing institutional oversight on activities presenting meaningful biosafety risks.

However, we are concerned that several provisions of the proposed policy may have unintended consequences, including substantially expanding IBC oversight of routine biological research, increasing administrative requirements for investigators and institutions, and potentially discouraging the reporting of laboratory incidents.

Our primary recommendations are outlined below.

Public Disclosure of Incident Reports and the Potential Impact on Institutional Safety Culture

SBP's most significant concern is the proposed requirement for institutions to publicly post biosafety incident reports, including incidents that are reported to NIH and lower-risk incidents that are reviewed by the IBC but do not require NIH reporting.

Effective institutional biosafety programs depend upon open communication, collaboration, and trust between researchers and biosafety professionals. Researchers must feel comfortable promptly reporting exposures, spills, containment failures, procedural errors, near misses, and other potential safety concerns. These reports allow institutional biosafety professionals and IBCs to provide immediate assistance, evaluate potential hazards, identify root causes, implement corrective actions, and prevent future incidents.

We are concerned that mandatory public disclosure of incident reports could fundamentally alter this relationship.

The proposed incident-reporting template requires identification of the Principal Investigator and associated NIH grant information. Although individual laboratory personnel should not be identified, the PI's identity and funding information would generally remain publicly available.

Public disclosure of this information may create reputational or funding concerns for investigators, even when incidents are promptly reported, appropriately managed, and do not result from negligence or significant noncompliance. Investigators may reasonably perceive that reporting an incident could negatively affect their professional reputation, future funding opportunities, or the public perception of their research programs.

More importantly, these concerns could discourage researchers from voluntarily reporting incidents to institutional biosafety offices. We believe this represents a potentially serious unintended consequence of the proposed policy.

A strong safety culture encourages researchers to report concerns early, including incidents that may initially appear minor or for which the actual risk is uncertain. Institutional biosafety programs rely on these communications to identify emerging hazards and prevent more serious incidents. If researchers become concerned that contacting their biosafety office could ultimately result in a publicly posted incident report identifying their PI and grant information, they may become less willing to report events.

We are particularly concerned about the requirement to publicly post reports for lower-risk incidents that do not meet NIH reporting thresholds. Requiring public disclosure of these incidents may discourage reporting without providing a corresponding improvement in biosafety oversight.

Recommendation:

SBP strongly recommends that NIH reconsider the requirement for institutions to publicly post individually identifiable incident reports, particularly those involving lower-risk incidents that do not require NIH reporting.

Instead, we recommend that NIH establish a **centralized, de-identified national biosafety incident reporting database.**

Under this approach, institutions would submit standardized incident information to NIH, and NIH would maintain a publicly accessible database that removes institutional names, investigator identities, personnel identifiers, and grant information.

The database could include information such as:

- Biological agents and research activities involved;
- Types of incidents and potential exposures;
- Contributing factors and root causes;
- Containment failures or equipment issues;
- Corrective and preventative actions; and
- Lessons learned and recommendations for preventing similar incidents.

We believe this approach would provide significantly greater value to the biosafety community than requiring individual institutions to post incident reports on their respective websites.

A centralized national database would allow biosafety professionals, IBCs, researchers, and NIH to identify recurring incident types, emerging hazards, common contributing factors, and effective corrective actions across institutions. Such a response could directly inform institutional training, risk assessments, standard operating procedures, and prevention strategies.

Importantly, this approach would promote transparency and shared learning while preserving the collaborative relationship between researchers and institutional biosafety professionals.

We encourage the NIH to prioritize a reporting framework that supports learning and prevention rather than one that may inadvertently discourage incident reporting.

Expanded Scope of the Policy and Consistency with Risk-Based Oversight

SBP supports expanding biosafety oversight to address biological hazards that may not be adequately covered by the current NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules.

However, we are concerned that the proposed policy's broad scope is not consistently reflected in its subsequent review and oversight requirements.

In particular, the proposed definition of genetic modification includes stable alterations to the genome resulting from passaging, reassortment, chemical treatment, or radiological means.

These techniques are used in a wide variety of biomedical research activities, including routine cell culture, experimental selection, and the development of research models. While certain modifications may increase biological hazards and warrant additional oversight, not all such modifications result in an increased biosafety risk.

When this broad definition is considered alongside the proposed categories requiring full IBC review, it appears that a substantial amount of routine biological research could become subject to full committee review rather than delegated review.

This outcome would appear inconsistent with NIH's stated objective of reducing unnecessary administrative burden for low-risk research.

We are concerned that requiring full committee review based primarily on the method of genetic modification, rather than the resulting biological hazard, could divert limited IBC resources away from research presenting more significant risks.

Recommendation:

We recommend that NIH clarify the relationship between the definition of genetic modification and the categories of research eligible for full committee or delegated review.

Specifically, NIH should establish clear criteria distinguishing modifications that introduce or increase a meaningful biological hazard from modifications that do not materially change the risk profile of the organism or research activity.

Research involving genetic modifications that do not increase pathogenicity, transmissibility, host range, environmental persistence, toxicity, or other relevant biological hazards should be eligible for delegated review or another proportionate oversight pathway.

We also recommend that NIH provide additional examples and decision-making guidance to assist institutions in consistently assigning research to the appropriate review category.

The level of IBC oversight should be determined by the potential biological risk of the proposed research rather than the technique used to generate a biological modification.

Increased Administrative Burden and Protocol Approval Duration

The proposed policy would substantially increase administrative responsibilities for investigators, institutional biosafety offices, and IBC members.

By expanding the scope of covered research, institutions may need to register and review a significantly larger proportion of their biological research activities.

Principal Investigators would be required to provide more comprehensive information about their research activities, biological materials, experimental manipulations, and associated risk assessments. Institutions may also need to substantially restructure their existing IBC registration systems to ensure that all covered activities are appropriately documented and reviewed.

Additionally, the proposed policy limits IBC approval periods to no more than three years and requires de novo registration and review at the end of the approval period.

SBP currently maintains a five-year IBC protocol approval cycle, with additional oversight of higher-risk research and review of amendments as appropriate.

Requiring de novo review every three years would increase the frequency of protocol submissions, administrative processing, and committee review, including for established research activities that have not materially changed and do not present increased biosafety risks.

We recognize the importance of periodic review and ensuring that approved research remains consistent with current biosafety practices. However, we question whether requiring a new review of otherwise unchanged, lower-risk research every three years provides a corresponding improvement to biosafety.

Recommendation:

We recommend that NIH allow institutions greater flexibility in establishing protocol approval periods based on the risk associated with the research.

For lower-risk research, NIH should consider permitting longer approval periods, streamlined renewals, or delegated review of continuing research that has not materially changed.

Institutions should retain responsibility for reviewing significant amendments, changes in biological hazards, containment requirements, or experimental procedures that could affect the original risk assessment.

We believe this approach would preserve appropriate oversight while allowing investigators and IBCs to focus their resources on research presenting meaningful biosafety risks.

Public Meeting Minutes and Disclosure of Research Risk Assessments

SBP recognizes the importance of transparency in institutional biosafety oversight and supports making appropriate information about IBC activities available to the public.

However, we are concerned that the proposed meeting-minutes template requires extensive details regarding individual research protocols, biological agents, experimental manipulations, and associated risk assessments to be included in publicly accessible meeting minutes.

These requirements could result in public disclosure of detailed research information that may be scientifically sensitive, preliminary, or potentially subject to misinterpretation without appropriate context.

We recognize that the draft policy allows redaction of certain protected information. However, the proposed limitations on redaction may not adequately address the concerns associated with publishing detailed experimental risk assessments.

We are also concerned that requiring extensive protocol-specific information in public meeting minutes may increase administrative workload and shift committee attention toward documentation requirements rather than substantive evaluation of biosafety risks.

Recommendation:

We recommend that NIH distinguish between the detailed documentation necessary for effective IBC review and the level of information necessary to demonstrate appropriate institutional oversight to the public.

Institutions should maintain comprehensive internal records documenting risk assessments, committee discussions, and approval decisions.

Public meeting minutes should provide sufficient information to demonstrate that the IBC evaluated the relevant hazards, establishing appropriate containment measures, and made an informed approval decision, without requiring disclosure of unnecessary experimental details.

NIH should also provide clearer guidance regarding the appropriate redaction of sensitive research information and allow institutions reasonable discretion to protect legitimate research confidentiality and security interests.

Implementation Timeline and Institutional Resources

The proposed policy represents a substantial change to the current NIH biosafety oversight framework.

Implementation will require institutions to evaluate and revise existing biosafety policies, IBC procedures, protocol registration systems, review classifications, reporting processes, training programs, and public disclosure practices.

Institutions may also need to increase administrative support and committee resources to accommodate the expanded scope of research requiring IBC review.

We are concerned that the proposed six-month implementation period may not provide sufficient time for institutions to make these changes effectively, particularly if NIH does not release detailed implementation guidance and standardized resources until after the policy is finalized.

Recommendation:

We recommend the NIH consider a phased implementation period of at least 24 months, accompanied by clear guidance, standardized templates, and practical examples demonstrating how the new policy should be applied.

We also encourage NIH to consider publishing a revised draft for additional public comment after addressing the questions and ambiguities identified by institutions and professional biosafety organizations.

A longer implementation period would allow institutions to establish consistent oversight processes, provide appropriate training to investigators and committee members, and transition existing research registrations without unnecessary disruption to ongoing research.

Conclusion

SBP supports NIH's efforts to modernize biosafety oversight and establish a more comprehensive, consistent, and risk-based approach to managing biological hazards in biomedical research.

However, we encourage NIH to carefully consider the potential unintended consequence of the proposed policy, particularly the substantial expansion of IBC oversight, the increased administrative burden associated with routine research activities, and the effects of mandatory public incident disclosure on institutional safety culture.

Of these concerns, we believe the proposed public incident-reporting requirements warrant particular reconsideration.

Effective biosafety programs depend on researchers being willing to report incidents, ask questions, and seek assistance from institutional biosafety professionals. Policies that inadvertently discourage these interactions may undermine the very safety objectives they are intended to advance.

We strongly encourage NIH to establish a centralized, de-identified national biosafety incident reporting system that promotes transparency, shared learning, and prevention while protecting the collaborative reporting culture essential to effective institutional biosafety oversight.

We further recommend that NIH clarify the scope of covered research, ensure that oversight requirements remain proportionate to actual biological risks, provide greater flexibility for lower-risk research, and allow institutions adequate time to implement the new framework.

We appreciate NIH's consideration of these comments and its continued engagement with the biosafety community.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): IBC

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft states that it covers all biomedical research in laboratory settings involving biohazards, but it does not define "biohazard" as a standalone term. Instead, the operative scope combines a human-health risk threshold with specified categories of biological materials. This creates uncertainty regarding materials that may principally affect animals, plants, agriculture, or the environment and creates tension with provisions requiring IBCs to assess environmental and population-level effects. NIH should define "biohazard" and clearly state whether risks to animal health, plant health, agriculture, and the environment are within scope, outside scope, or addressed through another federal framework. The final policy should also include a comprehensive glossary defining terminology that determines policy applicability, oversight requirements, and reporting obligations.

The exclusion of genetically modified plants and plant pathogens that do not cause human disease may reduce duplicative oversight, but the draft continues to assign IBC responsibilities for environmental risk and references animal and plant health requirements in other contexts. NIH should explicitly address contained greenhouse work, plant-associated microorganisms, genetically modified plant pathogens, animal-only pathogens, and research involving agricultural animals. The final policy should also explain when oversight by USDA or another federal agency satisfies NIH policy requirements and when concurrent NIH or institutional oversight remains necessary.

The final policy should also clarify the organizational boundaries of an "institution" when applying the policy to non-NIH-funded research. This is particularly important for institutions operating across multiple campuses, affiliated hospitals, separately incorporated entities, shared research environments, external research sites, or shared IBC arrangements. Responsibility should also be clearly defined when more than one institution conducts, sponsors, or provides oversight for covered research.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): To better calibrate oversight to risk, commercial transgenic animals maintained at ABSL-1, low-risk plasmids, replication-

incompetent non-integrating vectors expressing low-risk transgenes, well-characterized cell lines, and genetically modified RG1 organisms should be eligible for administrative review or exemption, as appropriate based on risk, rather than automatically requiring full IBC member review. Institutions should be permitted to use a documented screening process to determine whether the work presents minimal biosafety risk. NIH should establish an administrative registration pathway while allowing institutions to elevate individual registrations for IBC review when local circumstances or the institutional risk assessment warrant.

NIH should also create a searchable national repository of NIH containment determinations and risk classifications and define substantial equivalence, permissible deviations, documentation expectations, and responsibility for determining whether a prior determination applies. Where the policy permits publication of approved lower-containment determinations, NIH should clarify whether and under what conditions another institution may rely upon an existing determination.

3. Continued utility of Risk Groups: A universal minimum of BSL-2 for GDMOs does not readily map to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. NIH should allow risk-based equivalent containment approaches and provide technology- and system-specific guidance.

NIH should also clarify the role of Risk Group classifications in determining oversight. Risk Group should inform, but not substitute for, an experiment-specific risk assessment. Risk Group classifications should not be treated as equivalent to a required Biosafety Level, IBC review category, or containment determination. Oversight and containment decisions should consider the biological material, experimental procedures, quantity and concentration, routes of exposure, host characteristics, engineering controls, and potential consequences of release.

Influenza provisions should also specify which gene segments, combinations or proportions of genetic material, phenotypic characteristics, and virus types trigger enhanced BSL-3 containment, rather than using language that could be interpreted to apply broadly to constructs containing any listed influenza segment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The draft states that research also under another federal agency's regulation or purview "may proceed under the oversight of the other federal agency" once applicable approvals or clearances have been obtained. Elsewhere, however, the policy contemplates institutional and regulatory approvals operating concurrently. The final policy should clearly distinguish circumstances in which another federal agency's oversight substitutes for NIH federal review from those in which institutional requirements, including IBC review, biosafety oversight, and incident reporting, remain applicable.

NIH should also clarify the qualifications, authority, and institutional support expected for the Biological Safety Officer or other official assigned these responsibilities. These expectations should be commensurate with the institution's research portfolio and risk profile rather than based solely on the presence of BSL-3, BSL-4, or gene drive research.

Institutions should retain flexibility to determine appropriate qualifications based on education, training,

experience, and demonstrated biosafety competency. Professional credentials, such as the Registered Biosafety Professional and Certified Biological Safety Professional, may provide evidence of competency but should not be established as mandatory qualifications. NIH should also recognize that effective implementation will require adequate institutional authority, staffing, resources, access to relevant research spaces and records, and the ability to elevate unresolved risks to institutional leadership.

Mandatory public posting of detailed IBC minutes and incident reports raises legitimate concerns regarding proprietary research information, personal privacy, research security, biosecurity, and the potential identification of individual researchers. Although the draft recognizes certain allowable redactions, additional standards are needed to ensure consistent application across institutions and to avoid disclosure of information that could create security or biosecurity risks.
Public reporting requirements should also be structured so they do not inadvertently discourage prompt reporting of minor incidents and near misses, which are important components of a strong safety culture. NIH should consider requiring standardized, de-identified public summaries focused on oversight outcomes, corrective actions, and lessons learned, while maintaining detailed records for NIH oversight and other legally required disclosure processes.

NIH should also clarify how public-disclosure requirements are to be reconciled with applicable CDC and USDA biosecurity requirements, particularly for research involving select agents and toxins. The final policy should establish minimum mandatory redaction standards for security-sensitive information, including information that could identify personnel, reveal sensitive facility characteristics, compromise proprietary research, or create personnel or institutional security risks.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft should define “incident,” “release,” “loss of containment,” “basic first aid,” “agent-specific treatment,” “potential exposure,” “compliance violation,” and “minor spill.” The policy should specifically clarify whether precautionary post-exposure prophylaxis constitutes “agent-specific treatment” for reporting purposes.

NIH should also clarify whether any event occurring in a BSL-3 or BSL-4 laboratory is reportable regardless of its relationship to biohazard containment or exposure potential. The policy should distinguish administrative or procedural noncompliance from events presenting an actual or potential biosafety risk.

The reporting framework should be tiered according to risk and consequence. Events involving significant exposure, escape of biological material beyond defined containment boundaries, loss of containment, potential community impact, or other serious biosafety consequences may warrant rapid notification. A facility or equipment failure should not, by itself, be considered a release when functioning redundant systems maintain containment and prevent personnel exposure or environmental release. Administrative noncompliance and lower-risk events should not necessarily require the same reporting timeframe as consequential events.

NIH should consider allowing up to 72 hours for initial reporting of events that do not present an immediate or significant biosafety risk, while retaining a shorter notification requirement for serious events. This would allow institutions sufficient time to gather relevant facts, consult with occupational

health and other involved parties, assess potential exposures, and provide NIH with more accurate and meaningful initial information.

6. Other feedback relevant to this resource: The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, identify the organizational boundaries of covered activities, obtain an approved Biosafety Assurance, revise institutional policies, redesign electronic systems, establish public-facing processes and redaction standards, revise incident-reporting workflows, train affected research communities, secure institutional approvals and resources, or, in some cases, establish an entirely new IBC or biosafety program.

NIH should provide at least 24 months from publication of the final policy and associated implementation materials, with phased implementation milestones and transitional or provisional assurance mechanisms that prevent unnecessary interruption of ongoing research.

NIH should also publish comprehensive implementation guidance, model procedures, standardized templates, decision tools, and examples that institutions can adapt locally. These materials should address scope determinations, institutional boundaries, risk-based review pathways, coordination with other federal agencies, BSO responsibilities, incident classifications, reporting thresholds, public disclosure, and redaction standards.

The implementation materials should be available sufficiently in advance of the effective date to allow institutions to develop, validate, and implement compliant systems and processes. The implementation period should not begin until the final policy and the materials necessary to operationalize it have been issued.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Draft focused heavily on rDNA, as stated many times already. There's a ton of other biosafety topics that can be discussed. I think maybe having 5 – 10 of the top topics listed and broken down from there, there is just too much to consider in the biosafety world. Obviously need to stay focused on what affects us here and not delve into topics that aren't relevant. I'm sure this will come following comments. Maybe a tiered approach would work, break topics into groups and have a specialist in those areas talk on..??

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): How does this affect our team of 2 at our institution. Again, clarity and actual deliverables are needed. Considering the true scope of our objectives is something we need to stay focused on.

3. Continued utility of Risk Groups: This makes things confusing, I've used them interchangeably in the past but tend to use BSL over RG in trainings. It would be helpful if the NIH would clearly point out the key difference and indicate where/when to use RG vs BSL. At our level we give students the important, relevant info needed to get them started. Are PI's following up at all to add to what we're providing?

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I think voluntary compliance is a good idea and how change needs to begin, but the NIH should be more involved and set deadlines with clear objectives and expectations. We need to be well informed, and info should be readily available and easy to understand. Following implementation, a 6 month and annual follow-up should be required. During the implementation period NIH should be available to answer questions. Clarity, deadlines, guidance, and follow-up.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The templates are good for guidance, but every org. is different and may have different info to include based on their research. Given the publication of this information and the group of individuals it reaches, it should be easy to understand.

6. Other feedback relevant to this resource: Needs to be straight forward in expectations of NIH and labs with clear directives. This is especially true for the biosafety team. I also think it would be helpful to have resources allocated and discussed.

I think change is good, but this change needs to be well documented with guidance. Over time (hopefully ~ 6 months) I think this will be ironed out and maybe the draft was meant to foster conversation on a high level and we'll get into the weeds over time.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: NIH should exempt from the NIH Biosafety Policy all Contract Research Organizations (CROs) and Contract Development and Manufacturing Organizations (CDMOs) that work with client materials and products that fall under the scope of the NIH Biosafety Policy and that were developed by the client with NIH funding. The exemption should not include clinical research as noted in Section IV-2 of the Draft NIH Biosafety Policy whereby such materials and products are administered to human research subjects. CROs perform clinical/commercial quality control testing in a laboratory setting and CDMOs perform scale up and production on behalf of clients. The client, not the CRO or CDMO, should be responsible for compliance with the NIH Biosafety Policy. CROs and CDMOs should be encouraged to adopt the NIH Biosafety Policy as best practice.

NIH should define and limit the breadth of compliance scope as it pertains to large international biopharmaceutical companies where not all sites receive NIH funding for research with biohazards covered under the NIH Biosafety Policy. The NIH Biosafety Policy scope should be limited to only those company sites that perform NIH-funded research. For example, if a biopharmaceutical company has one location at a subsidiary in the United States that receives NIH funding for research with biohazards, only that site should be subject to the NIH Biosafety Policy. The entire subsidiary and potentially the entire company (including non-US sites) should not be in scope for compliance but should be encouraged to adopt the NIH Biosafety Policy as best practice.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: NIH should remove the requirement to publicly identify the PI and the biohazardous material involved in an incident. Identification of the PI in the public domain may have negative consequences such as failure of the PI to report incidents, potentially decreasing the safety culture of the institution. If the PI name is publicly available there is a potential security threat to the institution and the PI, should animal rights activists and others use that information to target the PI and/or the institution. OSHA, for example, does not require the names in required annual posting of the OSHA 300 Log in a workplace. Additionally, in private industry, a full description of the "nature of biohazardous material involved in incident" may expose confidential information that a company may not want to publicly disclose to protect intellectual property.

RE: Comments for the Draft NIH Biosafety Policy for Research Involving Biohazards (Request for Comment – NOT-OD-26-112, dated August 19, 2026)

To whom it may concern,

I am an infectious disease immunologist in the Department of Microbiology and Immunology, as well as a member of the Institutional Biosafety Committee, with the University of Texas Medical Branch in Galveston, Texas. My comments regarding the Draft NIH Biosafety Policy for Research Involving Biohazards (the Policy) (NOT-OD-26-112, dated August 19, 2026) are below.

I support the replacement of the *NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules* (*NIH Guidelines*) with risk-based biosafety oversight. I offer these comments to help NIH develop clear, proportionate, and workable requirements that protect personnel, the public, agriculture, and the environment, while enabling responsible scientific research.

The significant concerns in these comments and raised by the broader scientific community demonstrate that the draft Policy cannot be implemented in its current form. We respectfully request that NIH revise the Policy and publish additional drafts for public comment before final issuance. While we fully support NIH's objective of modernizing biosafety oversight through a risk-based approach, implementing a poorly defined policy will hamper biomedical research, create widespread administrative confusion, lead to unintentional noncompliance, and damage the collaborative relationship among researchers, regulators, and the biosafety compliance community.

1. **Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.**
    a. The stated intention of this policy proposal is to expand the scope of the *NIH Guidelines* while removing red tape for low-risk research. The goal of removing red tape for low-risk research within this Policy has not succeeded. The Draft Policy includes within its scope multiple categories of research that are currently Exempt in the *NIH Guidelines*. For example, research with certain transgenic rodents and certain recombinant work with non-pathogenic *E. coli*; the NIH Director has already determined that these experiments are of such low risk that they were actively designated as Exempt, yet this Policy considers them of high enough risk to require IBC approval. The Policy does not provide reasoning for this change in the risk assessment.
    b. A meaningful administrative burden with the *NIH Guidelines* is the pathway through which NIH OSP will assign a biocontainment level for research with an agent that does not have an assigned RG within Appendix B. This issue could be less burdensome if NIH OSP had been granted authority within the *Guidelines* to assign a risk group to agents that do not have risk groups.
        i. The current approval pathway is limited to the specific PI at a specific entity. Therefore, other PIs at the same entity are similarly required to obtain a biocontainment level from NIH OSP for the same agent.
        ii. **We recommend** that the Policy clearly state that determinations of risk group and/or recommended biosafety levels will apply to all researchers and all entities subject to the Policy.
            1. We understand that there will be differences in the recommended biosafety level due to geography/climate and considerations for research being performed outside the US, which should be considered if this recommended change is made to the Policy.
    c. The Scope of the Policy states “Any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained.”
        i. This statement must be clarified. We appreciate that the Policy seeks to avoid duplicative oversight from multiple federal agencies. However, the statement itself is unclear regarding the oversight, approvals, and clearances that are mentioned.
            1. If a researcher is registered to work with wildtype Nipah virus (RG4, therefore falling under Section IV-2) with the Federal Select Agent Program (FSAP), do they not need to obtain IBC approval for the same work?

2. If a researcher is registered to generate chimeras of paramyxoviruses within a Nipah virus backbone (a novel agent by the current definition, therefore falling under Section IV-1) with FSAP, do they need to obtain NIH and IBC approval for the same work?
3. If an incident occurs in a BSL3 or BSL4 that involves a Select Agent for which the researcher is registered with FSAP, does the incident get reported to NIH and posted on a public facing website?

d. Effective Date
   i. The Policy states that the effective date will be 6 months from publication of the final Policy. This is a very short timeline to implement a Policy with such significant expansions in scope. Implementation of this Policy will require that IBCs ask for more resources from their institutions, obtain those resources, communicate with stakeholders, develop new training, implement training for IBC members and researchers, obtain new software or update software, and make significant choices in how to implement each part of the Policy. Six months is not nearly sufficient, and all entities will struggle.
   ii. This is further complicated by the need to provide a written Biosafety Assurance that has been approved by NIH in order to perform any research after the effective date. Will NIH have the required full-time employees (FTEs) to review and approve hundreds of Biosafety Assurances that will be submitted within that effective date?
   iii. **We recommend** that the effective date be at least 2 years.
e. The Policy uses terms and words but does not define them. The failure to define these words will lead to ambiguity in the interpretation and implementation of the Policy, leading to unintentional noncompliance. Further, some of these words did not have definitions in the *NIH Guidelines* and therefore this is a good opportunity to rectify this issue. These include:
   i. Adventitious agent, organism, transgenic, GDMO, incident, release, potential risk to human health, peptide, shedding
      1. Organism is inconsistently used within the Policy and is not an easily defined word. Replace “organism” with more appropriate and easily definable terms throughout the Policy. Specify bacteria, fungi, archaea, protists, viruses, or animals as needed. If there is a concern about a biological agent that doesn’t fall within those terms, be clear about that (e.g., a biological agent created through synthetic biology that cannot be readily categorized).
f. The Policy omits a review workflow for biological agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL yet cannot reasonably fall within the definition of “emerging, novel, or

zoonotic agents". This is a crippling issue for agents that are currently handled at BSL1 or BSL2, though is also an issue for agents handled at BSL3 and BSL4.

i. Theoretically, these could fall within Section IV-1 (research that requires NIH and IBC approval before initiation). However, the administrative burden on NIH to adequately review this work in a timely manner would be significant (even ignoring the administrative burden on researchers and IBCs to review this work). Additionally, much of this research cannot reasonably fall under the category of "higher risk research", when even research involving RG3 or RG4 wild-type biological agents requires only IBC review in the Policy.
ii. For example, human metapneumovirus, non-polio enteroviruses, human parainfluenza virus 5 (Orthorubulavirus mammalis), and Sendai virus (Respirovirus muris) are not emerging, novel, or zoonotic agents. Yet they lack a risk group in the *NIH Guidelines* and are not mentioned in the BMBL. Will NIH review be required for research with these agents for every entity and researcher that falls in scope of the Policy? If so, how many FTEs will NIH be hiring to accomplish timely reviews?
iii. How will human or animal microbiota be treated in this review workflow? Will research with every member of *Bacteroides*, *Bifidobacterium*, *Akkermansia*, *Ruminococcus*, *Prevotella*, and *Anaerococcus* require NIH review? If so, will a researcher even be able to collect a human or animal sample without being in noncompliance with the Policy?

g. The Policy does not define who has the authority to designate the risk group of an agent.
   i. This is of particular importance with RG1 biological agents, since the Policy explicitly states that wild-type RG1 biological agents are outside the scope of the Policy.
   ii. If the local IBC will have the authority to designate the risk group of an agent, that needs to be stated in the Policy.
   iii. If the NIH will have the authority to designate the risk group of an agent, that needs to be stated in the Policy. In addition, NIH must publish and regularly update the list of biological agents that it designates at different RGs.
h. **Responsibilities of the Institution (Section III-A), related to records retention**
   i. The Policy states "The institution must maintain all IBC records in accordance with Section 8.4.2 of the NIH GPS, which requires recipients of awards to maintain appropriate documentation in accordance with record retention requirements in 2 CFR 200.334, which states "the recipient and subrecipient must retain all Federal award records for <u>three years from the date of submission of their final financial report</u>." (emphasis added).
   ii. The Policy assumes that all IBC records are for projects that are federally funded. The Policy has failed to consider projects that are not federally funded

and therefore will never submit a final financial report. As written, such IBC records may never be disposed of, which is either an oversight or regulatory overreach. **This language must be changed to account for IBC records related to non-federally funded projects.**

i. **Responsibilities of the IBC (Section III-B), related to approval period**
    i. The Policy states “Approval should be granted for a period not to exceed three years, at which time a *de novo* registration submission and review is required.”
        1. The Policy fails to describe how biosafety or biosecurity is increased by limiting research approvals to three years. Researchers continue projects over years and decades, and these projects rarely include changes that significantly increase the risk assessment.
        2. Requiring a specific time frame for approvals is overly burdensome and regulatory overreach. Requiring such a short approval time will greatly increase the administrative burden of the IBC and the researcher for little to no increase in biosafety.
        3. **We recommend that this statement be removed from the Policy.**
        4. If the statement cannot be removed from the Policy, we recommend that the Policy explicitly permit grandfathering of previously approved IBC protocols that have approval periods of greater than three years.

j. **Responsibilities of the IBC (Section III-B), incident reporting**
    i. The Policy does not define “incident” or “release”. We recommend the following definitions:
        1. **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.
        2. **Release (Loss of containment or occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
    ii. The Policy does not define “improper disposition” and throughout this section relies on ambiguous phrases such as “any incident”, “loss of containment”, “significant problems”, and “minor spills … generally do not need to be reported”. Terms like “first aid” and “medical treatment” should be aligned explicitly with OSHA standards.

k. **Responsibilities of the NIH (Section III-D)**
    i. The Policy does not state which person or office within NIH will be responsible for these items. In comparison, the *NIH Guidelines* clearly delineated the responsibilities of the NIH Director and the responsibilities of the NIH Office of Science Policy.

1. Entities can reasonably expect that the response times for the NIH Director and for NIH OSP will be significantly different. Further, NIH OSP is staffed with many subject matter experts, while the NIH Director can never be an SME for every aspect of biomedical science. Therefore, the Policy must clearly state who will be responsible for these duties.
2. **We recommend that the Policy clearly state which person or office is responsible for the duties described in this section.**

2. **Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).**
    a. In general, the tiered oversight is appreciated. The IACUC-style review that specifically permits delegate approval will be a helpful decrease to time commitments from the full IBC for review of lower risk research.
        i. The Policy has replaced two previous categories of review, those requiring NIH Director approval (III-A) and those requiring NIH OSP approval (III-B), with a singular category that requires NIH approval. The Policy does not describe which person or office within NIH will be performing the review and approval of research within Section IV-1. This must be clearly stated in the Policy within the Responsibilities of NIH (III-D).
    b. **General Definitions: *Emerging agent or organism***
        i. The Policy does not state who determines that an agent is an emerging agent. Does the local IBC decide what qualifies as an emerging agent? If not the local IBC, we recommend that NIH develop rapid dissemination notices that are sent to all entities identify emerging agents so that entities can avoid noncompliance.
        ii. The Policy does not describe how an agent or organism goes from being an emerging agent to a non-emerging agent. Will an agent be "emerging" until the first time NIH has reviewed it under Section IV-1? Until it has been assigned a risk group? Until it has appeared in the next edition of the BMBL?
        iii. Does the definition of an emerging agent include a well characterized agent that exhibits a change in pathogenicity or transmission? If this Policy existed at the time, would the recent outbreaks of Zika virus, mpox virus, and Andes virus qualify as "emerging"? Would the label of emerging apply to the agent, or merely to the specific strain of the biological agent?
        iv. If considered now (October 2026), which agents would qualify as "emerging"? Highly pathogenic avian influenza virus H5N1? SARS-CoV-2?
    c. **General Definitions: *Genetic Modification***
        i. This definition is so expansive that it causes internal contradictions within the Policy.
        ii. The definition uses the undefined word "organisms", which is unhelpful. As written, this causes the Policy to confusingly regulate research conducted with <u>genetically modified</u> organisms (Section IV-2) differently from <u>transgenic</u> organisms (Section IV-3) but does not define the difference between the two. We recommend replacing the word organism with the biological agent(s) that are intended to be within scope of the Policy.
        iii. *Can be transcribed or translated:* as written, this will include expression from an RNA vaccine that is administered to an animal or transfected into a cell line. The Policy does not describe how including this as a genetic modification addresses a biosafety concern.

iv. *The introduction … of stable alterations into the genome by passaging, reassortment, chemical or radiological means:* as written, the definition includes unintentional alterations into the genome, such that researchers will become noncompliant with the Policy almost immediately.
    1. Passaging any virus in tissue culture will result in unintentional alterations into the genome.
    2. Cancer research includes work with antineoplastic drugs that would fall within scope of this definition.
    3. **We recommend that this definition be re-written to be limited to intentional stable modifications.**

d. **General Definitions: *Toxin***
    i. The definition of toxin could be greatly improved.
    ii. For example, ISO35001 uses "substance, produced by plants, animals, protists, fungi, bacteria, or viruses, which in small or moderate amounts produces an adverse effect in humans, animals, or plants. This includes substances and materials, natural or as a result of biotechnology, that may contain toxins, any poisonous substance or any poisonous isomer, homologue, or derivative of such a substance."
        1. The definition should not include proteins or peptides whose primary adverse effect results from allergic or hypersensitivity responses (e.g., sensitizers).
        2. Later in the Policy, when defining the Category of research, would be the appropriate time to limit the scope of which toxins fall under the Policy (e.g., Research with protein or peptide toxins not on the Select Agent list and with an LD50 of less than 100 micrograms per kg body weight.)

e. **Section IV-1 (Research that Requires NIH and IBC Approval Before Initiation): *Research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL.***
    i. Emerging and zoonotic agents:
        1. For those whose research focuses on the identification of new biological agents, the Policy offers no regulatory path to work with these agents. Once identified as an emerging or zoonotic agent with no risk group or biosafety level recommended in the BMBL, the research must be approved by NIH. However, without the ability to work with the agent, the researcher cannot generate the data required for NIH to conduct the risk assessment.
        2. Without the ability to perform this research, US researchers will stop performing this work. It will then fall to international researchers to spearhead this work, leaving US researchers lagging behind.

3. **We recommend** that a clear approval pathway is described in the Policy to allow researchers to generate the data required for a risk assessment. This would best be performed by the local IBC.

ii. Novel agents:
   1. The definition of novel agents includes chimeras. Many researchers generate chimeras (especially within a family of viruses) to study the basic biology of these agents; in these cases, the representative family member or the parental agents often already have risk groups assigned or biosafety levels recommended. Research with such biological agents does not qualify as "higher risk research" requiring NIH approval; indeed, these experiments currently fall within Section III-D of the *NIH Guidelines*, clearly demonstrating that for decades NIH has determined that the work can be reviewed by the local IBC and does not require NIH approval.
   2. **We recommend** that research involving chimeric agents generated within the same family (for viruses) or the same genus (for bacteria or fungi), may be reviewed by the IBC.
   3. **We recommend** that research involving chimeric agents where the natural sources have risk groups assigned and/or biosafety levels recommended, may be reviewed by the IBC.

f. **Section IV-2 (Research That Requires IBC Review and Approval Before Initiation)**
   i. This section states "For initial submissions of research within the scope of the policy, and not otherwise specified in other sections, review and approval must be obtained from the IBC before initiation."
   ii. Since the Policy includes a regulatory catch-all ("not otherwise specified in other sections"), the Policy must include a section that clearly delineates research that is outside the scope of the Policy. Institutions cannot rely on one-off notes to define research that is outside the scope (e.g., "[Note: Experiments involving RG1 wild-type biological agents are not subject to this Policy]"). Without clear delineation, entities will vary widely between unintentional noncompliance and overly requiring IBC review and approval for work that is outside the scope of the policy.

g. **Section IV-2: *Research involving RG3 or RG4 wild-type biological agents.***
   i. We have no objection to including RG3 and RG4 biological agents within scope of the Policy, as our institution already requires that work with these agents be approved by the local IBC.

h. **Section IV-2: *Research involving genetically modified cells, viruses, or organisms, other than plants (e.g., certain vectors, replicons, gene drive modified biological agents, GDMOs).***

i. Policy must be well written and clear; this category is a clear example of policy that is not well written. It is misplaced within the tiers of review; contains terms that are either not defined or badly defined; and conflicts with other categories of research within the Policy. Entities will be uncertain how to comply with this category, leading to chilling effects on the research community, additional administrative burden, and unintentional failures to comply with the Policy.
ii. This category is misplaced within the tiers of review. Research with genetically modified cells should be at most within Section IV-3 (delegate review), if not Exempted completely.
    1. The *NIH Guidelines* has included an exemption for recombinant DNA molecules containing less than one-half of any eukaryotic viral genome that are propagated and maintained in tissue culture at least since the Federal Register Notice in 1994 (Effective June 24, 1994, Published in Federal Register, July 5, 1994 (59 FR 34472)). The NIH Director has therefore determined that such experiments do not present a significant risk to health or the environment. The Policy does not describe how the inclusion of such research in the Policy will increase biosafety and biosecurity. In addition, while a single researcher registering for this work would not be a significant burden, the total number of registrations will constitute a significant collective administrative burden on the IBC and researchers that is not commensurate with the very low biosafety risk.
    2. Genetic modification of cells is of very low biosafety risk (barring some introduction of nucleic acids from certain biological agents, like RG3 or RG4 agents, or that will generate toxins). Such work should be exempt from the Policy.
iii. Genetic modification is defined by the Policy, but in such an expansive way that it is prohibitive to research.
    1. As an example: as written, the Policy no longer considers administration of recombinant nucleic acids (e.g., RNA vaccines) in humans to be within scope, compared to the *NIH Guidelines*, where it is within scope (Section III-C-1). However, the Policy includes “genetic modification” of cells and organisms, which as defined includes introduction of nucleic acid molecules that can be transcribed or translated (e.g., RNA vaccines). The Policy does not describe how it has conducted a risk assessment in which deliberate administration of an RNA vaccine into a human is not within scope, yet transfection of the RNA vaccine into cell culture or administration into an animal is within scope and requires IBC approval.
iv. Organism is not defined by the Policy, which makes this category frustrating to understand and will lead to significant unintentional noncompliance.

1. As written, this category appears to include animals, despite the category of “transgenic organisms at BSL1/ABSL1” listed in Section IV-3.
2. The word organisms must be defined by the policy or replaced in this section.

v. Vector is not defined by the Policy, which will lead to significant unintentional noncompliance. Is the intention here to regulate viral vectors (e.g., lentiviral), arthropod disease vectors (e.g., mosquitoes), or something else?

vi. Gene drive modified biological agents is not defined and is a confusing term. Biological agents in the Policy are defined as bacteria, viruses, fungi, or parasites, yet gene drive technology requires Mendelian genetics, such that this would be limited to fungi or parasites. The subsequent use of GDMO in this category suggests that gene drive modified biological agents are different from GDMOs, but this delineation is not clear.

vii. GDMOs are not defined in the Policy.

viii. **We recommend** that this category be removed from the Policy or extensively re-written, as described below.

1. The definition for Genetic Modification should be re-written to be limited to stable alterations in the genome. Definitions for organism, vector, GDMO and gene drive modified biological agents must be added to the Policy (or removed).
2. Research with genetically modified risk group 3 and 4 biological agents should be approved by the IBC. Research with genetically modified risk group 2 biological agents should be approved by IBC delegate.
3. Research with GMDOs should be approved by the IBC.
4. Review and approval of research with genetically modified cells should be dependent on the modification, some of which may fall within IBC approval, delegate approval, or be completely exempt from the Policy.

i. **Section IV-2:** ***Research with primary cells that may be contaminated by adventitious agents.***

i. As noted above, the Policy does not define adventitious agents. Therefore, entities will be uncertain how to comply with this regulation and will rapidly be in noncompliance.

ii. If the intention of the Policy is to regulate primary cells that may be contaminated by bloodborne pathogens, there is a significant risk assessment issue: research with samples that may be contaminated requires full IBC review, yet research with known RG2 biological agents requires delegate review.

iii. For clinical samples suspected to contain higher consequence pathogens (*Brucella*, Herpes B, *M. tuberculosis*, etc.), the BMBL states that BSL2 practices, containment equipment, and facilities are recommended for routine

handing of clinical specimens of human or animal origin. The Policy should harmonize the level of review required for these samples: at most they should require delegate review.

1. **We recommend** that this section be removed from the Policy.
2. **If it must be regulated by the Policy,** "adventitious agent" must be clearly defined within the Policy.
3. **If it must be regulated by this Policy, we recommend** that this work not require IBC or delegate approval as long as the entity is complying with OSHA Bloodborne Pathogens Standard or its equivalent.
4. **If it must be regulated by this Policy, we recommend** that it should not fall under the category of requiring IBC approval and should at most be in Section IV-3, where delegated review is permitted.

iv. If the intention of the Policy is to regulate primary cells that may be contaminated by any unknown biohazard (for example field samples), that is not clear and needs to be much more clearly defined.

j. **Section IV-2: *Research with wild type or genetically modified RG2 biological agents for which lower containment is requested, or research with wild type or genetically modified RG3 or RG4 biological agents that NIH has previously approved to be conducted at lower containment.***

i. The Policy implies that there will be a workflow of (1) an entity submits an initial request for NIH to lower containment involving wild type or genetically modified RG3 or RG4 biological agents, (2) NIH will make a determination on whether that lower containment is appropriate, (3) NIH will be responsible for publishing approved determinations of appropriate lower containment for these agents, (4) subsequently, research involving these agents may be approved by the IBC alone (without NIH approval).

1. This workflow should be expressly stated in the Policy to minimize confusion. This includes a clear statement that once NIH has made the determination and published it, other entities will not be required to obtain NIH approval. This would be in contrast to the current system, where approvals are provided only to the single PI at the single institution.
2. The method by which NIH will publish these determinations should be described, including the minimum time frame (determinations will be published within 1 month, within 6 months, annually, etc.).
3. The Policy should be clear on how much information will be released together with these determinations. Specifically, whether the information includes security sensitive information or unpublished data.

k. **Section IV-3 (Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members): *Research involving RG2 wild type biological agents.***

i. We have no objection to including RG2 biological agents within scope of the Policy, as our institution already requires that work with these agents be approved by the local IBC.
ii. However, we are very concerned that there is not a thorough list of RG2 biological agents and/or biological agents that are recommended to be worked with at BSL2. Will all agents not listed in the BMBL require review by NIH?
iii. **We recommend** that the NIH make a detailed, publicly available list of RG1, RG2, RG3, and RG4 biological agents to supplement the BMBL. Appendix B of the *NIH Guidelines* should serve as the backbone of this document.
    1. The inclusion of RG1 organisms is an important part of such a list, since they are outside the scope of the Policy, yet the Policy specifically states that "absence of agent specification in the list of RG2-RG4 does not imply automatic or implicit classification as RG1".
    2. If other federal entities (USDA, CDC, etc.) participated in creating a central list that also includes plant or agricultural considerations, that would be greatly appreciated.
iv. If NIH cannot make a detailed publicly available list of RG1, RG2, RG3, and RG4 biological agents to supplement the BMBL, **we recommend** that the Policy clearly states that the local IBC has the authority to perform the risk assessment and make that determination.

l. **Section IV-3: *Research conducted with transgenic organisms at BSL-1/ABSL-1.***
    i. The purchase and transfer of transgenic rodents requiring BL1 containment is exempt in the NIH Guidelines (Appendix C-VII). Further, the generation of certain BL1 transgenic rodents is exempt in the NIH Guidelines (Appendix C-VIII). In 2011, NIH deemed that "… these breeding experiments do not pose an appreciable risk to human health or to the environment. In addition, while registration with the IBC is not a significant burden, the total number of registrations required can constitute a significant collective administrative burden on the IBC and researchers that does not appear to be commensurate with the very low biosafety risk." (January 19, 2011, Federal Register, January 19, 2011 (76 FR 3150)). As documented in NIH guidance documents, the subsequent use of these BL1 transgenic rodents is also exempt (https://osp.od.nih.gov/wp-content/uploads/2022/11/Animal_Activities_Table.pdf). The same risk assessment should apply today, and the Policy should not require that work with transgenic rodents that can be housed at ABSL1 be approved by the IBC.
    ii. As noted previously, there is no definition of *organism* in the Policy. Therefore, **we recommend** changing this to *animal* in this section.

iii. We understand that research with some transgenic animals may not have had the time to demonstrate the same safety track record as transgenic rodents and therefore should continue to require IBC approval before that research is conducted. We would recommend that NIH seriously consider that transgenic fruit flies or zebrafish could be exempted due to their safety track record.
iv. **We recommend that this be re-written as:** Research conducted with transgenic animals, other than transgenic rodents, fruit flies, and zebrafish that may be housed at minimum BSL-1/ABSL-1/ACL-1.

m. **Section IV-3: *Research with genetically modified RG1 biological agents.***
   i. Certain research not requiring NIH-OSP approval and not involving DNA from RG3, RG4, or restricted organisms with specific risk group 1 biological agents is exempt in the NIH Guidelines (Appendices C-II, C-III, C-IV, and C-V), having been determined by the NIH Director to not present a significant risk to health or the environment. The Category here (research with genetically modified RG1 biological agents) contradicts this determination and would require that work that was previously exempt now requires IBC approval. The Policy has not described why this risk assessment has changed.
   ii. **We recommend that this category be removed from the Policy.**
   iii. Additionally, a list of RG1 biological agents is not available. If any part of the Policy references RG1 biological agents, including as work that is outside the scope of the Policy, a list should be developed and published by NIH as part of this Policy, or the local IBC should be granted the authority to designate agents as RG1.

n. **Section IV-3: *Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes.***
   i. This category of research is of low biosafety and biosecurity risk. The Policy fails to describe how regulating this research will increase biosafety or biosecurity. This category will set entities up for failure, with no clear benefits to our biosafety programs.
   ii. Registering research with plasmids will lead to extensive unintentional noncompliance. Researchers generate plasmids regularly and the requirement to obtain approval for these plasmids from the IBC will be a severe bottleneck.
   iii. The Policy fails to describe the extent of what is required to be registered as part of this section. Only the plasmid backbone? The backbone with every gene the researcher will insert? The backbone with every gene and every mutation of that gene?
   iv. The administrative burden for researchers and the IBC will be significant and is not balanced by any increase in biological safety.
   v. **We recommend that this category be removed from the Policy.**

o. **Section IV-3: *Research with well-characterized cell lines.***

i. Registering work with well characterized cell lines will lead to extensive unintentional noncompliance. The administrative burden will be crippling for researchers and IBCs. This category will set entities up for failure, with no clear benefits to our biosafety programs.
ii. The Policy fails to describe the biosafety concern that is being addressed by this category of research.
iii. The Policy does not describe the extent of what is required to be registered. It is solely that a researcher is performing work with cell lines? Is it every cell line that the researcher will work with? May the entire ATCC catalogue be approved?
iv. **We recommend that this category be removed from the Policy.**

p. **Section IV-3: *Research with biological toxin proteins not on the Select Agent list*.**
   i. Under the definition within the Policy, this category includes food allergens, animal allergens, even FBS, since they can cause harm to humans, yet there is no indication that this is intended. The milk that a researcher is using as part of a Western blot falls within scope of this category.
      1. There is a conflict between the wording in this Section (research with biological toxin proteins) and the definition in the Policy for Toxin (a protein or peptide produced …). This conflict makes it difficult to understand what is within the scope of the category.
   ii. This category of research must include a clear definition of which toxins are within scope, including an LD_{50}, or entities will be inadvertently noncompliant.
   iii. At our institution, work with toxins are already regulated by our Chemical Safety Committee, which provides regulatory oversight of this work. Additional oversight by the IBC will not increase safety and will instead increase regulatory burden.
   iv. **We recommend that this category be removed from the Policy.**
   v. **If this category is not removed, we recommend that this be re-written as:** Research with biological toxin proteins with an LD_{50} in vertebrates of <100 micrograms per kilograms of body weight.
      1. Additionally, a list of toxins currently classified under this category must be provided in the Policy. The list of toxin molecules classified as to LD_{50} that is currently available from NIH OSP under the *NIH Guidelines* (Appendix F-1) should serve as the backbone of this list.

3. **Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).**
    a. **Risk Groups as Hazard Characterizations vs. Site-Specific Risk Assessment**
        i. Risk Groups remain valuable tools for initial hazard communication and agent characterization, but they should not independently dictate containment or review levels. The final policy must preserve site-specific and experiment-specific assessment of agent characteristics, procedures, scale, routes of exposure, personnel expertise, facilities, and available mitigations. This aligns with Section V-E of the draft policy, which explicitly acknowledges that Risk Groups and Biosafety Levels are related but non-equivalent concepts.
    b. **Critique of Mandatory IBC Petitions for Emerging, Novel, or Unlisted Agents (Section III-B)**
        i. The 'IBC Functions' section (fifth bullet) directs the IBC to petition NIH to determine the minimum biocontainment level for emerging, novel, or zoonotic agents 'for which the RG classification or containment level is not available in the BMBL,' prohibiting IBC approval until authorized by NIH and any other applicable entities.
        ii. **Terminology Inconsistency:** The draft text treats 'RG classification' and 'containment level' as alternative terms residing in the BMBL. However, Section V-E correctly states that RGs and BSLs are non-equivalent. NIH must use these terms consistently across all policy sections.
        iii. **BMBL Functionality & Misconception:** The Biosafety in Microbiological and Biomedical Laboratories (BMBL) manual does not assign Risk Groups; it provides Agent Summary Statements with recommended Biosafety Levels. A regulatory condition referring to an RG classification 'in the BMBL' cannot be fulfilled.
    c. **Jurisdictional Ambiguity:** The phrase 'and any other applicable Federal, State, or local entities' introduces immense ambiguity. NIH must explicitly identify these entities, specify whether approvals are sequential or concurrent, clarify coordination protocols, and establish resolution pathways when determinations conflict.
    d. **Overbroad Scope & Unintended Petition Backlogs:** As written, the petition requirement could be interpreted as applying to non-pathogenic genetically modified constructs or benign RG1 organisms that are not explicitly named in the BMBL. NIH must explicitly clarify that unlisted, non-pathogenic RG1 agents do not require federal petitioning.
    e. **Reusable Determinations & Response SLAs:** Section III-D commits NIH to publishing determinations for lowering RG3/RG4 containment but omits

determinations for emerging or novel agents. NIH should publish all containment determinations (agent, modification, approved containment, and rationale) in a searchable public database that other institutions may rely upon as established precedent. Furthermore, NIH must set a target response timeline (e.g., 30 calendar days) rather than relying on the subjective term 'timely.'

f. **Definitive Source for Risk Group Assignments**
With Risk Group assignments removed from the former Appendix B and absent from the BMBL, NIH must provide an authoritative, version-controlled federal repository or clear objective criteria for assigning Risk Groups to non-recombinant agents. Without standardized federal classifications, institutions will reach conflicting conclusions for the same agent, compromising national oversight consistency.

g. **Avoid Rigid Containment Prescriptions (GDMOs and Influenza Research)**
Rigid, one-size-fits-all containment rules conflict with performance-based risk assessment. A universal minimum of BSL-2 for Gene Drive Modified Organisms (GDMOs) does not map effectively to specialized containment systems (e.g., Arthropod Containment Level [ACL] guidelines, USDA/NCAR Greenhouse standards, or aquatic facilities). NIH should permit equivalent risk-based containment modalities and issue specialized guidance. Additionally, containment mandates for influenza constructs should specify exact phenotypic traits, host range, and pathogenicity markers rather than sweeping in constructs based on raw genomic segment proportions.

Summary of Requested Regulatory Modifications

Topic Area	Draft Policy Flaw	Requested NIH Modification
Risk Groups vs. BSL	Treats RGs as mandatory containment triggers rather than hazard descriptors.	Explicitly confirm in Section V-E that RGs do not independently dictate BSLs; preserve local risk assessment.
BMBL & Petition Scope	Cites RG lists in BMBL (which do not exist) and lacks scope limits.	Correct BMBL reference; exclude non-pathogenic RG1 agents from mandatory federal petitioning.
Federal Precedents	No commitment to publish determinations for novel/emerging agents.	Publish all containment decisions in a searchable public database with a 30-day target review timeline.
GDMOs & Influenza	Applies universal BSL-2 to GDMOs and rigid segment ratios to Influenza.	Allow specialized containment (ACL, Greenhouse, Aquatic) and calibrate Influenza rules to phenotype.

4. **Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions).**
    a. No comments at this time.

5. **Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.**
    a. Refine the definition of a reportable incident and provide clearer thresholds for reporting to support a risk-based, consistent approach across institutions. Clear thresholds improve consistency and allow NIH to focus regulatory oversight on events with true potential public health or community significance.
    b. **Decouple Regulatory Reporting from Public Website Posting**: Requiring institutions to publicly post unredacted investigative reports and meeting minutes for routine or minor incidents creates severe unintended consequences:
        i. Publicly posted incident reports inadvertently provide sufficient detail to identify involved personnel.
        ii. Publicly linking Principal Investigators, grant numbers, and specific facility locations exposes researchers to harassment, physical threats, and targeted cyber-attacks, particularly in sensitive animal research domains.
        iii. Aggregated public postings reveal institutional research security information. Automated AI scraping tools can harvest these public records to map national high-consequence research capabilities, directly conflicting with federal research security directives and Select Agent regulations.
        iv. Forcing minor, fully mitigated events into public view suppress internal reporting of near-misses and borderline events out of fear of public backlash or reputational damage.
    c. **Resolving Undefined Categories & Technical Definitions**: To eliminate ambiguity, prevent administrative overload, and protect local reporting culture, NIH must establish precise definitions for the following core terms in Section II:
        i. **Incident:** A confirmed theft, loss, or release (such as an occupational exposure or a release outside the defined biocontainment barriers) of biological material under the scope of the Policy.
        i. **Release (Loss of Containment or Occupational exposure):** Release means a failure in biosafety practice and/or equipment such that there is occupational exposure of the person(s) working in the laboratory, and/or escape of the biological material beyond the defined biocontainment boundary.
        ii. **Basic First Aid vs. Agent-Specific Medical Treatment:** NIH must explicitly align medical treatment with OSHA standards (care beyond basic first aid). NIH must clarify that precautionary, non-specific post-exposure prophylactic (PEP) treatment or routine medical consultations do not constitute agent-specific treatment triggering 24-hour federal reporting.
        iii. **Potential Exposure:** Must be defined as an event occurring in the active presence of a biohazard where primary barriers or PPE were breached, creating a credible exposure pathway. Equipment or PPE failures occurring in the absence of active biohazardous agents are not potential exposures.

iv. **Compliance Violation vs. Administrative Non-compliance:** Must distinguish administrative non-compliance (e.g., late paperwork, minor log errors) from substantive biosafety non-compliance (e.g., unapproved research initiation or unauthorized containment lowering). Administrative non-compliance and low-risk items must NEVER necessitate a 24-hour reporting timeframe.
v. **Minor Spill:** Must remove subjective terms like generally and define minor spills.

d. Institutions vary in their meeting structures, recordkeeping practices, information systems, and use of software platforms that may automatically generate meeting records or summaries.
   i. NIH should require the specific content elements needed to support transparency and accountability, such as review category, approval decision, containment level, and required conditions, rather than mandate a rigid template. A content-based approach would allow institutions to use existing processes and technologies while ensuring that required information is consistently documented and made publicly available, subject to appropriate protections for sensitive information. NIH should also provide flexibility in the documentation format of public meeting minutes and incident reports.

6. **Feedback on the implementation resources and areas in which additional guidance would be beneficial.**
    a. **Provide risk assessment guidance for self-aggregating proteins (**Policy Sections II and V-A). The definition already limits prions and self-aggregating proteins to misfolded forms that self-propagate and cause neurodegenerative disease. Provide practical examples and risk assessment guidance for applying that definition, including how to distinguish in-scope materials from ordinary physiological protein aggregation.
    b. **Clarify oversight of computational and AI assisted work (**Policy Sections II and V-C). Clarify whether purely computational design of a novel biological agent, without synthesis or experimental manipulation, falls within the Policy's definition of laboratory research. Distinguish this question from risk assessment of physical agents designed with computational or AI tools. Provide practical guidance on evaluating the resulting biological hazards and identifying when additional expertise is needed.
    c. **Provide a minimum 24-month phased implementation period** The proposed six-month effective date is not realistic for institutions that must inventory newly covered research, obtain an approved Biosafety Assurance, revise policies, redesign electronic systems, build public-facing processes, establish redaction standards, revise incident workflows, train affected communities, secure institutional approvals and funding, or in some cases establish an entirely new IBC. NIH should provide at least 24 months after publication of the final policy and complete implementation materials, with phased milestones and provisional or deemed assurance mechanisms that prevent interruption of ongoing research.
    d. **Pilot the policy and templates**: NIH should pilot the assurance, meeting-minutes, incident-reporting, risk-assessment, and delegated-review tools with institutions representing different sizes, missions, research portfolios, and program maturity. Pilot findings should be published and used to refine burden, clarity, and usability before requirements become mandatory.
    e. **Develop implementation resources**: Needed resources include a Biosafety Assurance template; model policies; decision trees; risk-assessment forms and worked examples; training material for IBC members, BSOs, PIs, and staff; sample completed minutes and incident reports; clear redaction guidance; a national Risk Group and containment determination database; and guidance for external, shared, and consortium IBC models.
    f. **Address the cost of compliance:** The policy should not operate as an unfunded mandate. Other regulatory agencies are required to assess financial impact of policy changes, in lieu of this, NIH should consider dedicated biosafety funding supplements, explicit allowability of appropriate biosafety costs in direct or indirect

cost structures, workforce development programs, shared training resources, and implementation support targeted to smaller and less-resourced institutions.

g. **Allow flexible institutional models**: The final policy should expressly permit shared or consortium IBCs, external IBC services, and mutual-aid arrangements. Requirements for unaffiliated members and specialized expertise should be flexible enough to remain workable in small, rural, geographically isolated, or institution-dominated communities while preserving meaningful independent input.

I thank NIH for allowing us the opportunity to provide comments on this Draft Policy. We look forward to seeing a second draft of the Policy and will remain fully engaged in this process.

Uploaded File: Response-Draft-NIH-Biosafety-Policy-1.pdf

Description: Response -Draft -NIH-Biosafety-Policy

The Draft NIH Biosafety Policy for Research Involving Biohazards (the Policy) is intended to be an update to the existing NIH Guidelines for Research Involving Recombinant and Synthetic Nucleic Acid Molecules (NIH Guidelines). However, the result is a policy that presents a confusing mixture of incomplete rules that ignores many key features of the NIH Guidelines that were crafted and refined over decades of consideration and interpretation. The new policy was an attempt to streamline the oversight of the Institutional Biosafety Committee (IBC) and provide more authority. Unfortunately, the ambiguity and lack of examples create greater confusion where little to none had existed.

The Policy shifts the focus of its oversight to human-centric pathogens in a way that ignores the potential negative economic and societal outcomes of pathogens that infect animals and plants. While the Policy states that pathogens infecting animals and plants will be addressed by policies from other agencies, the lack of such policies is very notable and concerning. It is strongly recommended that the Policy reconsider the absence of animal and plant pathogens that do not infect humans to ensure appropriate and consistent oversight is provided.

The Policy sets forth an extremely aggressive timeline for implementation and compliance. Institutions will have six months from Policy publication to implement all changes. The Policy fails to provide a framework for how ongoing basic sciences research and clinical research that is subject to the NIH Guidelines will be impacted. For example: will review/approval of research by the IBC be halted pending acceptance of the institutions AOR assurance by the NIH? Moreover, guidance will necessarily change for how institutions will handle HGT studies (which are not directly referenced or redefined in the Policy) and how IBCs are expected to work with the local Institutional Review Board (IRB)

Compliance with this policy will require changes in institutional policy, training materials, printed materials, and significant changes to oversight systems. Electronic systems that are employed to ensure compliance with applicable federal policies are often managed and updated by third-party companies. Institutions will be dependent on the speed with which these companies will be able to complete the necessary changes. Making changes will also be dependent upon accurate interpretation of the Policy, which will likely not be settled by the time it is published. The time and financial costs of making such changes will be significant.

The Policy is also being implemented within a similar timeframe as the United States Government Policy for Stopping High-Risk Life Sciences Research (DGOF Policy). There is a high degree of overlap between these policies but nuanced differences will make implementation of both policies at the same time an incredibly difficult burden on both research professionals and administrative staff. Moreover, the Policy states that institutions must demonstrate compliance within 6 months of implementation but no description of how compliance will be demonstrated.

There are noted gaps within the definitions provided within the Policy that are cause for concern. In particular, the definition of Biological Agent focuses on agents that cause disease in healthy individuals. This definition does not account for microorganisms that are commensal in humans but may exacerbate health conditions if exposure occurs. Agents that cause disease in humans are worth studying, and therefore providing oversight, due to their potential to cause disease in humans if certain conditions are met or fortuitous genetic modifications naturally occur. This definition also does not encompass agents that do not cause disease in humans but enhance the pathogenicity of the bacteria they infect, e.g., phages.

The focus on agents that cause disease in humans is also concerning because the ecosystem is broad and includes animals. Biological agents that are infectious to animals or plants but not humans could have significant societal and economic impacts. Absent guidance from other, relevant agencies, it is unclear how oversight will be provided to these agents.

The definition of toxin is also ambiguous as it does not describe what is meant by harm to a human. Some small proteins, such as allergens, are not toxic but are still capable of causing acute harm or harm following long-term exposure. Overall, the definitions need to be more descriptive and less available for interpretation.

Similar to the definitions section, the roles and responsibilities section, Section III, would greatly benefit from more precise and descriptive language as well as examples of how to implement this policy. Examples should be provided for biosafety assurance, posting minutes, reporting and posting incidents, and specific training requirements. The requirement for a Biosafety Officer (BSO) is also unclear: some sections state that it is required for research at BSL3 and higher while other sections state that a BSO is required for research with organisms that are Risk Group (RG) 3 and higher. These statements are incongruous and conflate Risk Group with Biocontainment Level. Moreover, many responsibilities are assigned to the BSO throughout this policy despite the fact that the position is not formally required in most instances when such work will be conducted (at BSL2 and below). Additional guidance regarding what responsibilities the BSO may delegate and to whom would also be helpful.

This section also states that the NIH must be petitioned to determine the appropriate biocontainment level or reduce the biocontainment level for RG3 and RG4 organisms *each time* a request is made. Lentiviral vectors are ubiquitous in life sciences research despite the parent organism earning a RG3 rating. Nevertheless, these agents are typically handled at BSL2. Will the NIH be providing a blanket downgrading of these agents to BSL2? Will such a request be granted at an institution level? Or would downgrading such organisms require a different request dependent upon transgene?

The role and responsibilities of the Principal Investigator (PI) are also outlined in this section but would benefit from additional clarity. This section states that the PI must initiate the risk assessment process. Guidance for how this should be documented would support this process. The PI is required to submit amendments when biorisk

changes but this section does not provide guidance for how the alteration (or increase) in risk is determined. Lastly, additional guidance regarding the PI's responsibility to submit voluntary safety/near miss information would be appreciated and if this information should be relayed through the BSO and/or the IBC and/or another institutional official.

This section should also provide guidance about how the NIH will assign containment levels for both novel and existing biological agents. There is some information about this process, however, it is buried in four short bullet points at the end of the document and provides insufficient guidance. Additional guidance should also be provided regarding so-called "low" or "high" risk activities. These qualifiers for risk are relative and cannot be consistently applied. Administrative and engineering controls are intended to reduce risk before a researcher even begins work. Thus, risk is inherently lower with well-trained staff and well-appointed facilities. Moreover, some research institutions are more risk-tolerant than others.

The Policy should also consider bringing forward major tenants of the NIH Guidelines that continue to be relevant. For example, the Policy no longer explicitly prohibits cloning of clinically relevant drug selection markers into human pathogens. While this activity would likely be prohibited or heavily regulated by the DGOF Policy, that policy is not directly referenced and should be. Moreover, the structure of the NIH Guidelines that clearly defines categories of research and the approval required for each should be considered for the Policy. These categories for research provide concrete examples for researchers when determining the type of research they are conducting and guidance for biosafety professionals and IBCs when reviewing and approving such research.

While it can be generally agreed upon by biosafety professionals that the NIH Guidelines needed to be reconsidered, one major benefit to the aged document is the iterative process of defining and redefining research categories. This process has occurred throughout the lifetime of the document and is thanks to diligent, considerate, and critical researchers and biosafety professionals. In contrast, this Policy significantly lacks the clarity of research categories that the current NIH Guidelines provides. Each section of research that is covered in Section IV of this document needs to provide concrete examples of the categories to ensure appropriate and consistent application. Consistency of application is of critical importance to ensure overall compliance and reduce confusion among research staff and research programs writ large.

Re: Request for Comment on Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear NIH Office of Science Policy:

The George Washington University (GW) appreciates the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. As a leading research university with a strong commitment to biosafety, regulatory compliance, and the responsible and ethical conduct of research, GW supports efforts to modernize biosafety oversight and establish a comprehensive framework that reflects the evolving nature of biological research.

GW shares the concerns expressed by ABSA International (the Association for Biosafety and Biosecurity) in their comments submitted to NIH's Office of Science Policy. ABSA International represents the nation's leading biosafety professionals and provides critical expertise regarding the practical implementation of biosafety policies within research institutions. We urge NIH to carefully consider and incorporate ABSA's recommendations as it develops the final policy.

While GW supports the overarching goals of strengthening biosafety and promoting transparency, we have several concerns regarding specific provisions of the draft policy. Informed by the expertise of GW investigators, research safety administrators, and regulatory committee members, we offer the following additional comments on the proposed NIH policy.

IBC Approval Periods
GW is concerned by the proposed requirement that Institutional Biosafety Committee (IBC) approvals be granted for periods not to exceed three years, requiring a de novo review and submission at the end of each cycle. The current five-year approval framework has supported effective oversight while allowing our institution to focus resources on risk assessment, compliance monitoring, laboratory inspections, protocol amendments, and investigator engagement.

Reducing the approval period to three years would substantially increase administrative burden for the institution, investigators, and the IBC without a demonstrated corresponding improvement in biosafety outcomes. The proposed change would require the review and resubmission of many protocols that have undergone no significant changes in risk profile, diverting institutional resources from important oversight activities. GW encourages NIH to retain the existing five-year approval cycle or evaluate a tiered approach that considers a project's risk and complexity.

Incident Reporting and Public Posting Requirements
GW supports robust incident reporting systems and recognizes the value of transparency in strengthening biosafety practices. However, several aspects of the proposed reporting and public disclosure requirements may create unintended consequences that could undermine a strong culture of safety.

1922 F St, NW, Suite 422 | Washington, DC 20052
t 202-994-6255 | f 202-994-9137 | research.gwu.edu

The draft policy would require extensive public posting of incident reports, IBC meeting materials, and compliance-related information while also creating new reporting expectations for compliance deviations and other biosafety events. Institutions thrive when investigators and laboratory personnel feel empowered to promptly report mistakes, near misses, and possible noncompliance so that corrective actions can be taken and lessons can be shared.

The combination of expanded reporting obligations, public disclosure requirements, and potential enforcement implications may discourage voluntary self-reporting and create a more punitive perception of biosafety oversight. We encourage NIH to carefully evaluate how these provisions may affect institutional reporting behaviors and to ensure that the final policy continues to incentivize the prompt identification and correction of biosafety concerns.

In particular, GW recommends that NIH provide additional clarity regarding the distinction between mandatory reporting requirements and voluntary submissions to the proposed National Biosafety Data and Safety Analysis Center (NBDSAC), including how submitted information will be protected, de-identified, secured, and used.

Additional Clarifications

GW also encourages NIH to provide greater clarity regarding the interaction of this policy with oversight conducted by other federal agencies, the scope of federal review requirements for higher-risk research, and the application of the policy to activities involving non-protein biological toxins and other biohazards that are not fully captured by the current definitions.

GW appreciates NIH's engagement with the research community throughout this process and supports the agency's goal of creating a modern, risk-based biosafety framework. We urge NIH to work closely with institutions, biosafety professionals, and stakeholder organizations such as ABSA International to ensure that the final policy enhances biosafety while remaining practical and sustainable for the research enterprise.

Yours sincerely,

Evangeline J. Downie, Ph.D.
Interim Vice President for Research

464. William Peairs

I am responding: On behalf of myself

Name: William Peairs

Name of Organization:

Type of Organization: Not Applicable

Role: Other

Role - Other: Biosafety Officer

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I am submitting these comments in my personal capacity as a biosafety professional. The views expressed are my own and do not represent my employer or any Institutional Biosafety Committee on which I serve. This statement applies to the entire submission.

I appreciate NIH's effort to address biosafety across biomedical research. Broader coverage can help institutions consider hazards beyond recombinant and synthetic nucleic acids. To apply that coverage consistently, institutions need clear criteria for deciding which activities fall within the policy.

Scope

Please explain how the threshold of known or potential risk to human health limits the listed material categories. Applying that threshold to routine research can be less straightforward than identifying the hazards of work involving a known pathogen.

Consider an experiment introducing a low-risk reporter into a well-characterized cell line by electroporation or nucleofection, without an infectious delivery vector. The absence of a viral vector does not resolve every hazard question, but it makes the basis for identifying human-health risk important.

Would this activity be covered because the cells are genetically modified, or must there also be an identifiable basis for known or potential harm? What information supports that determination? Such work can reasonably fall within an institution's biosafety program, but that does not resolve whether federal review requirements apply. Without a clear rule, equivalent work could be excluded at one institution and require approval at another.

Definitions and review categories

Please explain which characteristics distinguish primary materials from well-characterized cell lines for oversight purposes. Compare recently collected human cells, primary cells expanded in culture, and an established line carrying a low-risk reporter. Which facts change applicability, review route, or precautions? These are separate decisions, and a designation such as “established” may not answer all three.

Guidance should explain how to make these decisions when infectious status is uncertain. A sample known to contain HCV presents an identifiable agent-specific hazard. Cells from an apparently healthy donor, or an established line without relevant testing, present different questions about possible adventitious agents. What information is sufficient, and when is additional characterization or testing expected?

My primary concern is the feasibility of making sound decisions in the face of uncertainty, rather than whether the requirements err on the side of caution or permissiveness. If additional testing or characterization is expected, please make clear when and why, and what information is sufficient to reach a decision.

Please also provide practical criteria for applying the definitions of genetic modification and disease-causing self-propagating proteins. For proteins, the definition identifies a hazardous property, but institutions need to know how to evaluate preparations whose capacity for self-propagation or disease is uncertain. Routine protein expression should not require a speculative assessment of whether every expressed sequence could produce a hazardous misfolded protein. Examples and practical screening criteria would help identify preparations warranting closer review.

Gaps in oversight

Researchers have different levels of biosafety expertise and differing risk tolerance. They may describe work as harmless because hazards are low, protective measures are effective, or relevant risks are unfamiliar. Those explanations have different implications.

Please permit institutions to apply defined screening criteria and escalate consequential uncertainty, rather than rely solely on investigator self-classification. Routine activities should not each require a separate formal determination merely to establish that they are outside scope.

Other federal oversight

Please reconcile the provision allowing research to proceed under another federal agency’s oversight with the clinical-review requirements. Specify which NIH-policy obligations remain after the other agency’s applicable approvals or clearances have been obtained.

My concern here is clarity about the requirement itself. As written, I cannot confidently determine what remains required, and I would greatly appreciate an explicit explanation. A worked clinical example would be particularly helpful.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I welcome the use of different review tiers. A simpler route for lower-risk work can direct more attention toward activities with greater uncertainty or consequences. The assessment and documentation requirements should preserve that benefit throughout the process.

Proportionate assessment

Please state expressly that a comprehensive assessment considers all relevant hazards, with the depth of analysis and documentation appropriate to the work. A complete assessment of a simple activity may be brief, even when another activity in the same review tier requires substantial analysis. Examples should demonstrate sufficient assessment without equating thoroughness with document length.

Administrative updates and minimal risk activities

Section III-B links amendment approval to changes that may affect the original biosafety assessment. Please confirm that authorized staff may record updates without that effect, such as a change in an administrative contact, without delegated scientific approval.

I also recommend a screening or registration pathway for defined minimal-risk activities without individual IBC approval. Institutions should establish criteria and responsible personnel, with reconsideration when relevant facts change. Delegation alone can save committee time while leaving most staff work intact or increasing administrative requirements.

Established controls

Please expressly permit assessments to incorporate approved institutional procedures by reference. The record should identify the work, explain why the controls apply, and describe departures or additional precautions. Project-specific factors and decisions should receive the emphasis.

Explicit permission would help institutions confidently use this approach rather than reproduce standard procedures in every assessment.

Incident reporting and disclosure

These are my greatest concerns. Effective accountability depends on reliable information and prompt, candid reporting. I am concerned that requiring full investigations and public reports for covered minor incidents and isolated administrative errors could make the process appear punitive, discourage reporting and cooperation, and erode the trust that a strong safety culture requires. The policy should establish when a full investigation is warranted and when a simpler review and response are sufficient.

Requirements should distinguish administrative noncompliance from exposures or releases with material safety consequences. The required investigation, documentation, and corrective action should reflect the event's significance. Repeated lapses, uncertain controls, or unreviewed changes warrant closer attention, but an isolated administrative lapse should not automatically require the same response as a

serious containment failure.

Please separate detailed oversight records from public accounts. Significant events should receive timely public summaries explaining what happened, actual or potential consequences, the response, corrective actions, and follow-up. Defined minor events should be eligible for concise or grouped accounts, with fuller records retained for oversight and inspection.

OSHA's distinction between detailed injury records and its Form 300A workplace summary offers a useful design analogy. The aim is meaningful accountability with appropriate protection for affected people. If detailed public reports remain required, specify proportionate content for different event categories and protect against identification through combined details.

3. Continued utility of Risk Groups: Risk Groups provide a useful starting point for understanding agent hazards, while Biosafety Levels describe precautions for particular activities. Preserving that distinction supports sound assessment without requiring institutions to assign an agent classification to every biological material.

Please address a common situation: mice are administered human cells, no specific infectious agent is known to be present, and bloodborne-pathogen precautions are used because infectious status is uncertain. A qualified reviewer subsequently evaluates documented characterization or testing that supports reduced precautions for the material.

Would selecting lower containment for subsequent animal housing require full-committee review under the provisions for lowering containment of RG2 agents, even though the initial precautions address uncertain infectious status rather than an identified agent, or could the decision receive delegated review? Would the answer differ if the housing conditions were established during the original approval rather than proposed later as an amendment?

The initial precautions address possible contamination; they do not establish that an RG2 agent is present. Conversely, negative test results do not establish absence of every possible pathogen or automatically justify lower animal containment. Please explain what evidence and documentation are sufficient to make this decision, while preserving professional judgment about relevant testing and remaining uncertainty.

OSHA's June 21, 1994 interpretation recognizes documented characterization of certain human cell cultures when determining Bloodborne Pathogens Standard coverage. Please explain how such evidence may inform the separate NIH assessment, without treating an occupational-safety determination as an automatic animal-containment decision.

A worked example should identify the appropriate review route and when full-committee or federal approval is required. Clear guidance would support consistent decisions without creating a universal testing panel or assigning a Risk Group solely because precautions were initially used.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Making practical biosafety resources available beyond NIH-

funded institutions is a useful part of this effort. Accessible training, technical consultation, assessment tools, and worked examples could provide clear benefits to organizations choosing to participate voluntarily.

I encourage NIH to develop these resources with their intended users and support staged adoption of useful practices. A voluntary incident-learning system could also help institutions share lessons and prevent recurrence. I would welcome a resource comparable to NIOSH, focused specifically on biosafety lessons and prevention (my impression is that's the plan, so I wish you the best of luck!).

Clear explanations of how confidentiality and de-identification operate, and how voluntary submissions are distinguished from mandatory reports, would help contributors understand the protections and responsibilities involved. Straightforward participation and visible benefits would support continued engagement.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Standard templates can improve consistency and make oversight easier to understand. Their instructions should show how sufficient information varies with the event or review and permit equivalent documents generated from existing systems.

Incident reporting

Please distinguish the information expected for initial notification, the completed investigation, and public accountability. Those purposes may require different levels of detail. Building on the template's distinction between initial and final reports, please specify what belongs in each stage and what must be included in the public account.

Requiring the same detailed account for different purposes can create unnecessary disclosure and administrative work without improving the information available for oversight.

Please provide completed examples for an administrative approval lapse, a minor event reviewed locally, and a serious exposure or release. Allowing "not applicable" is helpful, but institutions also need examples of sufficient analysis.

The current template does not appear well suited to administrative matters. For an overlooked renewal, what would constitute a sufficient root-cause analysis and corrective-action response? A completed example should demonstrate the expected depth of explanation and when a brief account is adequate. This would support useful corrective action without encouraging lengthy narratives that add little understanding.

Lower risk events and duplicate public records

The paragraph requiring local review of lower-risk events does not specify use of the incident template, while the later posting provision appears to require it broadly. The full template does not appear well suited to many of these events. Please clarify whether a full investigation and separate template-based public report are required for lower-risk events, and explain what information is actually needed.

I recommend allowing a concise account in publicly posted minutes to satisfy the public-record requirement for defined lower-risk events, without a separate full-template report. Specify the necessary information, including the event's significance, the IBC's review, the response, and preventive action. This would preserve accountability while avoiding duplicate public documents describing the same review.

Please also permit periodic grouped summaries, such as quarterly summaries, for defined recurring minor events where individual narratives add little information. These could complement the minutes, using a summary approach analogous to OSHA Form 300A. Detailed institutional records should remain available for oversight and inspection, with the same privacy protections applied regardless of the public format.

Privacy and unpublished information

I appreciate the permission to protect private and proprietary information. However, details already available elsewhere can identify an affected employee when combined with an incident narrative. A PI's identity, project description, role, date, and medical information may together reveal who was involved.

Please permit omission or generalization when the combination creates a meaningful identification risk, even if individual details are otherwise public. Instructions should reconcile this protection with restrictions on redacting publicly available information.

The person investigating an incident cannot reasonably be expected to know which details of every construct used by a laboratory have been published. A published paper may describe a vector system while the particular construct, modification, or application involved in the incident remains unpublished. This creates a practical risk of inadvertently exposing intellectual property when preparing a public report. Public availability of related research should not be treated as establishing that every experimental detail is public.

Please distinguish information necessary for biosafety oversight from information necessary for public understanding, and allow sufficient time for investigator and appropriate institutional review before publication. Significant events should have useful public summaries explaining consequences, response, corrective actions, and follow-up while protecting unnecessary identifying or proprietary details.

Meeting minutes and publication timing

I support a firm deadline for approving and posting minutes. However, tying approval to the next convened meeting makes the available preparation and verification time depend on the committee's meeting schedule. This is particularly consequential for institutions with frequent IBC meetings.

I recommend an outer deadline of 90 days after the meeting for approval and public posting, with prompt publication once approval and permitted redactions are complete. This would preserve a definite, enforceable deadline while allowing reasonable time to verify an accurate record. Essential

safety decisions, conditions, and corrective actions should be communicated and implemented without waiting for minutes to be finalized.

Please illustrate sufficient minutes for a routine delegated approval, a complex committee review, and a locally reviewed incident. Show how minutes can reference established controls while recording project-specific reasoning and conditions.

Equivalent formats

Please expressly allow electronically generated documents preserving all required information, clear labels, and readability, without requiring the supplied file or table layout. Re-entering information into a separate document creates transcription risks and makes consistent records harder to maintain.

OSHA's acceptance of equivalent recordkeeping forms offers a useful precedent for defining required content while allowing different production methods. Comparable flexibility would support accurate, accessible reports and minutes.

6. Other feedback relevant to this resource: I appreciate NIH's recognition that implementation resources will be needed. Speaking for myself, I want to make this transition successful, and I believe that aim is widely shared among biosafety professionals. The staff revising policies, configuring systems, and training users must also maintain current oversight. Transition work requires staff time before any efficiencies from the new framework become available.

The extent of the proposed changes makes adequate time, clear expectations, and practical guidance particularly important to a successful transition.

Phased implementation

Please establish phased deadlines with distinct milestones for assurances, new submissions, existing approvals, reporting, and public posting. The transition period should begin after essential final guidance, templates, and assurance instructions are available. Allow supported pilot testing before requiring institution-wide implementation.

Publishing these materials with a defined schedule would let institutions organize staffing, systems, and training around stable requirements. Rushed or repeated conversion work can divert experienced staff from the ongoing oversight the policy is intended to strengthen.

Existing assessments and approvals

I am proud of the rigorous risk assessments and sound biosafety decisions made by the committees I work with. I want the transition process to preserve that work while addressing the new requirements.

Please provide an explicit process for carrying forward valid experimental descriptions, hazard assessments, and control decisions. Institutions should be able to map existing research to the new review route, assess newly applicable requirements, and update missing information without

reconstructing prior work.

Please allow previously approved research to transition at its next scheduled renewal, unless a material change or newly identified risk warrants earlier review. With a defined final conversion deadline, institutions could bring existing approvals into the new framework over one renewal cycle rather than reassess all ongoing work at once. Separate instructions should address newly covered research and institution-wide requirements during that period.

The process should specify what may be retained, what requires reconsideration, who may approve the transition, and when fresh review is necessary. Retaining an assessment should not automatically extend approval or waive a newly applicable requirement.

Please also explain the treatment of pending submissions, amendments, and renewals. Provide a continuity mechanism for institutions that submit complete assurances on time and maintain applicable safeguards while awaiting NIH action, so research is not interrupted solely by a processing queue.

Worked examples and continuing guidance

Please publish a substantial, searchable collection of examples covering ordinary cell and vector research, human materials administered to animals, clinical products, purified toxins, administrative updates, renewals, and incidents. Paired examples should identify the facts that change applicability, review route, containment, or reporting.

Include sufficient examples of investigator assessments, independent reviews, delegated decisions, and records incorporating institutional procedures by reference. Explain what investigators must contribute and what qualified biosafety staff may help prepare.

Biosafety Assurance

Getting the Biosafety Assurance right the first time will be an immediate priority for me. The more clearly NIH can describe what a complete and acceptable submission looks like, the better prepared I will be to do my part.

Please provide a submission checklist, a template or annotated outline, completed examples, and the criteria used to assess completeness and approve an assurance. Explain the expected level of detail, what supporting evidence must be submitted, and when links to existing policies and procedures are sufficient.

Please also explain how institutions with multiple IBCs should organize their submissions, how approved transition arrangements should be reflected, how deficiencies will be communicated and corrected, and which changes require an assurance update. Expected review timelines and a clear route for implementation questions would help institutions prepare successfully the first time.

Finally, please provide further public review of material policy revisions and essential implementation

resources before compliance is required.

My highest priority is to do my part in implementing this policy effectively. Clear expectations and practical resources would help me—and others responsible for this work—make the transition accurately, consistently, and with continued attention to protecting people and the environment. I would greatly appreciate any resources NIH can provide to support that effort.

Description: Document is a duplicate of what was put into the boxes, but in PDF form.

Personal Comments on the Draft NIH Biosafety Policy

Response to NOT-OD-26-112
October 19, 2026

1 Scope definitions and gaps in oversight

I am submitting these comments in my personal capacity as a biosafety professional. The views expressed are my own and do not represent my employer or any Institutional Biosafety Committee on which I serve. This statement applies to the entire submission.

I appreciate NIH's effort to address biosafety across biomedical research. Broader coverage can help institutions consider hazards beyond recombinant and synthetic nucleic acids. To apply that coverage consistently, institutions need clear criteria for deciding which activities fall within the policy.

Scope

Please explain how the threshold of known or potential risk to human health limits the listed material categories. Applying that threshold to routine research can be less straightforward than identifying the hazards of work involving a known pathogen.

Consider an experiment introducing a low-risk reporter into a well-characterized cell line by electroporation or nucleofection, without an infectious delivery vector. The absence of a viral vector does not resolve every hazard question, but it makes the basis for identifying human-health risk important.

Would this activity be covered because the cells are genetically modified, or must there also be an identifiable basis for known or potential harm? What information supports that determination? Such work can reasonably fall within an institution's biosafety program, but that does not resolve whether federal review requirements apply. Without a clear rule, equivalent work could be excluded at one institution and require approval at another.

Definitions and review categories

Please explain which characteristics distinguish primary materials from well-characterized cell lines for oversight purposes. Compare recently collected human cells, primary cells expanded in culture, and an established line carrying a low-risk reporter. Which facts change applicability, review route, or precautions? These are separate decisions, and a designation such as "established" may not answer all three.

Guidance should explain how to make these decisions when infectious status is uncertain. A sample known to contain HCV presents an identifiable agent-specific hazard. Cells from an apparently healthy donor, or an established line without relevant testing, present different questions about possible adventitious agents. What information is sufficient, and when is additional characterization or testing expected?

My primary concern is the feasibility of making sound decisions in the face of uncertainty, rather than whether the requirements err on the side of caution or permissiveness. If additional testing or characterization is expected, please make clear when and why, and what information is sufficient to reach a decision.

Please also provide practical criteria for applying the definitions of genetic modification and disease-causing self-propagating proteins. For proteins, the definition identifies a hazardous property, but institutions need to know how to evaluate preparations whose capacity for self-propagation or disease is uncertain. Routine protein expression should not require a speculative assessment of whether every expressed sequence could produce a hazardous misfolded protein. Examples and practical screening criteria would help identify preparations warranting closer review.

Gaps in oversight

Researchers have different levels of biosafety expertise and differing risk tolerance. They may describe work as harmless because hazards are low, protective measures are effective, or relevant risks are unfamiliar. Those explanations have different implications.

Please permit institutions to apply defined screening criteria and escalate consequential uncertainty, rather than rely solely on investigator self-classification. Routine activities should not each require a separate formal determination merely to establish that they are outside scope.

Other federal oversight

Please reconcile the provision allowing research to proceed under another federal agency's oversight with the clinical-review requirements. Specify which NIH-policy obligations remain after the other agency's applicable approvals or clearances have been obtained.

My concern here is clarity about the requirement itself. As written, I cannot confidently determine what remains required, and I would greatly appreciate an explicit explanation. A worked clinical example would be particularly helpful.

2 Tiered oversight and calibration to risk

I welcome the use of different review tiers. A simpler route for lower-risk work can direct more attention toward activities with greater uncertainty or consequences. The assessment and documentation requirements should preserve that benefit throughout the process.

Proportionate assessment

Please state expressly that a comprehensive assessment considers all relevant hazards, with the depth of analysis and documentation appropriate to the work. A complete assessment of a simple activity may be brief, even when another activity in the same review tier requires substantial analysis. Examples should demonstrate sufficient assessment without equating thoroughness with document length.

Administrative updates and minimal risk activities

Section III-B links amendment approval to changes that may affect the original biosafety assessment. Please confirm that authorized staff may record updates without that effect, such as a change in an administrative contact, without delegated scientific approval.

I also recommend a screening or registration pathway for defined minimal-risk activities without individual IBC approval. Institutions should establish criteria and responsible personnel, with reconsideration when relevant facts change. Delegation alone can save committee time while leaving most staff work intact or increasing administrative requirements.

Established controls

Please expressly permit assessments to incorporate approved institutional procedures by reference. The record should identify the work, explain why the controls apply, and describe departures or additional precautions. Project-specific factors and decisions should receive the emphasis.

Explicit permission would help institutions confidently use this approach rather than reproduce standard procedures in every assessment.

Incident reporting and disclosure

These are my greatest concerns. Effective accountability depends on reliable information and prompt, candid reporting. I am concerned that requiring full investigations and public reports for covered minor incidents and isolated administrative errors could make the process appear punitive, discourage reporting and cooperation, and erode the trust that a strong safety culture requires. The policy should establish when a full investigation is warranted and when a simpler review and response are sufficient.

Requirements should distinguish administrative noncompliance from exposures or releases with material safety consequences. The required investigation, documentation, and corrective action should reflect the event's significance. Repeated lapses, uncertain controls, or unreviewed changes warrant closer attention, but an isolated administrative lapse should not automatically require the same response as a serious containment failure.

Please separate detailed oversight records from public accounts. Significant events should receive timely public summaries explaining what happened, actual or potential consequences, the response, corrective actions, and follow-up. Defined minor events should be eligible for concise or grouped accounts, with fuller records retained for oversight and inspection.

OSHA's distinction between detailed injury records and its Form 300A workplace summary offers a useful design analogy. The aim is meaningful accountability with appropriate protection for affected people. If detailed public reports remain required, specify proportionate content for different event categories and protect against identification through combined details.

3 Risk Groups and Biosafety Levels

Risk Groups provide a useful starting point for understanding agent hazards, while Biosafety Levels describe precautions for particular activities. Preserving that distinction supports sound assessment without requiring institutions to assign an agent classification to every biological material.

Please address a common situation: mice are administered human cells, no specific infectious agent is known to be present, and bloodborne-pathogen precautions are used because infectious status is uncertain. A qualified reviewer subsequently evaluates documented characterization or testing that supports reduced precautions for the material.

Would selecting lower containment for subsequent animal housing require full-committee review under the provisions for lowering containment of RG2 agents, even though the initial precautions address uncertain infectious status rather than an identified agent, or could the decision receive delegated review? Would the answer differ if the housing conditions were established during the original approval rather than proposed later as an amendment?

The initial precautions address possible contamination; they do not establish that an RG2 agent is present. Conversely, negative test results do not establish absence of every possible pathogen or automatically justify lower animal containment. Please explain what evidence and documentation are sufficient to make this decision, while preserving professional judgment about relevant testing and remaining uncertainty.

OSHA's June 21, 1994 interpretation recognizes documented characterization of certain human cell cultures when determining Bloodborne Pathogens Standard coverage. Please explain how such evidence may inform the separate NIH assessment, without treating an occupational-safety determination as an automatic animal-containment decision.

A worked example should identify the appropriate review route and when full-committee or federal approval is required. Clear guidance would support consistent decisions without creating a universal testing panel or assigning a Risk Group solely because precautions were initially used.

4 Voluntary compliance

Making practical biosafety resources available beyond NIH-funded institutions is a useful part of this effort. Accessible training, technical consultation, assessment tools, and worked examples could provide clear benefits to organizations choosing to participate voluntarily.

I encourage NIH to develop these resources with their intended users and support staged adoption of useful practices. A voluntary incident-learning system could also help institutions share lessons and prevent recurrence. I would welcome a resource comparable to NIOSH, focused specifically on biosafety lessons and prevention.

Clear explanations of how confidentiality and de-identification operate, and how voluntary submissions are distinguished from mandatory reports, would help contributors understand the protections and responsibilities involved. Straightforward participation and visible benefits would support continued engagement.

5 Incident reporting and meeting minutes templates

Standard templates can improve consistency and make oversight easier to understand. Their instructions should show how sufficient information varies with the event or review and permit equivalent documents generated from existing systems.

Incident reporting

Please distinguish the information expected for initial notification, the completed investigation, and public accountability. Those purposes may require different levels of detail. Building on the template's distinction between initial and final reports, please specify what belongs in each stage and what must be included in the public account.

Requiring the same detailed account for different purposes can create unnecessary disclosure and administrative work without improving the information available for oversight.

Please provide completed examples for an administrative approval lapse, a minor event reviewed locally, and a serious exposure or release. Allowing "not applicable" is helpful, but institutions also need examples of sufficient analysis.

The current template does not appear well suited to administrative matters. For an overlooked renewal, what would constitute a sufficient root-cause analysis and corrective-action response? A completed example should demonstrate the expected depth of explanation and when a brief account is adequate. This would support useful corrective action without encouraging lengthy narratives that add little understanding.

Lower risk events and duplicate public records

The paragraph requiring local review of lower-risk events does not specify use of the incident template, while the later posting provision appears to require it broadly. The full template does not appear well suited to many of these events. Please clarify whether a full investigation and separate template-based public report are required for lower-risk events, and explain what information is actually needed.

I recommend allowing a concise account in publicly posted minutes to satisfy the public-record requirement for defined lower-risk events, without a separate full-template report. Specify the necessary information, including the event's significance, the IBC's review, the response, and preventive action. This would preserve accountability while avoiding duplicate public documents describing the same review.

Please also permit periodic grouped summaries, such as quarterly summaries, for defined recurring minor events where individual narratives add little information. These could complement the minutes, using a summary approach analogous to OSHA Form 300A. Detailed institutional records should remain available for oversight and inspection, with the same privacy protections applied regardless of the public format.

Privacy and unpublished information

I appreciate the permission to protect private and proprietary information. However, details already available elsewhere can identify an affected employee when combined with an incident narrative. A PI's identity, project description, role, date, and medical information may together reveal who was involved.

Please permit omission or generalization when the combination creates a meaningful identification risk, even if individual details are otherwise public. Instructions should reconcile this protection with restrictions on redacting publicly available information.

The person investigating an incident cannot reasonably be expected to know which details of every construct used by a laboratory have been published. A published paper may describe a vector system while the particular construct, modification, or application involved in the incident remains unpublished. This creates a practical risk of inadvertently exposing intellectual property when preparing a public report. Public availability of related research should not be treated as establishing that every experimental detail is public.

Please distinguish information necessary for biosafety oversight from information necessary for public understanding, and allow sufficient time for investigator and appropriate institutional review before publication. Significant events should have useful public summaries explaining consequences, response, corrective actions, and follow-up while protecting unnecessary identifying or proprietary details.

Meeting minutes and publication timing

I support a firm deadline for approving and posting minutes. However, tying approval to the next convened meeting makes the available preparation and verification time depend on the committee's meeting schedule. This is particularly consequential for institutions with frequent IBC meetings.

I recommend an outer deadline of 90 days after the meeting for approval and public posting, with prompt publication once approval and permitted redactions are complete. This would preserve a definite, enforceable deadline while allowing reasonable time to verify an accurate record. Essential safety decisions, conditions, and corrective actions should be communicated and implemented without waiting for minutes to be finalized.

Please illustrate sufficient minutes for a routine delegated approval, a complex committee review, and a locally reviewed incident. Show how minutes can reference established controls while recording project-specific reasoning and conditions.

Equivalent formats

Please expressly allow electronically generated documents preserving all required information, clear labels, and readability, without requiring the supplied file or table layout. Re-entering information into a separate document creates transcription risks and makes consistent records harder to maintain.

OSHA's acceptance of equivalent recordkeeping forms offers a useful precedent for defining required content while allowing different production methods. Comparable flexibility would support accurate, accessible reports and minutes.

6 Implementation resources and additional guidance

I appreciate NIH's recognition that implementation resources will be needed. Speaking for myself, I want to make this transition successful, and I believe that aim is widely shared among biosafety professionals. The staff revising policies, configuring systems, and training users must also maintain current oversight. Transition work requires staff time before any efficiencies from the new framework become available.

The extent of the proposed changes makes adequate time, clear expectations, and practical guidance particularly important to a successful transition.

Phased implementation

Please establish phased deadlines with distinct milestones for assurances, new submissions, existing approvals, reporting, and public posting. The transition period should begin after essential final guidance, templates, and assurance instructions are available. Allow supported pilot testing before requiring institution-wide implementation.

Publishing these materials with a defined schedule would let institutions organize staffing, systems, and training around stable requirements. Rushed or repeated conversion work can divert experienced staff from the ongoing oversight the policy is intended to strengthen.

Existing assessments and approvals

I am proud of the rigorous risk assessments and sound biosafety decisions made by the committees I work with. I want the transition process to preserve that work while addressing the new requirements.

Please provide an explicit process for carrying forward valid experimental descriptions, hazard assessments, and control decisions. Institutions should be able to map existing research to the new review route, assess newly applicable requirements, and update missing information without reconstructing prior work.

Please allow previously approved research to transition at its next scheduled renewal, unless a material change or newly identified risk warrants earlier review. With a defined final conversion deadline, institutions could bring existing approvals into the new framework over one renewal cycle rather than reassess all ongoing work at once. Separate instructions should address newly covered research and institution-wide requirements during that period.

The process should specify what may be retained, what requires reconsideration, who may approve the transition, and when fresh review is necessary. Retaining an assessment should not automatically extend approval or waive a newly applicable requirement.

Please also explain the treatment of pending submissions, amendments, and renewals. Provide a continuity mechanism for institutions that submit complete assurances on time and maintain applicable safeguards while awaiting NIH action, so research is not interrupted solely by a processing queue.

Worked examples and continuing guidance

Please publish a substantial, searchable collection of examples covering ordinary cell and vector research, human materials administered to animals, clinical products, purified toxins, administrative updates, renewals, and incidents. Paired examples should identify the facts that change applicability, review route, containment, or reporting.

Include sufficient examples of investigator assessments, independent reviews, delegated decisions, and records incorporating institutional procedures by reference. Explain what investigators must contribute and what qualified biosafety staff may help prepare.

Biosafety Assurance

Getting the Biosafety Assurance right the first time will be an immediate priority for me. The more clearly NIH can describe what a complete and acceptable submission looks like, the better prepared I will be to do my part.

Please provide a submission checklist, a template or annotated outline, completed examples, and the criteria used to assess completeness and approve an assurance. Explain the expected level of detail, what supporting evidence must be submitted, and when links to existing policies and procedures are sufficient.

Please also explain how institutions with multiple IBCs should organize their submissions, how approved transition arrangements should be reflected, how deficiencies will be communicated and corrected, and which changes require an assurance update. Expected review timelines and a clear route for implementation questions would help institutions prepare successfully the first time.

Finally, please provide further public review of material policy revisions and essential implementation resources before compliance is required.

My highest priority is to do my part in implementing this policy effectively. Clear expectations and practical resources would help me—and others responsible for this work—make the transition accurately, consistently, and with continued attention to protecting people and the environment. I would greatly appreciate any resources NIH can provide to support that effort.

465. Michael S. Rogers

I am responding: On behalf of myself

Name: Michael S. Rogers

Name of Organization:

Type of Organization: Academic Institution

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Work on drug discovery, including for cancer, endometriosis, blindness.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed scope risks encompassing many technologies with long and well-established records of safe use, including replication-deficient lentiviral vectors, routine expression of non-oncogenic transgenes and fluorescent protein fusions, and many common CRISPR-based genome-engineering applications. While appropriate biosafety practices should remain in place, decades of experience suggest that these technologies present fundamentally different risks than novel pathogens, gene drives, or engineered organisms intended for or at risk of environmental release. The final policy should more clearly distinguish mature technologies with extensive safety records from activities that present credible public-health or environmental risks. Failure to do so may substantially expand oversight without corresponding improvements in biosafety.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Oversight should be proportional to demonstrated risk. For laboratories conducting relatively low-risk molecular and cellular research, modernization should ideally decrease administrative burden while improving oversight of genuinely higher-risk activities. Several provisions of the draft appear likely to expand documentation, reporting, and review requirements without a clear demonstration of corresponding safety benefits.

In addition, oversight systems naturally tend toward increasingly conservative interpretations over time. The consequences of under-regulation are highly visible, whereas the costs of excessive regulation are diffuse and rarely measured. Without explicit mechanisms that periodically streamline oversight for mature technologies with strong safety records, administrative burden is likely to grow continuously even when biosafety outcomes do not improve.

I encourage NIH to incorporate objective criteria allowing low-risk, well-established technologies to move into simplified oversight pathways as safety experience accumulates.

3. Continued utility of Risk Groups: Whatever framework NIH adopts, risk assessment should be driven by actual hazard rather than the mere presence of genetic modification. In many cases, genetic modifications substantially reduce risk rather than increase it. A risk assessment system should avoid

creating incentives to treat all genetically modified organisms as inherently higher risk than their parental counterparts. A flexible, evidence-based approach that considers the characteristics of the final agent is preferable to categorical approaches based solely on the use of genetic engineering technologies.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Any mechanisms promoting voluntary compliance should emphasize practical biosafety guidance, training, and dissemination of best practices rather than additional administrative requirements. The strong safety record of U.S. biomedical research is due in large part to professional norms, training, and an established culture of safety. Policies that strengthen those factors are likely to be more effective than policies focused primarily on additional documentation or reporting requirements.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I am concerned by the proposed public disclosure requirements associated with incident reports and meeting minutes. Transparency is important, but transparency should not be confused with public dissemination of detailed operational information. Biosafety discussions often include technical descriptions of containment practices, incident analyses, vulnerabilities, and research procedures.

Excessive disclosure may discourage candid committee deliberations and could provide useful information to individuals or organizations operating outside the strong biosafety culture and accountability systems that characterize leading U.S. research institutions. NIH should consider public summaries of committee actions and incident outcomes rather than requiring disclosure of detailed deliberative material.

6. Other feedback relevant to this resource: The United States has developed a strong biosafety record through a combination of appropriate oversight, extensive training, institutional accountability, and a deeply ingrained culture of safety. As NIH finalizes this policy, it should consider the impact of new requirements on scientific productivity and international competitiveness.

Biomedical research is increasingly global. If low-risk research becomes subject to substantially greater administrative burden without measurable safety gains, innovation may simply shift to jurisdictions with less burdensome oversight. This concern is particularly relevant for rapidly evolving fields such as genome engineering and synthetic biology.

The ultimate goal should be to increase biosafety while reducing unnecessary burden on investigators conducting low-risk research. Success should be measured by demonstrable improvements in biosafety outcomes rather than increases in the number of protocols reviewed, forms completed, or reports generated.

466. ASM

I am responding: On behalf of an organization

Name: Nicole Zimmerman

Name of Organization: ASM

Type of Organization: Professional Organization/Association

Role: Other

Role - Other: Policy Staff

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): microbiology, infectious diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: While understanding that NIH has excluded plant pathogens from the proposed policy because of NIH's focus on human health, ASM members raised concerns that excluding plant pathogen research from NIH oversight could expose the nation's food supply to new risks. ASM requests that NIH work with USDA and other research agencies to ensure oversight over plant pathogen research is sufficient and ensure that the plant pathogen research oversight policies are complementary and not contradictory with oversight of other kinds of pathogen research.

Furthermore, ASM members requested clarification of several of the definitions in the proposed biosafety policy:
• The definition of "toxin" in the policy – "a protein or peptide produced by living organisms that causes harm in humans" -- is broad and could be interpreted to include allergens that humans experience in everyday life, like pollen.
• The policy covers "cells or organisms, other than plants, containing [infectious agents or prions]." However, all higher-level eukaryotic cells contain endogenous retroviruses. ASM members requested clarification that the policy covers cells that are infected whether lytically, latently or persistently.
• The definition of "wild type" and "novel agent or organism" could be subject to differing interpretations of what organisms, cell and viruses are naturally occurring or are considered genetically modified.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): ASM members welcomed the provision allowing IBC-delegated member review for certain classes of experiments and urged NIH to retain this provision in the final policy. However, ASM members also expressed concerns that the removal of exemptions for low-risk work and biosafety level 1 (BSL-1) transgenic animals will increase the IBC's workload and reduce the amount of time that the IBC is able to spend reviewing higher-risk experiments. ASM members also raised that including experiments involving transient transfection of plasmid expression vectors in the scope of the policy could create increased workloads

for IBCs and investigators.
The draft policy requires that research involving novel or emerging biological agents (i.e agents that are not yet included in a Risk Group classification or the BMBL) must be reviewed and approved by both NIH and local IBCs. ASM members flagged that the requirement for NIH review could slow down research to understand emerging and novel pathogens and to develop medical countermeasures for these pathogens.

3. Continued utility of Risk Groups: Overall, ASM members appreciated that the scope of the draft policy is based on risk rather than a specific technology (i.e. research with recombinant or synthetic nucleic acid molecules). ASM members appreciated the inclusion of Risk Groups in the policy, affirming that Risk Groups are useful as a baseline for risk assessment and provide needed flexibility for institutions.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): ASM members raised that the requirement to post unredacted incident reports on a public-facing website, regardless of whether the incident merited reporting to NIH, could dissuade researchers from reporting near misses or other low-risk incidents to institutional officials and that this requirement could ultimately harm efforts to protect biosafety. The members' concern is that when researchers do not report low-risk incidents, this prevents IBCs and biosafety staff from proactively identifying areas where new or updated Standard Operating Procedures or improved training are needed. ASM members requested that NIH remove this requirement from the final policy and that NIH allow institutions to post redacted incident reports publicly.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The draft policy provides requirements and considerations for risk assessment for synthetic biological agents, and the references to synthetic biology in the policy are focused on infectious agents. ASM members noted that there are other uses for synthetic biology that do not involve infectious agents, such as the production of chemicals and peptides by bacteria and requested further clarification from NIH that the policy does not include these lower-risk activities.
The policy includes specific examples of experiments involving the influenza virus which must be conducted at a BSL-3. ASM members noted that influenza viruses do not represent the whole virology field, and NIH should consider other classes of viruses that may require use-case examples.

Dr. Lyric Jorgenson
Director
NIH Office of Science Policy
9000 Rockville Pike
Bethesda, MD 20892

Re: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Dr. Jorgenson,
Thank you for the opportunity to respond to the Draft NIH Biosafety Policy Involving Biohazards. ASM is one of the oldest and largest life science societies with over 38,000 members in the U.S. and around the world, with many ASM members conducting research covered by NIH biosafety policies.

In response to NIH's call for feedback on the Biosafety Modernization Initiative, ASM convened a group of experts in biosafety and biosecurity who have decades of experience conducting research conducted by the policy, including research that may be considered high risk, and members with experience overseeing institutional biosafety programs and policies. This letter documents their feedback on the topics requested by NIH and additional areas for consideration.

General concerns
This policy is open to public comment at the same time as agencies are working to implement the US Government Policy for Stopping High Risk Life Sciences Research.[1] ASM members are concerned that requirements of the US Government Policy for Stopping High Risk Life Sciences Research will increase the workload of PIs, institutional biosafety staff and IBCs significantly. This feedback aligns with broader concerns regarding administrative burden. ASM members raised concerns that the draft NIH Biosafety Policy for Research Involving Biohazards will require increased administrative efforts to comply with the policy and requested that NIH ensure that the final NIH biosafety policy and the US Government Policy for Stopping High Risk Life Sciences

[1] United States Government Policy for Stopping High Risk Life Sciences Research. 2026. https://www.whitehouse.gov/wp-content/uploads/2026/07/USG-Policy-for-Stopping-High-Risk-Life-Sciences-Research_July-2026.pdf

1752 N St. NW
Washington, DC 20036
asm.org

Research are aligned and do not add additional undue administrative burden for PIs and institutions. ASM acknowledges that NIH is currently soliciting feedback from the scientific community about reducing administrative burden associated with obtaining, maintaining and reporting on NIH extramural research funding, and encourages NIH to consider the impact of these proposed policies on administrative burden

In the September 2025 announcement for the Biosafety Modernization Initiative, NIH said that the initiative will provide an opportunity for institutional leadership to reassess whether their Institutional Biosafety Committees (IBCs) are receiving support and resources equal to other institutional committees, such as those that review human subjects research and the care and use of animals.[2] Institutional Animal Care and Use Committees and Institutional Review Boards often have more staff support and resources than IBCs at most institutions.[3] ASM requests that NIH work with institutions to ensure that IBCs have adequate resources to implement both the NIH biosafety policy and the US Government Policy for Stopping High Risk Research. ASM members also requested that NIH ensure that the requirements of both policies are complementary and do not create contradictory requirements.

Scope of Research Covered by the New Policy

While understanding that NIH has excluded plant pathogens from the proposed policy because of NIH's focus on human health, ASM members raised concerns that excluding plant pathogen research from NIH oversight could expose the nation's food supply to new risks. ASM requests that NIH work with USDA and other research agencies to ensure oversight over plant pathogen research is sufficient and ensure that the plant pathogen research oversight policies are complementary and not contradictory with oversight of other kinds of pathogen research.

Furthermore, ASM members requested clarification of several of the definitions in the proposed biosafety policy:

- The definition of "toxin" in the policy – "a protein or peptide produced by living organisms that causes harm in humans" -- is broad and could be interpreted to include allergens that humans experience in everyday life, like pollen.

[2] https://www.nih.gov/about-nih/nih-director/statements/nih-launches-initiative-modernize-strengthen-biosafety-oversight

[3] Johnson CM, Dobos KM. The Evolving Landscape of Institutional Biosafety Committees and Biosafety Programs: Results from a National Survey on Organizational Structure, Resources, and Practices. Appl Biosaf. 2019 Dec 1;24(4):213-219. doi: 10.1177/1535676019886175. Epub 2019 Dec 1. PMID: 36032060; PMCID: PMC9134475.

1752 N St. NW
Washington, DC 20036
asm.org

- The policy covers "cells or organisms, other than plants, containing [infectious agents or prions]." However, all higher-level eukaryotic cells contain endogenous retroviruses. ASM members requested clarification that the policy covers cells that are infected whether lytically, latently or persistently.
- The definition of "wild type" and "novel agent or organism" could be subject to differing interpretations of what organisms, cell and viruses are naturally occurring or are considered genetically modified.[4]

Structure of Tiered Oversight

ASM members welcomed the provision allowing IBC-delegated member review for certain classes of experiments and urged NIH to retain this provision in the final policy. However, ASM members also expressed concerns that the removal of exemptions for low-risk work and biosafety level 1 (BSL-1) transgenic animals will increase the IBC's workload and reduce the amount of time that the IBC is able to spend reviewing higher-risk experiments. ASM members also raised that including experiments involving transient transfection of plasmid expression vectors in the scope of the policy could create increased workloads for IBCs and investigators. The draft policy requires that research involving novel or emerging biological agents (i.e agents that are not yet included in a Risk Group classification or the BMBL) must be reviewed and approved by both NIH and local IBCs. ASM members flagged that the requirement for NIH review could slow down research to understand emerging and novel pathogens and to develop medical countermeasures for these pathogens.

Continued utility of Risk Groups

Overall, ASM members appreciated that the scope of the draft policy is based on risk rather than a specific technology (i.e. research with recombinant or synthetic nucleic acid molecules). ASM members appreciated the inclusion of Risk Groups in the policy, affirming that Risk Groups are useful as a baseline for risk assessment and provide needed flexibility for institutions.

Effectiveness of compliance and enforcement mechanisms

ASM members raised that the requirement to post unredacted incident reports on a public-facing website, regardless of whether the incident merited reporting to NIH, could dissuade researchers from reporting near misses or other low-risk incidents to institutional officials and

that this requirement could ultimately harm efforts to protect biosafety. The members' concern is that when researchers do not report low-risk incidents, this prevents IBCs and biosafety staff from proactively identifying areas where new or updated Standard Operating Procedures or improved training are needed. ASM members requested that NIH remove this requirement from the final policy and that NIH allow institutions to post redacted incident reports publicly.

Feedback on implementation resources

The draft policy provides requirements and considerations for risk assessment for synthetic biological agents, and the references to synthetic biology in the policy are focused on infectious agents. ASM members noted that there are other uses for synthetic biology that do not involve infectious agents, such as the production of chemicals and peptides by bacteria and requested further clarification from NIH that the policy does not include these lower-risk activities.

The policy includes specific examples of experiments involving the influenza virus which must be conducted at a BSL-3. ASM members noted that influenza viruses do not represent the whole virology field, and NIH should consider other classes of viruses that may require use-case examples.

Conclusion

ASM appreciates the opportunity to provide feedback on the NIH Biosafety Policy for Research Involving Biohazards and appreciates NIH's efforts to broadly engage the scientific community in updating its biosafety policy. If you have any questions or would like to further discuss these comments, please contact Nicole Zimmerman, Senior Federal Affairs Officer, at nzimmerman@asmusa.org.

Thank you,

Amalia Corby
Director of Federal Affairs

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Government Agency

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious diseases

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Note - Unless otherwise indicated, for sections 1-6 the page numbers refer to the page numbers of the pdf generated when the draft policy is saved as a pdf.

a) “Well characterized cell lines” (Pg 10, Section IV-3) by themselves may not necessarily fall within any of the categories described under the scope of this policy - i.e. cell lines such as PC-12 (rat, ATCC), BHK-21 (hamster, ATCC) do not have agents that are known to cause disease in healthy humans. It may be appropriate to exempt work involving primary or immortalized non-recombinant cells lines that do not cause disease in healthy humans.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): a) Having a mechanism to exempt low-risk research may be appropriate (i.e. use of well-characterized cell lines, recombinant derivatives of low-risk pathogens that are not capable of replication or infection, research covered under III-F of the current NIH guidelines etc.). Having the PIs submit once to the IBC or its designated subcommittee for an official exempt determination may be sufficient for tracking, transparency, and accountability purposes. It may be appropriate to require a new submission if there is a change to the risk or containment requirements involved in the research. Periodic reviews post-approval maybe appropriate, but some low-risk research may not need the same level of oversight as higher risk research.

b) Since the Federal Select Agent Program (FSAP) already oversees the use of biological select agents and toxins (Pg 12, https://www.selectagents.gov/) having the IBC oversee them as well may be a duplication of review efforts and perhaps inappropriate as described below.

b.i) Under the FSAP, the CDC and USDA already review research involving non recombinant biological select agents and toxins. This review requires specialized expertise and follows stringent reporting mandates. Wouldn’t it be appropriate to defer to the FSAP review for select agent research rather than mandate that the IBC provide a duplicate review? This would be similar to deferring to FDA for some

research.

b.ii) What action should the investigator take if the recommended actions provided under the FSAP and IBC are not in agreement? Does the recommendations of one authority take precedence over the other? If so, isn't it appropriate to defer to the superseding authority in the first place?

b.iii) It may be appropriate to have the IBC oversee some work involving recombinant biological select agents and toxins as that is currently already being done. However, a duplication of review efforts can be prevented and clarity of guidance for PI can be maintained if the same type of research is not reviewed by both the IBC and under the FSAP.

c) Under incident reporting (Pg 7) states "Any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approval" requires immediate notification to NIH within 24 hours and a full incident report within 30 days.

c.i) If "failure to maintain approval" refers to failure to comply with the safety regulations outlined in the IBC approval for research involving an infectious agent especially an agent considered to be RG 3 or 4 it may be appropriate to notify the NIH immediately and provide a full incident report.

c.ii) The verbiage "failure to maintain approval" if applicable to annual reviews it would imply that even a delay of two days for approving an annual review for low-risk research (i.e. work involving non-infectious, non-viable agents) would trigger an incident that requires immediate notification to NIH. Considering the low risk of the research, isn't it more appropriate to record such an incident as a relatively less urgent issue? If this was not the intent of this statement then it would be helpful if the language was clearer.

3. Continued utility of Risk Groups: None.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): None.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: a) Per the draft NIH policy all incident reports should be published on a public facing website. There is no dispute that all incidents should be recorded and maintained as a part of the institutional record and perhaps periodically submitted to NIH as individual or aggregate records. However, it would seem that publishing all minor events on the public facing website retracts from any benefit that public records would serve as explained below.

a.i) Publishing a breach of containment of an infectious agent or an incident where an infected person required medical care in a hospital may be beneficial for the public. Conversely, knowing how many needlesticks from a saline syringe occurred in a lab does not create a safety concern for the public. However, when both of these incidents are lumped together, then the important incidents get buried under too much data. I understand they will be recorded as separate incidents. But every additional record only adds to the volume of information requiring the public to sift through lots of data to find anything meaningful to them. In my opinion, if publication is necessary, it would be beneficial to publish only incidents that may potentially compromise the safety of the community. All other incident reports

should be maintained as a part of the institutional and/or NIH record and can be available upon request in compliance with Freedom of Information Act (FOIA). Publishing aggregate incidents for minor incidents may be a more meaningful alternative to publishing individual minor incidents.

a.ii) Indiscriminately publishing all incidents online creates a huge administrative burden with little benefit to the public.

a.iii) The general public may not always be able to interpret the significance of a lab incident in terms of its harm to the surrounding community and environment. Even minor incidents may be perceived as disproportionally harmful and may contribute to public unrest and fear. I.e. some select agent work can be safely conducted at BSL 2 with the necessary safety precautions in place. However, while an individual with expertise may be able to distinguish the difference between low-risk work and high-risk work, an individual without the necessary expertise may perceive the risk posed by a non-infectious, non-viable select agent derivative the same risk as its infectious counterpart. Thus, leading to unnecessary public fear. This may be an unintended consequence of publishing incident reports in a public facing website. It may be advisable to have a qualified individual/s review incident reports rather than open every minor infraction up for public comment.

a.iv) It would be helpful to understand the benefit of publishing all meeting minutes and incident reports on a public facing website. The IACUC and IRB do not publish any of those documents in a public website by default although they too are subject to FOIA.

6. Other feedback relevant to this resource: a. In Section III (pg. 5) policy states “Assurances are approved by NIH for a period of up to four years.”. Verbiage should be clarified as to whether Assurances are approved for 4 years or if NIH may choose to approve it for fewer years under certain circumstances.

b. Under IBC functions (pg. 6) the policy state that “No member of the IBC may be involved in the review or approval of a project in which they are or expect to be engaged, or in which they have a direct financial or any other conflict of interest, except to provide information requested by the IBC to facilitate their review. Such members can be counted for purposes of establishing a voting quorum for the meeting even if they recuse themselves from the final determination related to the project.”. The verbiage is unclear. How can recusing members be meaningfully counted for a “voting quorum” if they don’t contribute to the vote?

c. Under Section IV-1 and IV-2, “Categories of Oversight for Research Based on Risk” (pg. 9-11) the same criteria are repeated in multiple categories. Therefore, the criteria applicable to each section should be clarified. See (i) and (ii) below,

c.i) Section IV-1: “Initial requests for NIH to lower containment for research involving wild type or genetically modified RG3 or RG4 biological agents (e.g., experiments with attenuated or replication-defective constructs).” AND
c.ii) Section IV-2: “Research involving RG3 or RG4 wild-type biological agents.”

d) Section IV-2 (pg. 10) states that “Research with primary cells that may be contaminated by adventitious agents.”. If a researcher, not associated with an FDA approved study, wanted to use

specimens such as blood or sputum from human participants that are, for example, vaccinated with a live-attenuated virus (i.e. MMR, FluMist), do they need IBC oversight?

Uploaded File: Draft-NIH-Biosafety-Policy-2026_Individual-Comments.pdf

Description: Attached is the word document with the same comments as above.

Comments on Draft NIH Biosafety Policy for Research Involving Biohazards (Aug 2026)

Unless otherwise indicated, for sections 1-6 the page numbers refer to the page numbers of the pdf generated when the draft policy is saved as a pdf.

1. **Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed.**

    a. "Well characterized cell lines" (Pg 10, Section IV-3) by themselves may not necessarily fall within any of the categories described under the scope of this policy - i.e. cell lines such as PC-12 (rat, ATCC), BHK-21 (hamster, ATCC) do not have agents that are known to cause disease in healthy humans. It may be appropriate to exempt work involving primary or immortalized non-recombinant cells lines that do not cause disease in healthy humans.

2. **Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local).**

    a. Having a mechanism to exempt low-risk research may be appropriate (i.e. use of well-characterized cell lines, recombinant derivatives of low-risk pathogens that are not capable of replication or infection, research covered under III-F of the current NIH guidelines etc.). Having the PIs submit once to the IBC or its designated subcommittee for an official exempt determination may be sufficient for tracking, transparency, and accountability purposes. It may be appropriate to require a new submission if there is a change to the risk or containment requirements involved in the research. Periodic reviews post-approval maybe appropriate, but some low-risk research may not need the same level of oversight as higher risk research.

    b. Since the Federal Select Agent Program (FSAP) already oversees the use of biological select agents and toxins (Pg 12, https://www.selectagents.gov/) having the IBC oversee them as well may be a duplication of review efforts and perhaps inappropriate as described below.

        i. Under the FSAP, the CDC and USDA already review research involving non-recombinant biological select agents and toxins. This review requires specialized expertise and follows stringent reporting mandates. Wouldn't it be appropriate to defer to the FSAP review for select agent research rather than mandate that the IBC provide a duplicate review? This would be similar to deferring to FDA for some research.

        ii. What action should the investigator take if the recommended actions provided under the FSAP and IBC are not in agreement? Does the recommendations of one authority take precedence over the other? If so, isn't it appropriate to defer to the superseding authority in the first place?

        iii. It may be appropriate to have the IBC oversee some work involving recombinant biological select agents and toxins as that is currently already being done. However, a duplication of review efforts can be prevented and clarity of guidance for PI can

be maintained if the same type of research is not reviewed by both the IBC and under the FSAP.

c. Under incident reporting (Pg 7) states "Any compliance violations at any BSL/ABSL, such as failure to obtain or maintain IBC approval" requires immediate notification to NIH within 24 hours and a full incident report within 30 days.

   i. If "failure to maintain approval" refers to failure to comply with the safety regulations outlined in the IBC approval for research involving an infectious agent especially an agent considered to be RG 3 or 4 it may be appropriate to notify the NIH immediately and provide a full incident report.

   ii. The verbiage "failure to maintain approval" if applicable to annual reviews it would imply that even a delay of two days for approving an annual review for low-risk research (i.e. work involving non-infectious, non-viable agents) would trigger an incident that requires immediate notification to NIH. Considering the low risk of the research, isn't it more appropriate to record such an incident as a relatively less urgent issue? If this was not the intent of this statement then it would be helpful if the language was clearer.

3. Continued utility of Risk Groups (RGs) as a baseline for risk assessment, particularly when agents are being genetically modified, versus use of Biosafety Levels (BSL) outlined in the Biosafety in Microbiological and Biomedical Laboratories (BMBL).

None.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions)

None.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates

a. Per the draft NIH policy all incident reports should be published on a public facing website. There is no dispute that all incidents should be recorded and maintained as a part of the institutional record and perhaps periodically submitted to NIH as individual or aggregate records. However, it would seem that publishing all minor events on the public facing website retracts from any benefit that public records would serve as explained below.

   i. Publishing a breach of containment of an infectious agent or an incident where an infected person required medical care in a hospital may be beneficial for the public. Conversely, knowing how many needlesticks from a saline syringe occurred in a lab does not create a safety concern for the public. However, when both of these incidents are lumped together, then the important incidents get buried under too much data. I understand they will be recorded as separate incidents. But every additional record only adds to the volume of information requiring the public to sift through lots of data to find anything meaningful to them. In my opinion, if

publication is necessary, it would be beneficial to publish only incidents that may potentially compromise the safety of the community. All other incident reports should be maintained as a part of the institutional and/or NIH record and can be available upon request in compliance with Freedom of Information Act (FOIA). Publishing aggregate incidents for minor incidents may be a more meaningful alternative to publishing individual minor incidents.

ii. Indiscriminately publishing all incidents online creates a huge administrative burden with little benefit to the public.

iii. The general public may not always be able to interpret the significance of a lab incident in terms of its harm to the surrounding community and environment. Even minor incidents may be perceived as disproportionally harmful and may contribute to public unrest and fear. I.e. some select agent work can be safely conducted at BSL 2 with the necessary safety precautions in place. However, while an individual with expertise may be able to distinguish the difference between low-risk work and high-risk work, an individual without the necessary expertise may perceive the risk posed by a non-infectious, non-viable select agent derivative the same risk as its infectious counterpart. Thus, leading to unnecessary public fear. This may be an unintended consequence of publishing incident reports in a public facing website. It may be advisable to have a qualified individual/s review incident reports rather than open every minor infraction up for public comment.

iv. It would be helpful to understand the benefit of publishing all meeting minutes and incident reports on a public facing website. The IACUC and IRB do not publish any of those documents in a public website by default although they too are subject to FOIA.

6. Feedback on the implementation resources and areas in which additional guidance would be beneficial.

a. In Section III (pg. 5) policy states "Assurances are approved by NIH for a period of up to four years.". Verbiage should be clarified as to whether Assurances are approved for 4 years or if NIH may choose to approve it for fewer years under certain circumstances.

b. Under IBC functions (pg. 6) the policy state that "*No member of the IBC may be involved in the review or approval of a project in which they are or expect to be engaged, or in which they have a direct financial or any other conflict of interest, except to provide information requested by the IBC to facilitate their review. Such members can be counted for purposes of establishing a voting quorum for the meeting even if they recuse themselves from the final determination related to the project.*". The verbiage is unclear. How can recusing members be meaningfully counted for a "voting quorum" if they don't contribute to the vote?

c. Under Section IV-1 and IV-2, "Categories of Oversight for Research Based on Risk" (pg. 9-11) the same criteria are repeated in multiple categories. Therefore, the criteria applicable to each section should be clarified. See (i) and (ii) below,

i. Section IV-1: “Initial requests for NIH to lower containment for research involving **wild type** or genetically modified **RG3 or RG4 biological agents** (e.g., experiments with attenuated or replication-defective constructs).” AND

ii. Section IV-2: “Research involving **RG3 or RG4 wild-type biological agents.**”

d. Section IV-2 (pg. 10) states that “*Research with primary cells that may be contaminated by adventitious agents.*”. If a researcher, not associated with an FDA approved study, wanted to use specimens such as blood or sputum from human participants that are, for example, vaccinated with a live-attenuated virus (i.e. MMR, FluMist), do they need IBC oversight?

Role: Other

Role - Other: Biosafety Professional

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of this policy is inconsistent and poorly defined.
Definitions need to be expanded and cover key terms like biohazard and laboratory research to ensure that the implementation of the policy can be executed, consistent, and enforceable. In addition to creating clarity expanding the definitions will create stronger internal consistency for the policy as a whole.
As it stands, this policy is solely focused on human health while the policy it supersedes covered activities conducted in animal facilities, greenhouses, agricultural settings, field studies, and other nonlaboratory environments where biological hazards are present. This creates a gap in scope that the policy should address whether by extending the scope or coordinating with other policies/ institutions.
The scope of biohazard is poorly defined and should be extended to cover more than just human pathogenicity.
The scope of laboratory needs to be better defined. As it stands it is unclear whether clinical sites and GMP facilities will be under this policy.
The exclusion of plants may create oversight gaps. Clarification is needed regarding how genetically modified plants, plant pathogens, plant-associated toxins, agricultural pests, and related organisms will be addressed. A comprehensive biosafety framework should reflect a One Health approach that considers human, animal, plant, and environmental health impacts.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A true risk based tiered oversight would allow for institutions to handle low risk activities and reserving federal reporting and review requirements for activities presenting the greatest potential risk, thus not overwhelming the system and creating flexibility in often complex situations.
The policy should delineate the process for a protocol renewal and that of a new protocol, accounting for risk and program changes.
Th policy should clarify what is reportable and what could be handled by the institution. A tiered approach to incident reporting would help focus federal oversight on significant events while reducing

administrative burden associated with minor incidents that do not involve exposure, environmental release, or significant risk.
The data shared in these reports should be deidentified and shared in a database or annual report so institutions can understand how they stack up nationally. This information can be used to generate research and better safety precautions, and for buy in at an institutional level to garner better risk protection overall.

3. Continued utility of Risk Groups: Risk groups are a good starting point, but do not adequately capture all risks associated with genetically modified organisms, novel constructs, etc. The final policy should preserve experiment-specific and site-specific risk assessments.
Additional guidance is needed regarding how institutions should determine risk groups under the proposed framework, particularly because the draft does not appear to identify whether information currently provided in Appendix B of the NIH Guidelines will still apply. BMBL does not include risk groups, and in some cases provides a BSL range. Clear guidance regarding the relationship between Risk Groups, project-specific risk assessment, and Biosafety Levels would improve consistency across institutions and in implementation of the policy.
Rigid attachment to universal minimum BSL-2 for GDMOs does not map well to arthropod, aquatic, greenhouse, ecological, or other specialized containment systems. Allowing institutional risk assessments to stand in for a strict adherence to mapped levels will create better safety and research overall.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The policy's expanded public posting requirements risk exposing proprietary research details, personal information, security-sensitive information, and context that may be misinterpreted. It is also likely to discourage prompt reporting of minor events and near misses, an important aspect of a strong safety culture. Some research areas are prone to security concerns for researchers involved, were identification, even generally, could put their personal safety at risk. NIH should require standardized public summaries that are de-identified and focused on oversight outcomes, corrective actions, and lessons learned, while detailed records remain available to NIH for oversight and through existing lawful disclosure processes.
A timeline for redaction and data retention should be outlined in the policy.
The policy should emphasize education and technical tools and model practices as voluntary feels like a misnomer in this case. Additionally, NIH should provide practical tools, templates, decision trees, training resources, and examples that can be implemented regardless of funding source to increase adoption.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The policy would benefit from clearer definitions, timelines, and specific reporting thresholds. Additional guidance is needed regarding whether incidents such as spills contained within primary containment, minor events without exposure or release, or needlesticks involving sterile needles require reporting at each BSL.
The new meeting minutes require significant administrative time investment, which is duplicative.
As previously mentioned, public posting of incident reports, especially as currently poorly defined, will discourage reporting and undermine hard won safety culture. Significant consideration should be given to de-identification standards, redaction requirements, aggregation of minor events, and protections for security-sensitive information.
This data should be aggregated in a searchable database to benefit safety nationwide, but only if it can be done so without violating researchers' work and right to privacy.

6. Other feedback relevant to this resource: This policy will require a great deal of work for institutions to implement. It requires revision of policies, new training, and a great deal more. Thus, phased implementation and implementation resources are required to minimize disruption of current research and ensure policy compliance.
The policy should allow for flexibility as scientific enterprises are rarely one-size fits all.
A glossary is needed with definitions that are clear through the whole policy.

Name of Organization:

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of research "conducted at or sponsored by the institution" needs precise definition. It is critical to clarify how this applies to non-NIH-funded research, affiliates, leased space, off-site collaborations, teaching, downstream clinical sites, and products originally developed with NIH funding.

The proposed six-month implementation timeline is insufficient and unrealistic for institutions to adequately comply, modify electronic systems, or revise local procedures. I recommend extending this to a minimum of 12 to 24 months and utilizing a phased, risk-based transition with established milestones that begin only after final guidance and required templates are made available.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Exempt activities must be clearly specified, or a framework for institutional discretion must be outlined. I request explicit identification of activities requiring no submission, documentation only, or prior approval, including the treatment of formerly exempt activities like the breeding of certain transgenic rodents or routine well-characterized cell lines. An exempt category section for lower-risk agents should be created to prevent unnecessary mandatory delegated IBC approval for minimal-risk activities.

3. Continued utility of Risk Groups: Risk Group (RG) describes agent characteristics and hazards, whereas Biosafety Level (BSL) describes containment conditions; these terms should not be treated as interchangeable. RGs should serve as a starting point for risk assessment, but they should not independently dictate review levels that conflict with a site-specific and experiment-specific risk assessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The current incident reporting requirements raise significant security and privacy concerns. Public posting of identified incident reports could expose proprietary research, personal medical information, and security-sensitive details, potentially discouraging a culture of prompt, voluntary near-miss reporting. I recommend

standardizing de-identified public summaries with clear redaction rules. Furthermore, the policy must clarify whether any event occurring in a BSL-3 or BSL-4 facility is reportable, regardless of whether it actually involves a biohazard or a credible biological exposure (e.g., minor spills or backup containment failures).

6. Other feedback relevant to this resource: To ensure national consistency and alleviate administrative burden, NIH should provide final, standardized templates for the Biosafety Assurance, risk assessments, meeting minutes, and incident reporting before the policy takes effect. We strongly recommend piloting these templates with diverse institutions and clearly distinguishing between required, conditional, and optional fields.

Institutions require clear decision trees or tables to determine the type of review (e.g., full committee, delegated, administrative, or NIH review) and to navigate incident reporting requirements. These tools should resolve overlapping categories, establish clear precedence rules between review pathways, and provide worked examples to guide institutional determinations.

The policy must align the expanded responsibilities of the BSO with explicit authority, independence, and institutional support. Minimum qualifications, institutional access, reporting relationships, and the authority to require corrective measures, escalate unresolved risks, and stop unsafe work must be clearly defined.

Clear expectations regarding occupational health are needed. The policy should include explicit triggers, assigned authorities, and distinct boundaries explaining how the Principal Investigator's (PI) responsibility for safe research interfaces with the institution's overall responsibility for developing, communicating, and providing occupational health services.

I request explicit rules mapping retention requirements to specific record types (e.g., protocols, risk assessments, delegated reviews, assurances, and meeting minutes). The policy should outline the triggering event, retention period, public availability period, and it should clarify requirements for non-NIH-funded work or records spanning multiple awards.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: We have prepared and submitted collated comments from our division as a whole, so those should be weighted significantly when reviewed. There are two points I wanted to personally comment on individually with the experience of being the Biosafety Officer at the NIH/Bethesda area for the last twenty years. Point (1) I applaud the OSP for encompassing the registrations of all potential pathogens in the new policy for Research Involving Biohazards- the NIH/Bethesda has been doing this since inception for over 50 years. In my experience registering investigators working with 'common' biological materials over the last two decades (human cells, cell lines, toxin, bacteria and viruses with work procedures approved at BSL-2)- I can share that for the vast majority of cases (over 90%), research activities with the material may not change for many years, and new procedures are not introduced that might change risk. With todays electronic registration systems, the registrations are a living document with annual reviews performed every year- keeping the registration up to date as opposed to a "snapshot in time". Admin changes (to personnel and laboratory) are made in real time, and any substantive changes that may introduce new risk can be submitted as a formal amendment and weighed by the IBC. Mandating a 3yr expiration period for all registrations simply because a date has passed is forcing regulatory constraints without safety benefit. The suggested time frame should be doubled to 6 years at least- to be less exhausting, or institutions should be able to decide their approach based on their systems, practices, research profile, and resources available to address realistic risks. Perhaps identifying a tiered approach for this deadline may be beneficial, with certain research activities of lower risk having longer permissible deadlines than other higher risk activities, or potentially risk introducing activities: such as when performing recombinant work in RG-3 and RG-4 organisms- where complete ('de novo') re-review of such research activities may be beneficial.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Regarding the tiered oversight approach as described in Section IV of the proposed policy, I am in favor with the OSP identifying lower risk activities that may be delegated to individuals or Subgroups of the IBC members. But in general there is new mandated oversight now described for the IBC to review all work with genetically modified organisms, and particularly also to have to review research with transgenic organisms that can be conducted safely at BSL-1/ABSL-1 that is newly required. This had previously been

removed successfully from the NIH Guidelines because it was determined (by OSP) that such oversight came with no safety benefit for the researchers. Research with established TG rodents and other species is quite commonplace and can be performed safely under established CORE and animal facility SOPs. Going back to this old requirement will be constraining not only to researchers but the entire review process. No estimation has been made to the additional resources it will take to comply with these requirements. It is apparent that regulatory efforts should be concentrated to where oversight will be most beneficial, and these new requirements as reintroduced in this proposed policy is in stark contrast to the stated goal of the policy "to expand the scope of the NIH Guidelines to all biohazards, while removing red tape for low-risk research". Once TG animals have been registered and found to be safe to work with, a requirement to register their use in subsequent experiments is red-tape and unnecessary "paperwork" from safety- which is a perception we work very hard to overcome- we do this by addressing realistic risks and making meaningful assessments to benefit research activities. Identifying oversight concerns in this regard would be most beneficial to understand why it would be newly required in the policy.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Re: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards; release date, August 19, 2026 (NOT-OD-26-112)

To the NIH Office of Science Policy:

Public Responsibility in Medicine and Research (PRIM&R), which has more than 3,200 active members throughout the research enterprise, appreciates the opportunity to respond to the NIH on this matter. PRIM&R is a nonprofit organization dedicated to advancing the highest ethical standards in the conduct of research. Since 1974, PRIM&R has served as a professional home and trusted thought leader for the research protections community. PRIM&R seeks to ensure that all stakeholders in the research enterprise appreciate the central importance of ethics to the advancement of science. Our perspective is informed by the experiences of professionals responsible for implementing federal research regulations across academic, healthcare, government, and independent research institutions.

NIH states that it is seeking public input on its "Draft NIH Biosafety Policy for Research Involving Biohazards, which, when finalized, will supersede the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules."[1]

According to the draft policy, "As the world's largest public funder of biomedical research, NIH is committed to ensuring that gold-standard science is conducted under gold-standard biosafety conditions. The purpose of the NIH Biosafety Policy for Research Involving Biohazards (the Policy) is to achieve this goal by setting forth requirements for federal and local institutional oversight of biomedical research involving biohazards, and to help ensure the safe, responsible, and secure conduct of such research."[2]

The draft NIH Biosafety Policy describes Institutional Biosafety Committee (IBC) review of certain clinical research, including challenge studies with RG2 or higher wild-type agents. NIH states that it aims to reinforce consistency with IRBs, but the draft does not describe how IBC and IRB review should be coordinated. PRIM&R requests guidance on review sequencing, information sharing between committees, and whether and how biosafety information should be addressed in the informed consent document.

[1] "Request for Information"; https://grants.nih.gov/grants/guide/notice-files/NOT-OD-26-112.html
[2] "Background"; https://grants.nih.gov/grants/guide/notice-files/NOT-OD-26-112.html

Further, the draft NIH Biosafety Policy requires IBC review and approval for research with primary cells that may be contaminated by "adventitious agents." It is unclear, however, whether NIH intends this category to include research with human tissue and specimens, which may also be subject to IRB review. We request NIH clarify the intended scope.

With respect to incident reporting, PRIM&R notes that certain incidents in clinical research may be reportable both under human subjects regulations and under the draft policy's requirement to notify NIH within 24 hours of incidents that pose a significant risk to human health. These obligations involve different committees, different timelines, and potentially different federal agencies. The draft policy does not appear to address how they should be coordinated. PRIM&R requests guidance on harmonizing these reporting processes.

Lastly, the draft NIH Biosafety Policy states, "any research subject to this Policy that is also under the regulation or purview of another federal agency may proceed under the oversight of the other federal agency once approvals or other applicable clearances have been obtained."[3] The draft also states that "clinical research cannot be initiated until IBC, and all other applicable institutional and regulatory authorization(s) and approvals have been obtained." [4] The draft policy does not explain, however, how these provisions apply to FDA-regulated trials, including whether IBC review is still required. PRIM&R requests that NIH clarify these requirements, as IRBs and institutions will need this information to fulfill their oversight responsibilities and avoid potential duplicative or conflicting review requirements.

As biosafety oversight continues to evolve, particularly in light of ongoing discussions around dual-use research of concern and the expanding scope of federally funded biomedical research, PRIM&R looks forward to serving as a resource and thought partner to NIH and other federal agencies on these issues.

Thank you for your consideration of these comments.

Sincerely,

Ivy R. Tillman, EdD, CIP
Executive Director
Public Responsibility in Medicine and Research (PRIM&R)

RE: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Director Young:

The University of Texas System ("UT System") submits the following comments in response to NIH Notice NOT-OD-26-112 requesting public input on the Draft NIH Biosafety Policy for Research Involving Biohazards. UT System comprises 13 institutions conducting research across a broad spectrum of disciplines. UT institutions collectively conduct more than $1 billion worth of NIH-funded research annually and have extensive experience securely managing biohazardous material at multiple safety levels.

UT System and its institutions are strongly committed to the highest standards of biosafety and biosecurity. We support NIH's goal of modernizing the biosafety oversight framework to reflect the evolving nature of biomedical research. We echo comments offered by the Association of American Medical Colleges (AAMC) and offer the following feedback to strengthen the clarity, consistency, and administrability of the proposed policy, around six key areas:

1. Scope and Definition of Biohazards (Section II)

The definition of "biohazard" requires clarification to ensure consistent application across the research enterprise. Specifically, UT System recommends that NIH:

- Clarify whether the scope includes bloodborne pathogens (BBPs), environmental samples, animal-only pathogens, and agents with uncertain pathogenicity, as these categories appear implicitly referenced in other sections but are not addressed by the stated definition.
- Resolve inconsistencies in the policy's "known or potential risk to human health" threshold with sections that reference zoonotic agents, GDMOs presenting environmental/ecological risks, and animal-related procedures, to clarify which activities require IBC oversight.
- Address the policy's broad application to all research at an NIH-funded institution—not just NIH-funded projects—and the significant compliance implications this creates for research funded by other sponsors.
- Provide a distinct definition and review pathway for research conducted in clinical settings, which do not conform to BSL containment levels but are otherwise included in the policy's scope.

2. Tiered Oversight and IBC Review (Sections IV-1 through IV-3)

UT System supports the tiered oversight framework and its risk-calibrated approach. To improve administrability, we request NIH address the following:

- Establish a clear mechanism and timeline for NIH review of emerging, novel, and zoonotic agents lacking an established Risk Group (RG) classification or containment level in the BMBL. Without defined timeframes, institutions and investigators cannot plan for the additional administrative burden.
- Clarify whether NIH-published determinations on higher-risk agents would eliminate the need for individual protocol submissions, or whether separate submissions would remain required.
- Define whether inactive toxin derivatives, isolated subunits, and nucleic acids encoding toxins are classified as "toxins," "genetic modifications," or both, and specify the review tier applicable to each.
- Allow institutions flexibility in defining the scope of "minor amendments" eligible for delegated review and to specify whether non-voting IBC members may conduct delegated reviews.

3. Risk Group Classifications

UT System agrees that Risk Group classifications remain an essential foundation for biosafety risk assessments and support their continued use. We encourage NIH to:

- Establish and maintain a dynamic, publicly accessible RG classification database that is updated in a timely manner as NIH completes reviews of novel and emerging agents.
- Provide expanded implementation guidance with concrete risk assessment examples and risk mitigation outlines to ensure consistent application across institutions.

4. IBC Meeting Minutes and Documentation (Section V)

The proposed documentation and public transparency requirements present significant practical concerns as currently written. We respectfully request NIH incorporate the following clarifications to avoid confusion and prevent the unintentional disclosure of information protected under state and federal law:

- Expertise Documentation: Requiring IBC minutes to document individual members' expertise is duplicative where an institution maintains a publicly available IBC roster. NIH should allow the roster to satisfy this requirement.
- Project Descriptions: NIH should clarify the expected level of project detail in publicly available IBC minutes while ensuring that proprietary, commercially sensitive, or pre-publication research information is appropriately protected.
- Privacy and PII: Publicly available minutes must not contain personally identifiable information. NIH should establish clear standards for what must be reported vs. what may be redacted.
- Required vs. Recommended: The draft should distinguish between requirements and recommendations when referencing items "to the maximum extent possible," as this ambiguity creates compliance uncertainty.

THE UNIVERSITY OF TEXAS SOUTHWESTERN MEDICAL CENTER · THE UNIVERSITY OF TEXAS MEDICAL BRANCH AT GALVESTON
THE UNIVERSITY OF TEXAS HEALTH SCIENCE CENTER AT HOUSTON · THE UNIVERSITY OF TEXAS MD ANDERSON CANCER CENTER

5. Incident Reporting

UT System supports robust incident reporting to advance biosafety learning system-wide, and recommends the following modifications:

- Confidential, Not Public Posting: Incidents should be reported to the National Biosafety Data and Safety Analysis Center rather than posted on a public-facing institutional website. Mandatory public posting may deter reporting of near-misses and increase HIPAA and privacy liability.
- Scope of Reportable Incidents: The definition of reportable incidents should focus on biosafety-relevant events (biohazard exposure, release or potential release, equipment failures resulting in exposure, and significant near-misses). Routine occupational safety incidents unrelated to biohazards should be excluded.
- Confidential vs. Public Information: The policy should specify which information is provided to NIH confidentially vs. which information is intended for public disclosure. Institutions should retain authority to redact identifying information from any public-facing summary.

6. Administrative Burden and Renewal Cycle

The proposed three-year renewal cycle would substantially increase administrative burden on investigators and IBCs. Institutions currently operating under a five-year cycle could experience a near-doubling of renewal workload, straining biosafety program staffing and resources. UT System recommends:

- Adopting a risk-based or tiered renewal schedule that permits longer renewal intervals for lower-risk research with demonstrated compliance histories, while reserving more frequent review for higher-risk protocols.
- Clarifying the requirement to "periodically review" approved research beyond the formal renewal cycle, including specifying the frequency, scope, and triggers that would require notification to the IBC.

UT System thanks NIH for the opportunity to provide input and commends the agency's commitment to strengthening biosafety oversight. We appreciate NIH's consideration of these comments and are eager to work collaboratively with NIH to develop a final policy that is rigorous, clear, and administrable for the research institutions that must implement it.

Sincerely,

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The draft policy states that IBC approval may not exceed three years, after which the investigator must submit a de novo registration for review. Mandatory de novo review every three years would substantially increase workload for investigators, BSOs, IBC staff, committee members, and institutional officials. Conversely, a five-year cycle aligns more closely with the evolution of many funded research programs. A risk-based de novo renewal is recommended, and NIH should permit IBC approvals for up to five years, with temporary extensions allowed while institutional review is in progress. Additionally, existing expiration dates should be grandfathered in rather than requiring early renewal to conform to the new policy.

Revise the scope and definition of “biological agent” to refer to wild-type biological agents “associated with disease in healthy adult humans,” and state expressly in the scope section that research involving wild-type RG1 biological agents is not subject to the policy.

The policy does not preserve the exemptions developed under Section III-F and Appendix C of the current NIH Guidelines. The current exemptions incorporates decades of experience and risk based determinations of research activities that do not present a significant risk to human health or the environment. Without an explicit exclusions section, routine activities involving well-characterized host-vector systems, established cell lines, transgenic rodents, and other commonly used research systems could require IBC approval even though the same activities are currently exempt from the NIH Guidelines, which would greatly increase the burden on PIs, BSOs, and IBC members. NIH should include an “Exclusions” section in the policy which retains the exemptions in the current NIH Guidelines. NIH should also consider extending the exclusions to established low-risk model organisms and laboratory strains, including Caenorhabditis elegans, Drosophila melanogaster, and Escherichia coli B21. Additionally, NIH should establish a formal, transparent mechanism for adding, modifying, or withdrawing exclusions based on accumulated experience, scientific evidence, and technological development.

The draft defines a toxin as a protein or peptide produced by a living organism that causes harm in

humans. Plant-derived toxins should be excluded for consistency, since plants are excluded from the genetic-modification components of the policy's scope. Additionally, NIH should retain the established threshold of a human LD50 of less than 100 nanograms per kilogram body weight to identify exceptionally potent toxins and genes encoding exceptionally potent toxins that warrant heightened federal oversight. Toxins above that threshold should be excluded from the policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Risk groups are poorly suited to laboratory use because they describe risk to healthy adults in the community and reflect community exposure rather than laboratory conditions. Risk group assignments have been removed from the NIH Guidelines and are not comprehensively provided in the BMBL. If risk groups will be retained, NIH should provide a definitive source or clear criteria for assigning risk groups. Without standardized risk group classifications, institutions may reach different conclusions for the same agent, reducing consistency across the research community.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reports contain concentrated information about a specific event and the people, laboratory, and research activities involved. Public posting may discourage reporting of minor incidents or suspected exposures, especially for smaller laboratories where the combination of PIs name, biological agent, and personnel position may allow identification of the affected individual. Public posting should be limited to a summary of incidents that are reportable to NIH. Do not require the public summary to identify the Principal Investigator, department, medical response, or other details that could permit identification.

The policy includes a requirement to report delegated approvals "in full" in IBC meeting minutes, however it is unclear what is meant by "reported in full." NIH should clarify what information must be included for a delegated approval to be "reported in full." Institutional registration number, general research category, type of submission or amendment, broad biological materials, containment level, approval date, and material conditions should be sufficient to meet this requirement. Additionally, purely administrative amendments to add personnel or change room location that do not affect the biosafety risk assessment should be excluded from reporting in public minutes.

6. Other feedback relevant to this resource: Clarify the review category for primary cells and what likelihood of contamination requires full committee review. Primary human cells and tissues are already regulated under the OSHA Bloodborne Pathogens Standard, therefore requiring full committee review for these materials adds an additional burden for IBC members. NIH should allow delegated review for primary human cells handled under universal precautions and applicable bloodborne-pathogen requirements and when primary cells may contain a RG2 agent, consistent with the delegated-review pathway for work conducted directly with wild-type RG2 biological agents. Full committee review should be reserved for primary cells known or reasonably suspected to contain a RG3 or RG4 agent.

Role: Investigator/Researcher

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Medical microbiology and immunology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The new policy language would reclassify any nucleic acid that “can be transcribed or translated”, including most transiently introduced transfected plasmids, exogenous mRNAs, and several vaccine technologies as a "genetic modification." This is a fundamental error. This re-classification could lead to confusion, misunderstanding, and loss of public trust in routine RNA research and in recombinant vaccine technologies, with potentially devastating public health outcomes.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

477. Frank Sangiorgi

I am responding: On behalf of myself

Name: Frank Sangiorgi

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Neurobiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Title suggests a policy designed to promote an overarching view of biosafety, yet the Scope states that the Policy is tied to human health (e.g., "biomedical research in laboratory settings, involving biohazards"). A definition of "biohazard" is not provided in the General Definitions Section, yet the "National Biosafety Data and Safety Analysis Center is included. Furthermore, the Scope excludes plants, animals, and the environment, yet mention of animals and the environment appear later in the document, especially with respect to the prion definition being extended to both humans and animals. The gap between biosafety involving humans and biosafety concerned with animals and plants can be addressed by either limiting the new Policy to human health concerns, or by establishing collaborative connections to other federal agencies that will address hazards to animals and the environment.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Within the proposed oversight tiers (Section IV), there is overlap between Section IV-2 and Section IV-3 with regard to wild-type Risk Group (RG) biological agents. In addition, Section IV-3 places all transgenic organisms at BSL1/ABSL1 under IBC review and approval. Again, there is no definition of a transgenic organism, and the sentence may be construed to cover transgenic animals derived from agricultural animals and non-human primates. The majority of transgenic rodents do not present any severe biosafety risk, and are indeed exempt from the current NIH Guidelines. In the case of the broad term "transgenic organisms" then a risk assessment would be beneficial. While the use of Risk Groups are useful, and promoted in Section V-A as being harmonized with the BMBL 6th edition, the evaluation of transgenic organisms requires more information. The risk assessment of transgenic organisms would include a more comprehensive approach, including information of the experimental procedures used, the nature of the transgene (transcription factor vs structural protein-coding gene), along with the equipment available and even the expertise and knowledge of the researchers conducting the work. This type of assessment is the exact system that was promoted in the Listening Session for the Biosafety Modernization Initiative, and may lead the exemption of many transgenic animal models from NIH review.

3. Continued utility of Risk Groups: The use of Risk Groups as a baseline for risk assessment is generally appropriate when evaluating the particular biological agent for use as is, and when being considered for

genetic manipulation. However, as noted above in the response to Section IV-3 of the Policy, such an assessment would benefit from the considering the methods used in the experimental manipulation, the equipment used and the appropriateness of the physical and biological containment, and the knowledge and expertise of the individuals performing the research. Again, the opening call by the NIH Modernization Initiative for a risk-based Policy would benefit greatly by simply expanding from Risk Groups to the consideration of additional factors (as described in Section II-A-3 of the current NIH Guidelines) involved in a laboratory's research.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The mechanism to encourage and accommodate voluntary compliance by non-NIH funded institutions should mirror the current NIH Guidelines Section IV-D, with the overall approach that the NIH is a knowledgeable partner and willing to support research in any research institution that would reach out for assistance and review.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The Draft Incident Report Template does not distinguish between lower risk incidents (e.g., an animal scratch) versus higher risk incidents (e.g., the laboratory release of an RG3 microorganism). The reporting of higher risk incidents may be more instructive for many institutions looking for examples of certain incidents and the practices that were used in resolving those situations. Along with this idea of a "teaching moment", the template could use more flexibility in reporting, as not every institution is identical, and the inclusion of the principal investigator's name does not add any additional actionable information to the Report.

The Draft Meeting Minutes Template should not allow for the public disclosure of the principal investigator's name, institutional project numbers, sensitive animal research information, proprietary material and research results, and other details the would compromise the safety and security of the institution, institutional staff, and research personnel. That such information would be available not only to NIH but to other individuals, including any potential malicious actors, is presumably not the outcome that the work toward transparency was meant to achieve.

6. Other feedback relevant to this resource: Due to the changes suggested by this Policy, and in the furtherance of co-ordination between this Policy and the new DGOF and IROC Policy (particularly in terms of the attestations and addition information that are required by both Policies), a careful revision of the NIH Policy to address the points of contact with DGOF/IROC (such as experimental risk evaluations) would be beneficial. Perhaps a phased application of the new NIH Policy would allow universities and other institutions to conduct appropriate risk assessments and attestations and have those documents approved without interrupting the research presently being conducted.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy needs to clearly define terms so institutions can implement it as required. Any definition lists are very vague and some are missing altogether, such as GDMO. This is also needed that variety institutions can implement it consistently!

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): NIH should require limited preapproval requirements for high risk research or genuinely novel constructs and allow local IBCs to use SME to assess basic research.

3. Continued utility of Risk Groups: Research institutions need to have the flexibility to regulate low risk research depending on their specific risk tolerance, which depends on many factors.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Incident reporting should include standard de-identified summaries and redacted information to comply with HIPAA requirements.

There's needs to be clear federal thresholds that preserve confidential reporting. Management of low risk incidents should remain with local oversight.

6. Other feedback relevant to this resource: There needs to be a minimum 24-month transition phase to update programs and implement as needed.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): biomedical sciences

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The definitions of biohazards that fall under oversight are not well delineated leading to an excessively broad scope for oversight, especially for genetic modification. I do not have an issue with the first definition, given as "The introduction into cells, organisms, or viruses of nucleic acid molecules that meet any of the following criteria: Possess biological properties that enable introduction of stable alterations (e.g., mutations, insertions, or deletions) into the genome (e.g., cis elements involved in integration, gene editing); or Have the potential for one or more cycles of replication in a cell; or Can be transcribed or translated." This definition is easy to interpret and apply because it matches our current understanding and expectations of what activities constitute genetic modification.

The excessive scope in oversight is due to the second definition which includes "the introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means". Most of these named "means" represent causal mechanisms by which natural genetic variation can arise in reproducing organisms. For example, reassortment is a typical phenomenon observed in sexual reproduction and it generates genetic variation among offspring even when they are progeny of the same parents. Natural selection is only possible when there is a range of heritable and varied traits present in a population. A trait is heritable because the genetic variation that underpins it is the product of stable alterations to the genome. This second definition of genetic modification thus captures nearly all the natural genetic variation upon which natural selection occurs.

If our focus is on systematic and directed efforts at genetic modification, it is not sufficient to merely list processes that produce stable alterations to the genome. Further qualifiers are needed in this second definition, unless we want to start doing risk assessments for every mouse colony and flasks of cells. The second definition unnecessarily stretches the meaning of genetic modification to the point where it is now cumbersome to use.

The introduction of fluorescent marker into a flask of cells via molecular biology techniques is a relatively

undisputed example of genetic modification and that is captured by the first definition of genetic modification. However, our fluorescent marker won't be present in every single cell in the flask after this activity and if the heterogenous population of cells continues to reproduce it might jeopardize the stability of our alteration. Subsequently, we sort the already genetically modified cells for our fluorescent marker and retain only the cells with the fluorescence for continued cultivation, ensuring stable alterations through passaging. This would qualify as a second act of genetic modification under the second definition. However, in practice we are only interested in considered the risk of the first activity, because the passaging activity seems too trivial to evaluate for risk and is comparable to selective breeding of mice.

Leaving the second definition of genetic modification as-is will lead to requiring additional oversight of low risk and inconsequential activities that are ordinary natural events for cell culture and animal breeding. Given the mostly justifiable expansion of scope in oversight developed elsewhere in the draft policy on topics, this second definition of genetic modification seems like an unwise area to spend our attention and resources.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Biosafety officer should be more clearly defined in the policy to illustrate the type of competencies needed.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The current level of details requested on the required incident reporting template, if required to be publicly posted, will compromise the ability of institutions to maintain cooperation and open communication with investigators. The public facing report should be more limited in the information required to be published because details in the template (even with redaction) could allow the identification of individual parties due to the truly unique nature of research activities and the limited number of people who conduct such work worldwide. The public posting could breach the privacy of affected individuals, identify targets for intellectual property theft, and expose protected health information.

Researchers and investigators who believe they are negatively affected by public posting of the incident reports may become discouraged to file initial reports or cooperate by sharing incident details. Therefore, I think the publicly posted incident report template should be a different form from the NIH-bound reporting template.

480. Cheryl Flynn, MD

I am responding: On behalf of myself

Name: Cheryl Flynn, MD

Name of Organization: Mount Holyoke College

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): I am the medical/clinical member of our Institutional Biosafety Committee that reviews all research projects done by faculty involving

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: seems a bit over-reaching to me;

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I appreciate the opportunity to have delegated review. My read on these proposed changes is that all delegated reviews must get full committee approval anyway.

so perhaps instead of the full committee approval, it could be a report out of delegated review team and include "approved" research still in the minutes of the meeting for public reporting but not a formal full committee approval (which, in my opinion, would require me to review the entire research application, which seems at odds with the option of creating delegated review...).

3. Continued utility of Risk Groups: I'm unclear why the change is necessary; changing language if indeed it simplifies things is OK but researchers are quite attuned to the BSL language/categories now.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I support the requirement of incident reporting; but I do not support the public display of each and every incident. Requiring the detailed level of reporting for minor injuries in the lab is not a helpful use of staff or faculty time; further, publication of each event will seem like labs are unsafe simply due to the nature of students working with animals.

I would suggest requiring the reporting of all incidents; detail required on those of significance; and reporting in aggregate but by category of severity of incident.
much like in medicine, people will stop reporting errors/incidents if there if fault to be found and then we miss the opportunity to improve.
+++

the meeting minutes template is OK but requires much more detail for unclear benefit than the current format our institution uses.
I think there can be a more balanced approach to safety via public sharing of details and the appropriate confidentiality of researchers

Uploaded File: Draft-NIH-Biosafety-Policy-Comments_101926v7.docx

Description: Comments on NIH Draft Biosafety Policy

October 19, 2026

To NIH OSP,

Thank you for the opportunity to provide comments on the Draft NIH Biosafety Policy for Research Involving Biohazards. These comments are submitted from the perspective of an Institutional Biosafety Committee (IBC), at an academic research institution with extensive experience administering complex biosafety, laboratory safety, and regulatory compliance programs.

General Comments

Theme	Recommendation
1. **Scope and definitions**	Narrow the definitions of genetic modification and primary cells. Remove cell passaging, chemical mutagenesis, and radiation from IBC scope. Recognize existing occupational-health mechanisms for primary cell work.
2. **IBC Membership**	NIH should provide additional implementation guidance regarding public member recruitment, protection of personal information, and management of security concerns.
3. **Incident Reporting and Transparency**	In the interest of transparency, the NIH could instead post aggregate/de-identified reporting information together with incident responses (both Institutional and NIH/Oversight Agencies) annually. Narrow the NIH-reportable threshold to risk-relevant events. The new Policy opens the entity and its personnel to additional safety risks. This

	step to increase transparency may further endanger those who are doing research.
4. **Registration Cycle**	Replace the three-year de novo registration with a five-year cycle or risk-based intervals, retaining substantive annual review.
5. **Exemptions**	Carry the NIH Guidelines exemptions forward, including Appendix C and the rodent breeding and purchase exemption; state the Risk Group 1 exemption plainly.
6. **Biosafety Professional**	Requiring a biosafety professional only at BSL-3, BSL-4, and for gene drive research undercuts risk-based framing and permits delegation to unqualified personnel.
7. **Implementation Guidance**	Provide implementation guidance to increase consistency.

Specific Comments

1. Scope of the Policy

Recommendation

NIH should further clarify which activities are intended to be within scope and provide examples. Also, the NIH Guidelines contain where risk got defined. Institutions looked to them for Risk Group classification. If that reference disappears, it is unclear what institutions are meant to use in their place.

a. NIH should provide a detailed scope matrix that includes common examples of research activities that are in scope, out of scope, and conditionally in scope. This matrix should include work involving human specimens, RG1 organisms, environmental samples, microbiome studies, inactivated materials, plant pathogens, toxins (including nonpeptidic biological toxins), gene therapy products, viral vector-based genome screening libraries, and synthetic biology research. Such clarification would promote consistent

implementation across institutions and reduce variability in local interpretation.

i. “Toxins" need to be better defined. For example, limiting oversight to toxins that are proteins/peptides excludes toxins like tetrodotoxin or T-2 on the SA list. A specific list of toxins for which oversight is needed should be provided. This matrix should provide guidance for appropriate biosafety measures.

b. The Scope of the Draft Policy expands beyond recombinant nucleic acid research to cover emerging biotechnology research, but institutions require examples of such NIH biosafety policy coverage.

Rationale

Ambiguity may result in inconsistent implementation among institutions.

2. IBC Membership and Public Transparency

Recommendation

NIH should provide additional implementation guidance regarding public member recruitment, protection of personal information, and management of security concerns.

Rationale

Many institutions have faced sustained harassment, threats, legal action, and risks to the personal safety of individuals involved in research and or research oversight. These requirements are likely to intensify these challenges.

3. Incident Reporting

Recommendation

NIH should maintain similar reporting requirements and not require publicly posting incident reports. As stated above, providing information regarding the institution, its research, the animals used in that research, etc., opens the entity and its personnel to additional risks to safety. This requirement will not increase transparency; it will further endanger those doing research and making a difference. NIH should continue to monitor and review all incidents covered under the policy and not require that they be publicly

posted. In the interest of transparency, the NIH could instead post aggregate/de-identified reporting information together with incident responses (both Institutional and NIH) annually.

Rationale

Providing incident reports to the public will not help to provide transparency it will only increase the risk for threats and harassment to the institution while jeopardizing personal safety. This requirement may have the opposite intended effect and Principal Investigators may not report incidents for fear of public scrutiny or harassment.

4. Registration Cycle

Recommendation

Replace the proposed three-year de novo registration requirement with a five-year renewal cycle, while retaining annual investigator attestations and reviewing substantive protocol changes.

Rationale

For low-risk research that remains subject to registration, a five-year renewal cycle would reduce unnecessary administrative workload while preserving institutional awareness of ongoing activities. Annual attestations, amendment review for significant changes, incident reporting, laboratory inspections, and training requirements would continue to provide effective oversight and opportunities to identify changes that may alter the biosafety risk assessment. A longer renewal interval would allow IBCs and biosafety programs to devote more time and resources to higher-risk projects where detailed reviews provide the greatest benefit to personnel, public health, and the environment.

5. Exemptions

Recommendation

Create an exemption category or alternatively expand the scope of activities eligible for administrative registration without IBC review. Examples could include work with well-characterized cell lines, non-integrating and replication-incompetent vectors expressing low-risk transgenes, standard molecular biology experiments involving nonpathogenic agents, and other research with well-established biosafety profiles.

Rationale

The proposed policy significantly expands the scope of research subject to institutional oversight while eliminating the exemption framework that has historically allowed IBCs to focus resources on higher-risk research. As written, a substantial volume of low-risk, routinely conducted research would require either full IBC review or delegated review, increasing administrative burden for investigators, biosafety offices, and IBCs without a corresponding improvement in safety.

An exemption category would allow institutions to concentrate oversight on activities that present meaningful biosafety concerns, including work with Risk Group 2-4 agents, genetically modified organisms with uncertain risk profiles, emerging agents, and other higher-risk research. Such a risk-based approach is consistent with the stated goal of reducing administrative burden for low-risk research while strengthening oversight where it is most needed.

6. Biosafety Professional

Recommendation

The draft Policy states, “A BSO must be appointed when the institution conducts research subject to the Policy i) at BSL-3 or 4, or ii) involving GDMOs.” NIH should require that all institutions maintaining an Institutional Biosafety Committee (IBC) appoint a qualified Biosafety Officer or Biosafety Professional as a voting member of the IBC, regardless of the institution's current research portfolio.

Rationale

The IBC and BSO function most effectively as complementary components of the institutional biosafety program. While the IBC provides multidisciplinary review, oversight, and risk-based decision making, the BSO provides the day-to-day technical expertise, operational awareness, and implementation support necessary to ensure that biosafety practices are effectively applied throughout the institution.

Many institutions conduct research that is classified as lower risk under the proposed policy yet still involves complex biological agents, recombinant or synthetic nucleic acids, human materials, viral vectors, toxins, or emerging technologies that benefit from professional biosafety risk assessment and oversight. Requiring a BSO only when BSL-3/4 research or GDMOs are present creates an artificial threshold that may leave institutions without dedicated biosafety expertise despite maintaining active IBC programs.

A qualified biosafety professional provides continuity between IBC meetings by assisting investigators with risk assessments, evaluating containment strategies, conducting laboratory inspections, supporting incident investigations, monitoring compliance with IBC approvals, providing training, and serving as a resource to researchers and institutional leadership. These activities strengthen biosafety culture and improve the quality and consistency of IBC reviews.

In addition, the draft policy substantially expands the scope of oversight beyond recombinant and synthetic nucleic acid research to encompass a broad range of biohazards. As institutional responsibilities increase, the need for professional biosafety expertise likewise increases. Requiring a BSO for all institutions with an IBC would promote consistent implementation of the policy, improve institutional compliance, and enhance the safe conduct of research across the biomedical enterprise.

7. Implementation Guidance

Recommendation

NIH should develop:

- Frequently Asked Questions
- Decision trees
- Risk categorization examples
- Model SOPs
- Training modules
- Example IBC review documentation

Rationale

These resources would promote consistent implementation across the research enterprise.

Conclusion

NIH's efforts to modernize biosafety oversight and support the development of a unified, risk-based framework that promotes the safe and responsible conduct of research involving biohazards, are appreciated. The draft Policy represents an important opportunity to strengthen biosafety oversight while providing clarity and consistency across the research enterprise.

As drafted, however, several provisions may unintentionally expand oversight of lower-risk activities, increase administrative burden, and create implementation challenges without providing a commensurate improvement in biosafety outcomes. In particular, clearer definitions, preservation of appropriate exemptions, meaningful implementation guidance, and greater flexibility in registration and reporting requirements would help ensure that institutional resources remain focused on activities that present the most significant biosafety risks.

We also encourage NIH to carefully consider the potential unintended consequences of public incident reporting and other transparency provisions that may increase risks to researchers, biosafety professionals, IBC members, and institutions. Transparency is an important objective, but it should be achieved in a manner that promotes accountability without compromising personal safety, security, or the open reporting culture that is essential to effective biosafety programs.

Finally, successful implementation of the Policy will depend on the availability of clear guidance, practical tools, and sufficient institutional expertise. Providing FAQs, decision trees, examples, and other implementation resources will help foster consistent interpretation and application of the Policy across institutions of varying size and complexity.

We respectfully encourage NIH to incorporate these recommendations as it refines the final Policy. Doing so will help ensure that the framework remains science-based, risk-informed, practical to implement, and effective at advancing biosafety while supporting the continued success of the biomedical research enterprise. Thank you for the opportunity to provide these comments and for NIH's continued leadership in promoting biosafety and responsible research practices.

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: In general, I like the unification of oversight for all research involving biohazards, whether or not such research involves recombinant or synthetic nucleic acid technology. It is a positive change which supports a more comprehensive and cohesive institutional biosafety program. However, there are areas where I believe the draft goes to far and will result in overly burdensome requirements for very low risk activities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The addition of a Delegated Review mechanism is another positive change. It should reduce the burden on IBCs, while providing institutions with the flexibility to define the Delegated Review process in a way that ensures appropriate oversight of lower-risk activities at individual institutions.

3. Continued utility of Risk Groups: I agree using Risk Groups as a baseline for risk assessment is appropriate. However, biosafety levels are also an important consideration.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: New incident reporting requirements have an expanded scope of what counts as an incident in addition to the requirement to post all incident reports on a public website.
a. Impact: These changes are expected to have a significant negative impact. The trust that biosafety programs have built up over the years in supporting researchers and encouraging people to report accidents will be eroded by fear of negative ramifications and/or retaliatory action. Even if reporting is anonymized and only a PI or supervisor name is included in the published report, there is a perceived risk of that information being used against the person, lab, and/or institution. People will be less likely to report accidents, which increases the risks associated with untreated injuries or exposures to hazardous materials.
b. Recommendation 1: Individual incident reports should not be publicly posted. Reporting should be to NIH, where data on incidents can be aggregated and trends analyzed and/or reported in a way that removes institutional affiliation to further anonymize individuals involved in an incident. That allows for

analysis of the data and identification of trends, which would be a valuable resource to the community, while avoiding negative consequences on the individual, lab, or institution, which would, in turn, undermine the value of the incident reporting process.
c. Recommendation 2: If institutions must be required to publicly post incident information, allow an aggregated annual report. Such an approach could be modeled after OSHA's Form 300A (Summary of Work-Related Injuries and Illnesses). We would strongly recommend this approach for incidents defined by this Policy, which would not be reported to NIH but would be reported to the IBC.

6. Other feedback relevant to this resource: I greatly appreciate the outreach and request for feedback that NIH has made with regard to updating this policy.

Uploaded File: Comments-on-proposed-NIH-Biosafety-Policy-Updates.docx

Description: Attached are comments that were circulated, reviewed, and generally approved by a broad group of Biosafety Professionals.

Comments on the proposed updates to the NIH Biosafety Policy:

In general, we like the unification of oversight for all research involving biohazards, whether or not such research involves recombinant or synthetic nucleic acid technology. It is a positive change which supports a more comprehensive and cohesive institutional biosafety program. The addition of a Delegated Review mechanism is another positive change. It should reduce the burden on IBCs, while providing institutions with the flexibility to define the Delegated Review process in a way that ensures appropriate oversight of lower-risk activities at individual institutions. We support these notable policy improvements.

While many aspects of the draft Policy represent improvements, there are several changes that are likely to have significant negative consequences, as well as points that would benefit from clarification. We respectfully submit the comments below for consideration to further improve the Policy.

New incident reporting requirements have an expanded scope of what counts as an incident in addition to the requirement to post all incident reports on a public website.

a. **Impact:** These changes are expected to have a significant negative impact. The trust that biosafety programs have built up over the years in supporting researchers and encouraging people to report accidents will be eroded by fear of negative ramifications and/or retaliatory action. Even if reporting is anonymized and only a PI or supervisor name is included in the published report, there is a perceived risk of that information being used against the person, lab, and/or institution. People will be less likely to report accidents, which increases the risks associated with untreated injuries or exposures to hazardous materials.

b. **Recommendation 1**: Individual incident reports should not be publicly posted. Reporting should be to NIH, where data on incidents can be aggregated and trends analyzed and/or reported in a way that removes institutional affiliation to further anonymize individuals involved in an incident. That allows for analysis of the data and identification of trends, which would be a valuable resource to the community, while avoiding negative consequences on the individual, lab, or institution, which would, in turn, undermine the value of the incident reporting process.

c. **Recommendation 2**: If institutions must be required to publicly post incident information, allow an aggregated annual report. Such an approach could be modeled after OSHA's Form 300A (Summary of Work-Related Injuries and Illnesses). We would strongly recommend this approach for incidents defined by this Policy, which would not be reported to NIH but would be reported to the IBC.

2. The draft Policy states that IBC approval should be granted for a period not to exceed three years, at which time a de novo registration submission and review is required. It further lists failure to maintain IBC approval as a reportable incident.

    a. **Impact:** The expected impacts of these changes are a significantly increased administrative burden and unintentional non-compliance. In the absence of a specified term limit, many institutions adopted internal policies that require IBC approval to be renewed within a 5-year period, which also coincides with the length of many grants supporting the approved research activities. Switching to a shorter 3-year renewal cycle presents a significant increase in committee workload. Additionally, well-intentioned PIs may face unexpected emergencies, or their registration renewal may come at a time when they are burdened with high workloads from teaching and/or other institutional responsibilities. Because there is no mechanism described in the draft Policy for allowing extensions to PIs facing extenuating circumstances, failure to renew an IBC registration on time would result in a reportable incident of non-compliance.

    b. **Recommendation 1:** Keep a defined term limit on IBC approval but increase the term of IBC approval to 5 years.

    c. **Recommendation 2:** Empower IBCs to exercise judgement and flexibility in granting reasonable, one-time extensions to PIs facing extenuating circumstances and/or moving a registration renewal to a different time of year so as not to conflict with other high-workload periods.

3. The draft Policy states that research with primary cells that may be contaminated by adventitious agents requires IBC review and approval under Section IV-2. We interpret this new scope to mean that any primary human cell line, tissue, or clinical specimen with an unknown status (has not been tested for bloodborne pathogens or other infectious agents) will have to go to the IBC for approval, whereas none of this material required IBC review previously. Instead, this material fell under the OSHA Bloodborne Pathogens Standard, which requires institutions to establish oversight mechanisms that have worked for many decades.

    a. **Impact**: This change is expected to have a significant negative impact. The increased burden on most IBCs will be enormous, with no apparent benefit, since the existing mechanisms to comply with the OSHA Bloodborne Pathogens Standard must still be maintained. This is an unnecessary duplication of oversight, and the increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation**: Allow this type of material to be approved via the new Delegated Review process described in Section IV-3 rather than requiring IBC

review. That would allow institutions flexibility to integrate existing biosafety oversight mechanisms into the Delegated Review process defined by the new Policy.

4. The draft Policy states that research involving genetically modified cells, viruses, or organisms, other than plants requires IBC approval and approval under Section IV-2. Previously, a large portion of genetically modified cell lines were considered exempt under Section III-F-8, Appendix C-I. For many IBCs, that type of material made up the majority of genetically modified material, and because it was considered exempt and did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely and in accordance with the OSHA Bloodborne Pathogens Standard. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8, Appendix C-I now falls under Section IV-2 and requires full committee review.

    a. **Impact**: This change is expected to have a <u>significant negative impact</u>. This will create an enormous new burden on IBCs, with no apparent benefit because the main risk associated with material that fell under Section III-F-8, Appendix C-I was the risk of adventitious agents or bloodborne pathogens, as mentioned in point 3 above. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation**: Retain the Section III-F-8, Appendix C-I exemption, or allow materials that would have fallen under Section III-F-8, Appendix C-I to be approved via the Delegated Review process described in Section IV-3.

5. The draft Policy's definition of a genetic modification includes introduction into cells, organisms, or viruses of stable alterations into the genome by passaging. It is not clear what passaging activity falls within the Policy scope. Simply culturing an organism in vitro will lead to accumulation of undefined genetic alterations and could be considered passaging. Cultures that are maintained in a lab are also considered to be passaged through the process of sub-culturing to create multiple stocks from an original sample. Further, most of the time, growing an organism in vitro or in a model system selects for mutations that optimize growth in a lab environment, not in a human host, and these lab-adapted strains typically lose virulence or pathogenicity. The Influenza A/Puerto Rico/8/1934 (H1N1) strain (often called PR8 influenza) is a classic, mouse-adapted laboratory strain of the influenza A virus isolated from a human patient in Puerto Rico in 1934. It is an example of a strain that is a lower risk option for studying influenza. These examples of passaging generally have not required IBC review. In the draft Policy, all of these activities would require IBC review and approval under Section IV-2 (see also point 4 above).

a. **Impact**: The current definition of genetic modification is expected to have a significant negative impact. This will create an enormous new burden on IBCs, with no apparent benefit because most passaging does not increase the risk of the agent or associated research activities. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

b. **Recommendation**: We recommend refining the scope of the definition of genetic modifications by defining passaging as the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile. Examples of passaging activities that should be included in Section IV-2 include passaging with the intent or likelihood for an agent to acquire a new virulence trait or antibiotic resistance or to adapt a pathogen to a new host species and/or tissue tropism.

6. In the draft Policy, the definition of genetic modification that falls within the scope of the policy now includes modification via chemical or radiological means. Further, the draft Policy requires the IBC to review all genetically modified cells under Section IV-2 (see also point 4 above). The main risk associated with use of chemical or radiological agents to create mutations is in the handling of the chemical or radiological material, not necessarily in handling the cells once the mutagen has been removed. There are separate regulations that apply to chemical and radiological hazards. The use of chemical and radiological hazards is best handled by the respective safety experts who are familiar with the appropriate regulations and safety requirements, not the IBC. Assessment of the risks of these mutagens are outside of the scope of an IBC, since IBC members typically have little to no expertise on chemical or radiological hazards.

    a. **Impact**: This is a vast expansion of scope that will duplicate oversight and increase burden on IBCs, without a clear benefit. Further, the IBCs typically lack appropriate expertise for evaluating the risks associated with these mutagens. The increased burden on IBCs will detract attention from higher-risk matters, which do fall within the expertise of the committee.

    b. **Recommendation**: Remove chemical and radiological means from the definition of genetic modifications that fall within the scope of the policy and defer oversight to existing regulations that apply to the use of chemical and radiological hazards. Alternatively, refine the scope to apply to experiments in which the mutagenic agent is combined with the deliberate culturing of an organism under a selective pressure that could reasonably be expected to lead to an organism with a higher-risk profile, as recommended for passaging in point 5 above.

7. The draft policy states that research with genetically modified RG1 biological agents requires Delegated Review under Section IV-3. Previously, most standard cloning and/or

protein expression with *E. coli* and other model host-vector systems were considered exempt under Section III-F-8, and it did not require any level of review. Many institutions have adopted internal review and approval mechanisms as a safeguard to make sure those materials really were exempt and were still being handled safely with proper waste disposal procedures. In the draft Policy, there is no carve-out for exempted materials, so everything that previously fell under Section III-F-8 now requires Delegated Review.

a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. The increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

b. **Recommendation 1**: We strongly recommend retaining existing III-F-1 through III-F-8 exemptions.

c. **Recommendation 2**: Furthermore, and supported by decades of safe research experience, we also recommend expanding the exemptions to include other low-risk cloning and protein expression research in model organisms such as *E. coli* BL21 strains, *C. elegans*, and *Drosophila*.

8. The draft Policy states that research conducted with transgenic organisms at BSL-1/ABSL-1" requires Delegated Review. Previously, almost all breeding or purchasing of transgenic rodents was exempt under Section III-F-8, Appendix C-VII and was not typically registered with an IBC at all. Instead, oversight of those transgenic rodents typically has been handled through federally mandated Institutional Animal Care and Use Committees (IACUCs) that have biosafety professionals as members who conduct risk assessments and suggest risk mitigation measures as part of that review process. Many IBCs do not even have a mechanism for tracking this information. Additionally, many researchers using transgenic mice are not using any other sort of biological material; the research is often focused on behavioral studies or pre-clinical studies that fall outside the scope of an IBC. A very large proportion of transgenic animal work is done with transgenic rodents and zebrafish, and almost all of that work poses no new risk compared to the unmodified rodents and zebrafish.

    a. **Impact**: This will be an enormous new burden on IBCs and/or Biosafety programs that do not already have internal biosafety oversight mechanisms for reviewing this work, with no apparent benefit. Again, the increased burden on IBCs and Biosafety staff will detract attention from higher-risk matters.

    b. **Recommendation 1**: We strongly recommend retaining the III-F-8, Appendix C-VII exemption and allow existing oversight of these low-risk animals to continue via the IACUC.

c. **Recommendation 2**: As mentioned in point 7 above, we also recommend expanding the exemptions to include other low-risk transgenic model organisms such as zebrafish, *C. elegans* and *Drosophila*.

9. The draft Policy defines biological agents that fall within the scope as bacteria, viruses, fungi, or parasites that cause human disease. This definition seems to contradict the draft Policy's requirement for Delegated Review of research with genetically modified RG1 biological agents (see point 7 above). Risk Group 1 agents are <u>not</u> associated with disease in healthy adult humans. Some agents may be considered opportunistic pathogens, but there is currently no list of RG1 organisms that are considered opportunistic pathogens.

    a. **Recommendation 1:** NIH should clarify the nature of biological agents that fall within the scope of the Policy. We recommend that the Policy scope is limited to pathogenic biological agents that cause disease in humans, including opportunistic pathogens but <u>excluding</u> non-pathogenic agents.

    b. **Recommendation 2**: As there is no list of RG1 agents, and the list of RG2 agents is incomplete, we further recommend empowering the IBCs, Biosafety programs, and PIs to make the determination of RG1 and RG2 for biological agents that are not currently listed in Appendix B of the NIH Guidelines or the BMBL using the risk assessment guidance provided therein.

10. The draft Policy's definition of a genetic modification includes introduction of materials that can be transcribed or translated. This would include materials such as purified or synthetic miRNAs, snRNAs, shRNAs, and mRNAs, which are transient in nature and may lead to changes in gene expression but do not replicate and do not modify or integrate into the genome. Work with such materials was previously exempted under III-F-1 but would now fall under Section IV-2 and require IBC review and approval.

    a. **Impact**: The current definition of genetic modification is expected to have a <u>significant negative impact</u>. This will create a significant new burden on IBCs, with no apparent benefit given that no genetic modifications are made with these materials. The increased burden on IBCs will detract attention from higher-risk matters that deserve IBC attention.

    b. **Recommendation:** We recommend retaining the III-F-1 exemption and removing these materials from the scope of the Policy.

11. The scope of the draft Policy includes prions and self-aggregating proteins, and research activities involving these materials would require IBC review and approval. We support the draft Policy as it pertains to prions, but request refinement of the oversight pertaining to self-aggregating proteins. IBC oversight should not extend automatically to every protein capable of self-aggregation. Protein aggregation is common in biology and,

by itself, does not establish an infectious or exposure hazard. Oversight should instead focus on proteins or protein assemblies for which there is credible evidence that an aggregated conformer can act as a persistent, self-propagating seed; induce conformational conversion of the corresponding native protein; spread between cells or tissues; and transmit pathology following experimental exposure or inoculation. We recommend the following risk-assessment approach, which is consistent with the BMBL principle that containment decisions should be protocol-driven rather than based only on an agent's name.

a. **Recommendation 1:** Classical mammalian prions and prion-containing tissues should remain categorically within IBC purview because of their established infectivity, potential for serious disease, environmental persistence, and resistance to conventional inactivation procedures.

b. **Recommendation 2:** Seed-competent aggregates of α-synuclein, including preformed fibrils, amplified seeds, and α-synuclein-containing material derived from affected human or animal tissue, should also be subject to IBC review because α-synuclein assemblies have demonstrated prion-like templating, cellular and anatomical propagation, and experimental transmissibility in animal models. Inclusion under IBC oversight should not be understood to mean that α-synuclein is known to be naturally communicable between people or that it presents the same level of hazard as a classical prion.

c. **Recommendation 3:** Other self-aggregating proteins should be evaluated individually rather than be included in Section IV-2 of the draft Policy solely because they form oligomers, fibrils, or amyloid. Relevant considerations should include evidence of experimentally transmissible pathology, persistence of seeding activity, resistance to standard decontamination, source and concentration of the material, route and scale of exposure, use of human- or animal-derived pathological tissue, and procedures involving inoculation, sharps, aerosols, or other opportunities for occupational exposure. Routine work with non-seed-competent monomeric proteins or aggregates lacking evidence of biological propagation would not ordinarily require specialized biosafety review beyond the requirements otherwise applicable to the experimental system, and we recommend that the Delegated Review mechanism described in Section IV-3 be applied to such work.

12. The scope of the draft Policy includes toxins listed as Select Agents, and research activities involving these materials would require IBC review and approval under Section IV-2, while research with biological toxin proteins not on the Select Agent list may be approved by Delegated Review under Section IV-3. We support this overall approach; however, we request refinement of the Policy with the following recommendations.

a. **Recommendation 1:** Allow research activities using exempt amounts of Select Agent toxins to be approved by Delegated Review. Most institutions have already developed effective internal biosafety oversight mechanisms for handling these exempted materials. Integrating those internal oversight mechanisms into the Delegated Review process would allow IBCs to focus on the higher-risk Select Agent work.

b. **Recommendation 2:** Either publish a list of biological toxins that fall within the scope of the Policy or use a threshold toxicity value as a risk-based factor for determining whether a biological toxin requires oversight by the Policy. We further recommend that biological toxins that have an LD_{50} greater than 1000 µg/kg be exempt from this Policy.

13. The scope of the draft Policy includes cells, viruses, or organisms, other than plants, that have been genetically modified. It is assumed that animals are included as organisms, but it is not clear what is considered an animal under this Policy.

    a. **Recommendation:** Use a definition of animal that is consistent with the Guide for the Care and Use of Laboratory Animals, which has been adopted by the NIH Office of Laboratory Animal Welfare, and which defines animals as any vertebrate animal (i.e., traditional laboratory animals, agricultural animals, wildlife, and aquatic species) produced for or used in research, testing, or teaching.

14. The draft Policy indicates that the effective date will be 6 months from publication of final Policy, and that applicability includes ongoing work. It is unclear how ongoing work will be impacted by the new review and approval requirements. Work that was not subject to IBC oversight according to the NIH Guidelines may have been approved via voluntary institutional biosafety oversight mechanisms.

    a. **Impact:** Work that was approved by a Biosafety Officer (or other institutional biosafety oversight) and now requires a higher level of review by the IBC would need to cease until IBC approval is obtained. This would have a significant negative impact on a large number of projects that are suddenly subject to new oversight, thereby wasting grant money and setting back important research projects.

    b. **Recommendation:** Require activities that have not received approval by a Biosafety Officer or other institutional biosafety oversight mechanism to be reviewed and approved according to the final Policy within 6 months of the publication of the final Policy. For activities that have received approval by a Biosafety Officer or other institutional biosafety oversight mechanism, allow the existing approval to remain in place until such time as de novo registration is

required (see point 2 regarding our recommendation to allow 5-year term limits for IBC registration approvals).

483. Rebecca Cederberg

I am responding: On behalf of myself

Name: Rebecca Cederberg

Name of Organization:

Type of Organization: Academic Institution

Role: Other

Role - Other: biosafety

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I support the NIH's effort to strengthen biosafety oversight and have a risk-based approach to mitigating safety hazards associated with biological research. However, the described scope and definitions lack details and examples and are confusing in regards to animal and plant pathogens; this is a missed opportunity to take a One Health approach for addressing research safety with biological materials. Plant pathogens appear to not be covered in the new policy, but biomedical researchers have evaluated plant and animal viruses as vaccine candidates, would this use of a plant pathogen be covered under this policy, but not the use of a plant virus to generate a genetically modified plant? Implementation guidance is needed to clarify what materials/work are covered by the policy. Previously, there was some low-risk work with r/sNA that was exempted from the NIH Guidelines or could be initiated with notification to the IBC, now it would appear those exempt activities require review and approval before initiation. Are activities with r/sNA outside of a cell exempt under the new policy?
The 6-month implementation timeline is not reasonable given the large shift in scope from the NIH Guidelines. Most institutions will require additional personnel and resources to register the expanded number of research faculty.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Section III-D states that NIH will provide interpretation for cases in which the Policy does not specifically assign containment levels. There are many non-pathogenic environmental and commensal microorganisms that are not listed in the BMBL. It is not obvious when NIH must be contacted to set containment level of research with microorganisms not specifically listed in the BMBL (does the work fall within scope of this policy?) or what would be classified as novel work requiring NIH consultation. In the NIH Guidelines, the description of research activities has assisted local IBC's in assigning a level of risk to work with r/sNA that could be categorized into a guideline. If the description of research activities is no longer a starting point for a risk assessment of work, will NIH be providing resources to supplement the loss of the Section III and the appendices of the NIH Guidelines? Will NIH post determinations that have been made on behalf of other entities as a resource for other IBCs?

3. Continued utility of Risk Groups: There is often confusion about RG and how that impacts a containment level assignment for described work. While it is a good starting point in the risk assessment of a human pathogen, the lack of a corresponding assignment for plant and animal pathogens can be confusing for researchers. A unified, dynamic reference tool for microorganisms is needed.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Ideally, a policy for research involving biohazards would not live in a single federal agency or subject to funding status. A comprehensive policy done in conjunction with other federal agencies would provide better oversight and the ability to make compliance a requirement of working with regulated materials regardless of funding source.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: While I strongly support a national database of incidents and injuries, as this would be an invaluable learning tool for the research and safety community and I am incredibly concerned about the requirement to include names and all details about the agent and work. Some PI labs are small enough, that sharing the researcher name may allow external groups to identify the specific individuals that were injured. Additionally, sharing agent/work information may be counter to Federal Select Agent biosecurity requirements. It is a security concern to call out agent information, particularly when it may not provide useful information to prevent future incidents.

6. Other feedback relevant to this resource: The National Academies “Supporting Responsible Innovation of Synthetic Cells: Biosafety , Biosecurity, and Environmental Considerations” is a good resource for safety assessments of synthetic cell novel research https://www.nationalacademies.org/projects/DELS-BLS-22-12/publication/29325 .
Examples of covered materials and activities are needed to clarify how this policy removes red tape for low-risk research if previously exempt work (i.e., purchase and transfer of transgenic rodents) now requires registration and review.

484. N/A

I am responding: On behalf of an organization

Name:

Name of Organization:

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): High Containment Infectious Disease Research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: While the conceptual goal is unified and biosafety architecture is commendable, the current draft contains several structural ambiguities, excessive expansion of institutional liability, unrealistic reporting timelines, and a lack of necessary implementation resources. If finalized without substantial structural revisions, the policy threatens to overwhelm Institutional Biosafety Committees (IBCs), creates compliance bottlenecks, and disproportionately penalize smaller institutions.
1. Ambiguity and Overbreadth in Scope and Definitions
Critique: The draft policy restricts its scope to “biohazards,” but strangely, it does not provide a clear, stand-alone definition of the term itself, but rather a descriptive checklist of materials and human-health risk criteria. Further, the inclusion of “toxins, prions, and other self-aggregating proteins” without rigid concentration, mass, or activity thresholds creates enormous regulatory gray zones. Routine biochemistry and structural biology labs working on common, non-pathogenic proteins or minuscule quantities of common biochemicals are in danger of being unknowingly caught up in heavy IBC oversight.
Recommendation: Add a precise, legally-clear definition of “biohazard” directly into Section II. Develop clear, quantitative criteria (e.g., specific mass limits for toxins or biological activity units) to exempt low risk protein and biochemical research from required review at high levels of containment.
2. Increased Administrative Burden
Critique: The policy states that if an institution receives any NIH funding for any purpose, then all biomedical research conducted at that institution must comply with the policy, whether or not the research is funded by NIH, private industry, state grants or institutional funds. Taking this requirement from recombinant molecules to all biohazards is a dramatic increase in compliance footprint. This will be an administrative and financial burden that will be impossible for smaller academic institutions, teaching hospitals, and research institutes with minimal NIH funding to handle.
Recommendation: a)Restrict the institution-wide compliance mandate to only high-consequence or high-risk research categories (e.g., BSL-3/4 agents or dual-use research of concern). b)Allow use of streamlined self-certifying or periodic audit structures in place of full protocol-by-protocol IBC reviews for low-risk (BSL-1/BSL-2) non-NIH-funded projects.

3. Other Risks not Included in this Draft Policy
Critique: The draft policy does not address plants, plant pathogens, animals, or animal pathogens. This creates a gap that requires additional oversight by other government agencies; a key area of concern brought forth in all listening sessions.
Recommendation: NIH should consider a One Health approach that involves collaboration across funding agencies to reduce administrative burden while providing adequate oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): No comments

3. Continued utility of Risk Groups: 1. Critique: Risk Group assignments have been removed from the NIH Guidelines and are not comprehensively provided in the BMBL.
Recommendation: NIH should provide a definitive source or clear criteria for assigning Risk Groups to non-recombinant agents. Without standardized Risk Group classifications, institutions may reach different conclusions for the same agent, reducing consistency across the research community.
2. Please provide the biosafety rationale and supporting evidence that prompted the inclusion of additional oversight requirements for research involving insect cell lines, non-human/NHP cell lines, and pathogens that are not capable of causing disease in humans, including immunocompromised individuals. Clarification of the specific risks, incident history, or emerging concerns that necessitate these requirements would help the research community understand the basis for the policy change and assess whether the proposed oversight is proportionate to the actual biosafety risk posed by these systems.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): No Comments.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: 1. The proposed definition of an incident appears overly inclusive and may capture events with minimal biosafety significance. A broad incident definition could result in unnecessary reporting requirements, diverting resources from investigating and addressing more consequential biosafety events.
Critique: The draft calls for aggressive reporting windows, such as requiring a 24-hour notice for incidents with potential human health risks. Draft templates threaten to lump serious breaches of containment in with minor “near-misses” inside the lab. Publicly posting the details on every minor, internally resolved anomaly will swamp IBCs with paperwork, encourage under-reporting due to fear of public exposure, and fill federal regulators with noise rather than actionable safety intelligence.
Recommendation: a)Identify critical safety breaches (to be reported to federal government within 24 hours) vs. minor anomalies/near-misses (to be internally root-cause analyzed and included in annual institutional reports). b) Promote voluntary, internal near-miss reporting with safe-harbor provisions to encourage a culture of safety, not a culture of compliance avoidance.
2. The level of detail requested per registration in the Draft Meeting Minutes Template is so onerous that it seems it would be easier to just attach copies of each entire registration. For instance, if no training concerns were discussed for a particular registration, why must every training for every listed personnel be included in the minutes? Shouldn’t the Project Overview just be the Lay Summary? If a single registration utilizes 10 agents, are we expected to list every agent and describe each agent’s characteristic, source, modification, experimental manipulation, etc.? Again, it would then just be easier to attach a PDF of the entire registration and write ‘See attached’ in the Template as this information is generally captured in detail within the IBC protocol itself.

3. If required to use the provided Template as proposed, the minutes will be one long continuous table of information. Posting a PDF version of minutes to a public-facing website requires adherence to ADA requirements for the document. Making tables that cross multiple pages ADA compliant is a challenging, adding significant administrative burden to the requirement of posting the minutes immediately after they are approved.
4. If incidents reported to the IBC committee are to be made public, what guidance will be provided on reporting procedures to ensure this reporting does not violate the security and biosafety oversight requirements outlined by the CDC and APHIS Federal Select Agent Program policies. Federal oversight is applied to these facilities due to the nature of the work conducted and the risks associated with this work. Public information would increase security risks for personnel working in these Select Agent facilities and increase potential attacks (cyber or physical) on these facilities, opening institutions to increased risks and increased security burdens.
5. The draft emphasizes public transparency and proposes public disclosure of approved lower-containment determinations/ approvals, incident reports, and meeting minutes. In an era where artificial intelligence and automated data-scraping tools can accumulate institutional information, research related public disclosure may create acute biosecurity vulnerabilities, physical security risks, and exposure of intellectual property. Recommendation: a) Establish clear redaction procedures and legal protections to ensure that confidential business information, personally identifiable information (PII), and sensitive details about facility infrastructure are protected before any documents are made publicly available. b) Ensure public transparency rules follow standard FOIA exemptions so that sensitive security plans and infrastructure details remain protected from public disclosure.

6. Other feedback relevant to this resource: 1. Refine the definition of a reportable incident and provide clearer thresholds for reporting to support a risk-based, consistent approach across institutions.
2. Provide a list of risk groups for all wild type pathogens that fall under the scope of the policy.
3. Provide a list of toxins that would fall under the scope of the policy.
4. We feel like there is an inadequate transition window and lack of federal resource support. The policy requires all existing and new awards to comply within six months of its final publication. This is a very short timeframe, considering that institutions will need to update their standard operating procedures, revise internal policies, modify electronic protocol management systems, and train hundreds of researchers. On top of these challenges, no federal grants or financial support are available to help institutions strengthen or expand their oversight programs within the Division of Research, Sponsored Programs, or Environmental Health and Safety (EHS) programs to meet the new requirements. Recommendation: a) Allow 12 to 24 months for institutions to meet the new requirements, using a gradual rollout that starts with a voluntary pilot program. b) Provide federal grants, ready-to-use templates, and technical support to help underfunded institutions develop the necessary systems for tracking occupational health and biosafety requirements.

485. Syneos Health

I am responding: On behalf of an organization

Name:

Name of Organization: Syneos Health

Type of Organization: Other

Type of Organization - Other: Clinical Research Organization

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Syneos Health is a leading fully integrated biopharmaceutical solutions organization built to accelerate customer success. We translate unique clinical, medical affairs and commercial insights into outcomes to address modern market realities. Together we share insights, use the latest technologies and apply advanced business practices to speed our customers' delivery of important therapies to patients. As a clinical research organization, Syneos Health supports sponsors across clinical development by helping design and operationalize studies, select and activate research sites, coordinate with investigators and institutional review functions, manage investigational products and study procedures, monitor trial conduct, and support safety and regulatory reporting. These activities frequently involve multicenter and global studies conducted across academic, hospital, community, and independent research settings, including trials of biologics, genetically modified products, live biotherapeutics, and other modalities that may fall within the draft policy. We are commenting because the policy's definitions, applicability criteria, review pathways, reporting obligations, and implementation requirements will directly affect site feasibility and activation, institutional coordination, study timelines, patient enrollment and access, and the consistent conduct of clinical research. Our perspective is intended to help NIH establish a scientifically grounded, risk-proportionate, and operationally workable framework that protects participants, clinical personnel, communities, and the environment without imposing unnecessary barriers to research.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Product-scope definitions should be sufficiently precise to avoid confusion and inconsistent interpretation of review and implementation requirements.

NIH should define the evidence needed to establish that a product is capable of shedding, replicating, or integrating. Applicability determinations should be grounded in scientifically justified biological hazards and credible exposure pathways rather than therapeutic modality alone, so that oversight remains proportionate to the actual risks of the investigational product and associated research activities. In particular, detection of noninfectious product material should be distinguished from a credible exposure or transmission hazard. The term "higher risk manipulations" should reflect the biological hazard, exposure pathway, and available controls.

Clinical examples should clearly identify the product modalities covered by the policy, including purified recombinant proteins and monoclonal antibodies, transiently modified cells, nonintegrating nucleic acid products, live biotherapeutics (including live vaccines), and approved products used in research. NIH should clarify that manufacture using genetically modified cells, including commonly used production cell lines such as CHO cells, does not, by itself, bring clinical administration of a purified protein or monoclonal antibody within scope. Similarly, potential therapeutic adverse effects should not automatically classify a protein as a toxin for biosafety oversight.

NIH should also clarify institutional applicability across affiliated hospitals, independent investigator practices, research networks, and non-U.S. sites receiving NIH funding, including sites in Canada. A standardized applicability checklist and a searchable, regularly updated mechanism for verifying which institutions are subject to the policy by virtue of NIH funding would reduce repeated interpretation, support consistent decisions across sites participating in the same trial, and allow sponsors and CROs to plan startup timelines accurately.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Syneos Health supports oversight proportionate to the product, procedures, and credible biosafety risks. The framework should make clinical trial conduct easier rather than more cumbersome so that sites can start efficiently, patients can enroll promptly, and studies can be completed without avoidable delay. NIH should establish distinct tiers of review and submission requirements based on product-risk categories. Well-characterized products with negligible transmission or exposure risk should be eligible for delegated review under defined criteria, with escalation to the full IBC when material risk is identified.

NIH should expressly permit a qualified central IBC to perform a shared product and protocol assessment for multicenter trials. Participating institutions should retain responsibility for local facilities, personnel, handling procedures, waste management, and emergency response. A common sponsor-provided biosafety dossier, supplemented by a concise site-specific assessment, would reduce duplication while preserving local accountability. We also suggest to have a standardize IBC questionnaire as well for the study application.

Where NIH has established an applicable containment determination, other institutions should be able to reference that determination, subject to confirmation that the product and conditions are comparable. Repeated assessment of the same scientific question should be minimized.

The final policy should distinguish amendments affecting the biosafety assessment from administrative, protocol-management, product-management, or clinical changes without biosafety implications. Sites should be able to document through a proportionate process that a change does not require further IBC review.

NIH should clearly reconcile the respective responsibilities and scope of FDA and NIH review and explain how the provision concerning oversight by another federal agency interacts with institutional IBC requirements.

Parallel review across IBC, IRB, pharmacy, infection prevention, occupational health, FDA, and local

authorities should be supported and expected where feasible, rather than allowing dependent or sequential review steps to create avoidable startup delays.

We welcome the provision allowing IBC oversight to conclude after the final dose, subject to the biosafety assessment. NIH should establish consistent closure criteria addressing remaining shedding precautions, specimen handling, and other exposure risks. The policy should explicitly recognize that biosafety risk may change substantially across the clinical trial lifecycle: risks associated with investigational product preparation and administration may differ from those during clinical monitoring or long-term follow-up. Oversight requirements should reflect the activities and credible exposure risks remaining at each stage, and long-term clinical follow-up alone should not require continued IBC oversight once relevant biosafety activities and risks have ended.

For studies requiring continued oversight, NIH should permit a focused, low-effort renewal process comparable to proportionate IRB continuing review when the product, procedures, and risk profile remain unchanged, rather than automatically requiring a complete de novo submission every three years. De novo review would add cost and burden and could disrupt trials at different stages of conduct and participant follow-up without a corresponding biosafety benefit.

3. Continued utility of Risk Groups: No comment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): For institutions participating voluntarily, NIH should provide accessible tools, role-specific training, technical assistance, standardized procedures, and external IBC options. Implementation should not inadvertently restrict research to large academic centers. Clear pathways and practical access to external expertise would help qualified smaller and community research sites offer clinical research as a care option, particularly where patients are geographically dispersed or have limited access to specialized academic centers, while avoiding slower enrollment and disproportionate administrative burden.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: For public disclosure, NIH should permit a standardized safety summary identifying the event, relevant risk, response, and corrective actions. Clear guidance and data-protection mechanisms should protect personal, proprietary, confidential product, and security-sensitive information so that disclosure requirements do not dissuade sponsors from conducting clinical trials in the United States. Lower-risk, locally managed incidents without material public-health implications should not routinely require individual public reports where aggregate reporting would provide comparable public benefit.

For rapid incident reporting, NIH should define the responsible institutional official, start the 24-hour notification clock when that official has sufficient information to determine that the event may meet reporting criteria, specify the minimum information required initially, and clarify expectations when reportability is uncertain. Institutions should take immediate protective action while determining reportability, and a brief preliminary notification should be acceptable while an investigation continues. NIH should distinguish urgent biosafety events from administrative deficiencies without an immediate safety consequence and establish proportionate response expectations.

NIH should clarify the relationship between biosafety incident reporting, clinical safety reporting, and

protocol deviation management. For issues affecting multiple sites, coordinated reporting with site-specific supplements should be permitted to avoid duplicative reports while preserving each institution's responsibility for its local response. Public documentation and rapid reporting may require new contractual and operational interfaces among sponsors, CROs, sites, and external IBCs; NIH should be aware that these requirements will have resulting costs and implementation burden that impacts sites, sponsors, and even NIH resource demand.

Transparency requirements should permit standardized public summaries while protecting proprietary, personal, and security-sensitive information. Minor incidents without material public-health implications should not require individual public posting. Requirements should not inadvertently discourage reporting, deter sponsors from conducting U.S. trials, create inconsistent institutional implementation, or add burdens that delay site activation and patient enrollment without improving safety.

The meeting-minutes template should permit concise documentation of delegated, expedited, reliance-based, renewal, and closure determinations. It should capture the rationale for the biosafety decision and any site-specific conditions without requiring repetition of product-level information already contained in a reusable biosafety dossier.

NIH should provide completed examples for common clinical scenarios and training on consistent use of both templates, including examples applicable to smaller and community sites. Template instructions should also identify appropriate protections for proprietary, personal, and security-sensitive information and support standardized public summaries rather than disclosure of confidential product details.

6. Other feedback relevant to this resource: Syneos Health recommends a transition period longer than 12 months following publication of the final policy and all essential implementation materials, with phased implementation where appropriate. Existing approvals and ongoing trials should be grandfathered until scheduled review unless a material biosafety concern warrants earlier reassessment. A longer transition is needed to prevent a review bottleneck and allow sites and IBCs sufficient time to augment staffing, establish processes, and complete training. Administrative transition should not unnecessarily interrupt participant dosing, enrollment, or follow-up.
NIH should anticipate for how federal and institutional reviewer bandwidth will be increased to accommodate the additional workload created by the policy's expanded scope.

Priority implementation resources should include clear rollout communications and standardized training designed to prevent misinterpretation and inconsistent implementation across institutions, for example:
• A clinical applicability decision tree and product-specific examples.
• Standard submission requirements and a reusable product-level biosafety dossier.
• Criteria for delegated review, amendment assessment, renewal, and closure.
• Model reliance agreements and responsibilities for central IBC arrangements.
• Incident-reporting decision tools and public-disclosure guidance.
• Training tailored to investigators, research coordinators, pharmacy personnel, and community sites.

NIH should evaluate how from the broader R&D and clinical trial planning perspectives, this policy evaluation should consider how these IBC policies, will in part influence the country/site selection and

patient access aspects of trial conduct. Notably, the assessment should specifically monitor whether the policy concentrates research in large academic centers or unintentionally encourages sponsors to move early-phase trials outside the United States. A scientifically proportionate and consistently implemented framework would help preserve U.S. participation in innovative clinical trials while ensuring that expanded oversight delivers meaningful biosafety benefits.

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious diseases and cell & gene therapy

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: While the intent and objectives of the proposed policy are appreciated, the policy would benefit from greater clarity and precision in its definitions, scope, and application. Several provisions appear open to interpretation, which may lead to inconsistent implementation across institutions and create uncertainty regarding oversight responsibilities. It is recommended that the policy provide more explicit definitions of biohazards for the purposes of oversight, clarify the criteria for determining which activities fall within its scope, and address any potential gaps or ambiguities in oversight. These refinements would promote consistent interpretation and implementation, minimize the risk of misinterpretation, and ensure that the policy achieves its intended objectives effectively.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The proposed tiered oversight approach should be carefully calibrated to risk while ensuring clear lines of authority, accountability, and responsibility for administering institutional biosafety programs. The additional administrative and oversight requirements outlined in the policy may place a disproportionate burden on smaller universities and research institutions, particularly those without a dedicated Environmental Health and Safety (EHS) office or a Biosafety Officer (BSO). These requirements may also discourage participation by Institutional Biosafety Committee (IBC) members due to the increased workload and administrative responsibilities. Maintaining databases and fulfilling additional reporting and documentation requirements could further strain institutions with limited resources.

The Biosafety Officer is a cornerstone of an effective institutional biosafety program. Therefore, appointing a qualified BSO should be a mandatory requirement for all NIH-funded institutions conducting research involving biohazards, rather than a requirement limited to institutions operating BSL-3 facilities. Since a substantial proportion of life sciences research involving biohazards is conducted at BSL-2, limiting the requirement to institutions with BSL-3 programs leaves a significant gap in biosafety oversight.

Furthermore, assigning responsibility to the BSO without providing commensurate authority, institutional support, adequate resources, and a clear reporting structure may undermine the

effectiveness of the biosafety program. The policy should explicitly define the BSO's authority, responsibilities, and relationship with institutional leadership, the IBC, and other relevant offices. It should also clarify who within the institution is responsible for reporting biosafety incidents and ensuring regulatory compliance, recognizing that the BSO's operational role may not include the authority to report directly on behalf of the institution.

Finally, institutions should be required to demonstrate that they have an adequately resourced and effectively supported biosafety program, including qualified personnel with clearly defined authority and responsibilities, before an NIH award is issued. The policy should also incorporate a risk-proportionate implementation framework that accounts for institutional size, research activities, and available resources while maintaining appropriate standards of biosafety oversight. These measures would strengthen accountability, address gaps in oversight, and support consistent implementation without imposing disproportionate administrative burdens on smaller institutions.

3. Continued utility of Risk Groups: Risk Groups (RGs) can serve as a useful starting point for risk assessment; however, they should be considered a baseline rather than a definitive determinant of the required level of biocontainment. The appropriate containment level should be established through a comprehensive, evidence-based risk assessment that considers the characteristics of the biological agent, the nature and purpose of any genetic modifications, the experimental procedures, potential exposure routes, and the best available scientific information. The expertise and judgment of the Institutional Biosafety Committee (IBC) should play a central role in this process.

However, many IBCs, particularly at smaller institutions, may lack the specialized expertise and experience needed to assess complex or emerging biological risks independently. Therefore, NIH and FDA should provide clear guidance, technical assistance, training, and sustained outreach to help institutions apply the policy consistently and appropriately. This support is especially important when assessing genetically modified agents for which existing Risk Group classifications may not adequately reflect the risks associated with the proposed research.

Furthermore, communication regarding the policy should be led directly by relevant federal staff and policy makers, rather than relying primarily on contractors. Institutions need opportunities to hear the policy's rationale, interpretation, and implementation expectations directly from the federal officials responsible for developing and administering it. Direct engagement would improve transparency, facilitate meaningful dialogue, and enable institutions to obtain authoritative clarification on complex or ambiguous provisions.

Finally, the Biosafety in Microbiological and Biomedical Laboratories (BMBL) should be reviewed and updated regularly to reflect advances in life sciences research, emerging technologies, and evolving understanding of biological risks. Keeping the BMBL current, alongside accessible federal guidance and technical support, would help ensure that risk assessments and containment decisions remain scientifically sound, proportionate to the actual risks, and consistently applied across institutions.

There is also concern that reporting potential issues involving gain-of-function research, particularly those that may pose significant biological risks, could create reputational concerns for institutions and add substantial administrative burdens. Without clear, consistent, and well-defined reporting

procedures, institutions may face uncertainty regarding what must be reported, when reporting is required, and how such information will be handled. The policy should establish a clear, streamlined, and transparent process for identifying, evaluating, and reporting potential concerns, with well-defined reporting thresholds, responsibilities, and timelines. It should also ensure appropriate confidentiality and consistent handling of reported information to minimize unnecessary reputational concerns while maintaining accountability and public trust. A proportionate, straightforward process would help institutions address potential risks promptly and responsibly without creating unnecessary administrative complexity or discouraging the reporting of legitimate biosafety concerns.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): A major concern regarding voluntary compliance is the lack of clarity about the applicability of the policy to research supported indirectly through NIH funding. For example, if an academic institution subcontracts or collaborates with a contract research organization (CRO) using a portion of an NIH-funded award, it is unclear whether and under what circumstances the policy would apply to the CRO, particularly when the CRO does not receive funding directly from NIH. Such ambiguities have persisted in the interpretation and implementation of the NIH Guidelines, highlighting the need for explicit, practical, and authoritative guidance. Institutions and research partners need clear definitions of the entities, activities, and funding arrangements covered by the policy, along with transparent mechanisms for resolving questions about applicability. These requirements should be clearly articulated in the policy itself rather than left to interpretation, as the absence of explicit provisions may result in inconsistent implementation and significant gaps in oversight.

Another important concern is the application of the policy to small biotechnology companies and other research organizations that may lack formal biosafety oversight structures or adequate institutional resources. Voluntary compliance alone may not be sufficient to ensure consistent and responsible oversight across these entities. The policy should therefore establish clear expectations and provide practical guidance, technical assistance, and scalable oversight mechanisms that accommodate organizations of different sizes and capacities without compromising biosafety standards.

Ultimately, for the policy to achieve its intended objectives, its scope and implementation should extend beyond research directly funded by NIH, where appropriate, through coordinated adoption and harmonization across other relevant federal agencies, including the FDA and Department of Defense (DOD). A consistent, government-wide approach would help address gaps arising from differences in funding mechanisms, subcontracting arrangements, and agency-specific requirements. Without clear applicability criteria, effective interagency coordination, and enforceable oversight expectations, the policy risks creating a fragmented system in which similar research activities are subject to different standards depending on the funding source or institutional affiliation.

Similar to the ClinicalTrials.gov registration and reporting framework, which applies to certain clinical trials regardless of whether they are NIH-funded, a comparable mandatory reporting and registration mechanism should be established for relevant biotechnology research involving potential biological risks. Such a requirement should apply to biotechnology companies, contract research organizations (CROs), and contract development and manufacturing organizations (CDMOs), irrespective of their direct funding source. A centralized database would improve transparency, facilitate consistent oversight, and help prevent gaps in biosafety accountability across the research and development landscape. The policy

should clearly define the research activities subject to registration, the information to be reported, the responsible parties, and the reporting timelines. Appropriate safeguards should also be established to protect confidential business information and sensitive research details while ensuring that relevant authorities have access to the information needed for effective oversight. A mandatory, streamlined, and consistently enforced reporting framework would strengthen biosafety governance beyond the scope of federally funded research alone.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The Draft Incident Reporting and Draft Meeting Minutes Templates require greater clarity and more detailed instructions to ensure consistent implementation across institutions. For incident reporting, the policy must explicitly define what constitutes a reportable incident, who is responsible for submitting the report, to whom it must be submitted, and the applicable reporting timelines. A strict 24-hour reporting deadline may impose a substantial administrative burden, particularly on smaller institutions with limited biosafety personnel and resources. Incident assessment often requires preliminary fact-finding, consultation with research personnel, review by the Institutional Biosafety Committee (IBC), and coordination with institutional officials. These activities may not be feasible within 24 hours.

The policy should therefore clearly distinguish between an initial notification and a comprehensive incident report. For example, an initial notification could be required within 24 hours of identifying a qualifying incident, with a more detailed report submitted within a clearly defined subsequent period after an appropriate investigation has been conducted. The policy should specify the minimum information required in the initial notification, the additional details expected in the full report, and the circumstances under which updates or extensions may be appropriate. A proportionate reporting framework should also account for institutional capacity while ensuring that significant biosafety concerns are communicated promptly and addressed effectively.

Another important concern is the potential public disclosure of information contained in incident reports. If institutions perceive that preliminary or incomplete reports could be publicly released without adequate context, they may be less forthcoming in reporting incidents, potentially undermining the primary objective of the policy. The policy should clearly explain how incident reports will be handled, who will have access to them, and under what circumstances information may be disclosed publicly. It should also establish transparent procedures for protecting confidential, sensitive, and preliminary investigative information, consistent with applicable disclosure requirements. These safeguards should encourage timely, accurate, and complete reporting rather than inadvertently discourage it.

Similarly, the Draft Meeting Minutes Template should include explicit instructions regarding the information that must be documented and the information that may be redacted before submission or public release. The policy should specify the applicable criteria for redaction and provide numerous practical examples addressing confidential business information, proprietary research details, sensitive biological information, personnel information, and preliminary discussions that could be misinterpreted without appropriate context. It should also clarify the distinction between information that must be retained in official institutional records and information that may be redacted from versions submitted to federal agencies or made publicly available.

Overall, both templates should be accompanied by detailed instructions, illustrative examples, and

standardized procedures to minimize ambiguity and administrative burden. These requirements should be practical for institutions of varying sizes and resources while preserving transparency, accountability, and the timely reporting of significant biosafety concerns.

6. Other feedback relevant to this resource: Many institutions may not be adequately prepared to implement the proposed policy within the anticipated timeframe, particularly given the need for greater clarity in several of its provisions. Institutions will require sufficient time to interpret the requirements, assess existing biosafety infrastructure, identify resource gaps, establish appropriate reporting mechanisms, and develop internal procedures. NIH should consider extending the implementation timeline and providing a phased approach that allows institutions to prepare adequately before compliance becomes mandatory.

Effective implementation also requires direct communication with institutional leadership and administrative offices that have the authority to allocate resources and establish institutional priorities. Currently, information about the draft policy often flows through multiple administrative levels, from the Biosafety Officer (BSO) to the Head of Environmental Health and Safety (EHS), and subsequently to the Office of the Vice President for Research (VPR). This communication pathway may delay awareness and leave biosafety personnel responsible for implementing requirements without the institutional authority or resources necessary to do so effectively. NIH should therefore communicate policy requirements, implementation timelines, and institutional expectations directly to the VPR, Office of Sponsored Programs, and other relevant institutional leaders, while ensuring that BSOs and biosafety program personnel remain closely involved in implementation planning.

NIH should also consider providing dedicated financial and technical resources to support the development, strengthening, and implementation of institutional biosafety programs. Additional requirements for reporting, documentation, database maintenance, committee coordination, and incident investigation will increase the workload of existing biosafety personnel. Without additional staffing and institutional support, these responsibilities risk contributing to staff burnout and weakening the effectiveness of existing biosafety programs. Implementation resources should be proportionate to institutional size, research activities, and available infrastructure, with consideration given to smaller universities and institutions with limited administrative capacity.

Another area requiring additional guidance is coordination among Institutional Biosafety Committees (IBCs), Institutional Animal Care and Use Committees (IACUCs), and Institutional Review Boards (IRBs). There appears to be considerable uncertainty and resistance regarding the extent of coordination required among these committees. In many institutions, IRBs do not routinely engage with IBCs, potentially creating gaps in the review of research protocols involving biological agents, genetically modified materials, or other biosafety considerations. These coordination challenges may be particularly pronounced at smaller universities and across the biotechnology industry, where dedicated compliance personnel and established mechanisms for inter-committee communication may be limited.

NIH should provide explicit guidance on when and how these committees are expected to communicate, share relevant information, and coordinate their reviews, while respecting their distinct regulatory responsibilities. Practical implementation resources, including sample institutional procedures, workflow diagrams, role definitions, training materials, and case-based examples, would help institutions establish

effective coordination mechanisms.

Overall, successful implementation will require more than issuing policy requirements. NIH should provide clear guidance, direct engagement with institutional leadership, adequate implementation time, targeted financial and technical support, and practical tools for integrating biosafety oversight into existing institutional research governance structures. These measures are essential to ensure consistent implementation, avoid disproportionate burdens on smaller institutions, and maintain sustainable and effective biosafety programs.

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of the policy should focus on biological agents defined as „bacteria, viruses, fungi, or parasites that cause human disease „. Oversight over genetically modified agents and organisms should be separate. Lower risk materials should remain with local oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered review would be helpful by the way the policy is written is rather confusing. Information in multiple sections though overlaps and is contradicting. There should also be exemptions or admin registrations for low level risk material.

3. Continued utility of Risk Groups: Risk groups are useful for hazard communication and material characterization. But risk group along cannot dictate containment levels. Many elements must be taken into account including volume, procedure, expertise, facility access and more.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: A one size fits all template will not work for all institutions. Additionally, many of the terms mentioned in the incident section are vague and impossible to follow. The timing of reporting should also reflect the risk level. 24h time period should not apply to low risk
Incidents

6. Other feedback relevant to this resource: Federal funding will need to accompany this mandate to ensure correct and efficient application of the policy. Fund will be required to update registration systems, oversight programs, training, especially for smaller and low resource institutions

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The scope of the new policy states that it covers all biomedical research; however, the policy is broader than this. The term biomedical may not apply to all types of research that could fall under this list of biohazards, yet as an institution receiving NIH funds, all PIs with research that includes any one of the listed biohazards would fall under the policy regardless of whether their focus is biomedical.

The definition of biohazards is missing some important biohazards that have the potential to be hazardous to human health. The biohazard risk is focused on humans but animal and plant pathogens also have inherent risks to humans either directly or due to the risk they have on the environment that can then impact human health. Having one unified guidance for these risks makes more sense than each institution developing their own policies, which could differ significantly.

Biohazard Number 4 should include not just cells or organisms, but samples that may contain 1,2, or 3 above. Currently, it is not clear how one would evaluate tissue samples or blood samples that could contain contaminating pathogens, or environmental samples likely to contain viruses or pathogens.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The requirement of an NIH petition for determination of minimum biocontainment level for emerging, novel, or zoonotic biological agents for which the RG classification of containment level is not available in the BMBL should be limited to specific circumstances where there is great uncertainty after a standard risk assessment. Many organisms routinely treated as RG1 organisms are highly unlikely to cause disease and this is clear from the risk assessment. Yet, they do not have an official RG classification and/or are not listed in BMBL. This will likely pose a major bottleneck and unnecessary assessment by the NIH. If this requirement for an official determination is kept, the determinations should be housed online in a form that can be updated continuously to remove redundancies in assessments.

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Section IV-2, second bullet – Which risk groups should be clarified. None are listed, but Section IV-3, second bullet lists RG1 so presumably Section IV-2 is referring to RG2 and greater.

Once the policy is implemented, it should include details on how to handle research with current IBC approval. Will these be grandfathered in for the remainder of their approval period (up to 3 years remaining) or will they need to be reassessed within the updated policy? Will minor changes to the project require full reassessment with the updated policy or could these also be grandfathered in?

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Infectious disease control

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: We welcome NIH's emphasis on layered mitigation. As a developer of UV-C disinfection technology, and seeing how efficacious it can be, we offer three recommendations for the final policy:
1. Recognize UV-C as an engineering control. List room-air and room-surface UV-C disinfection among the examples of facility-based mitigation, alongside ventilation, decontamination systems and biosafety cabinets, especially for aerosol-generating BSL-2 work and BSL-3 suites.
2. Evaluate on performance, not technology type. Give IBCs and biosafety officers guidance on criteria such as:
equivalent clean airflow (as in ASHRAE Standard 241);
-independent efficacy testing;
-recognized safety certification;
-interlocks for whole-room use;
-occupant exposure within ACGIH limits when PPE is not worn.
3. Record the exposure route. Ask that incident reports record the likely route of exposure, to build a national evidence base on aerosol-related lab-acquired infections.

Why this matters
1. Aerosols outside the cabinet are the gap. Lab-acquired infections may come from aerosol exposures that go unnoticed. Pathogen aerosols can be generated outside the biosafety cabinet, during

centrifugation, pipetting, spills and opening vessels. At BSL-2, open-bench aerosols are protected only by general ventilation.
2. During work, UV-C stays in the upper room. Upper-room UV-C has long been used in healthcare against airborne tuberculosis (NIOSH guidelines). It inactivates airborne organisms continuously while staff are present. It adds equivalent air changes well beyond ventilation alone, at a fraction of the energy cost.
3. Between sessions, UV-C can flood the empty room. After a spill, at day's end or before maintenance, it decontaminates exposed surfaces and air within minutes. It leaves no chemical residue and needs no aeration downtime. Interlocks, door switches and occupancy sensing ensure no one is exposed.
4. In BSL-3 and BSL-4 suites, full PPE widens the options. Where staff wear PPE that covers skin and eyes, as in BSL-4 suit labs, the risk of UV-C exposure is much lower. This allows broader in-room use during work, once it is verified that the PPE blocks UV-C.
5. The technology is ready. Modern UV-C LED systems are instant-on, mercury-free and occupancy-sensed, and can be certified for occupied spaces (UL 8802).

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Overall I agree with the expansion of the policy to include biohazards, but I feel the implementation is lacking from the holistic, risk-based approach to biosafety that was discussed in the initial listening sessions.
1) Plants are not included, leading to a major gap in oversight. While I appreciate the NIH's focus on human health and wellbeing, the departure from the current NIH guidelines which include plant work appears to assume there are no conceivable instances where deleterious modifications to plants/plant pathogens could lead to public safety concerns (e.g., GDMO agricultural crops that select for disease susceptibility, or increased tropism of exotic plant pathogens to agriculturally important crops, etc.). This will ultimately just add to the patchwork of regulations rather than synthesize a cohesive system of biosafety oversight.
2) The second definition of genetic modification is problematic; the clause covering stable genome alterations by passaging, reassortment, or chemical or radiological means would pull a lot of ordinary material into registration. I suggest deleting it or narrowing it to intentional modification meant to produce a harmful effect.
3) The definition of toxin is limited to proteins and peptides. That misses non-protein biological toxins such as lipopolysaccharide (LPS, aka endotoxin) and alkaloid-based toxins like those from poison dart frogs. It also doesn’t clearly distinguish a full holotoxin from a harmless subunit. I would also suggest having a threshold for requiring registration. We currently only require registration of toxins of biological origin with an LD50 <1mg/kg bodyweight demonstrated in a mammalian species - this avoids policy mismatch between registering and reviewing all biological toxins and not reviewing chemical toxins (e.g., nicotine with an LD50 ~3 mg/kg bodyweight).
4) Work currently listed as exempt under III-F of the Guidelines, would no longer be exempt. This would increase administrative burden on research and safety staff.
5) “Low risk transgenes” should be more clearly defined (e.g., not containing oncogenes, clinically relevant antibiotic resistance genes, toxin-encoding genes, etc.)
6) Section IV-2 makes IBC approval a precondition for all in-scope work, including new BSL-2 agents and human source material (HSM) work, which would block a single blood draw or cheek swab until the

protocol has had full committee review, drastically slowing down current process. I would recommend amending language to allow for DMR unless material is either known or suspected to contain adventitious agents, rather than the ambiguous "may contain" language.
7) Public posting of incident reports is likely to adversely affect safety. It is hard enough to get people to report incidents in the lab due to perceived burden of post-incident follow-up. We conducted an informal survey with our researchers and they indicated that they would be much less likely to report if they knew it would be publicly posted for many reasons: PIs pressuring staff (either unintentionally or overtly) not to report; embarrassment, fears that the reports would be weaponized against individual PIs and/or the entire institution given the current political climate. It would also further erode public trust in research institutions by construing them as potentially unsafe or reckless in public opinion. If construction companies were required to report every injury requiring first aid, they would also likely be construed as unsafe. In addition, public transparency must be balanced against the goals and requirements of privacy laws (e.g., HIPAA, state privacy laws, collective bargaining agreements) and other policy concerns (e.g., protection of trade secrets, promoting a just and fair culture of incident reporting). With respect to incident reports, which often contain sensitive personal information, NIH should permit anonymized, aggregated reporting with identifiable information disclosed to appropriate governmental officials only when there is a legitimate need to know (e.g., public health investigation).
8) De novo registration will likely result in some materials being inadvertently omitted, leading to an NIH reportable event. Our current process involves a 3-year renewal in which research staff must attest that research is ongoing and to certify whether each of the registered materials are still in active use, are in cold storage, or have been terminally inactivated and properly disposed of/removed from the lab. Something like this is a better approach than starting from scratch every 3 years.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): NIH expects Funded Institutions to perform these responsibilities for ALL non-NIH funded research within the policy's scope. Yet, the policy contains no mechanism to ensure that institutions are fully reimbursed for costs associated with providing these services. Requiring blanket immediate NIH notification is an additional step/administrative burden and is not risk-based. While it may be justified for some instances (e.g., potential release into community), it is not justified for others (e.g., protocol renewal is submitted 1 day late or the IBC meeting has to be pushed back due to scheduling, causing a protocol to exceed the 3 year approval maximum). NIH should also empower the IBC to provide a re-review/reregistration grace period of up to 90 days to accommodate circumstances in which the IBC cannot complete its review within the specified period (delays due to scheduling conflicts, returned submissions for additional comments, PIs on sabbatical, etc.)

3. Continued utility of Risk Groups: RGs are a starting point of risk assessment. If RG is equated to containment, then there is no mechanism in which containment should be lowered. Keep an established list of both.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): congressional action to create a comprehensive biosafety policy that synthesizes all the disparate areas currently overseen in a patchwork fashion by various agencies, regardless of funding source. NIH is attempting something beyond its true scope, and while admirable, will likely fall short of what is truly needed.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The template for the minutes is embedded into the software platform we use; changing this would be cost-prohibitive, and manually entering into a word document would be a tremendous increase in administrative burden. Incident reporting low risk incidents and injuries is not a risk-based approach and will subvert local safety efforts.

6. Other feedback relevant to this resource: Implementation timeline is much to quick for such sweeping changes. 50 years of established biosafety practices and policy and integrated institutional components can't be repealed and replaced within just 6 months. It would place an undue burden on staff responsible for implementation, especially with no guarantee of additional funding or support and substantial expansion of duties and review.

Uploaded File: Comments-for-NIH-Draft.docx

Description: Comments for NIH Draft

The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I

The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.

Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.

Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment, and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.

Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.

Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.

Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.

Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.

Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.

Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting

relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.
Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C

The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.

Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance, engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule

when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.

Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.

Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.

If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee.

Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.

Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual

institutional biosafety duties for excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Policy Does Not Clearly Reduce Burden for Low-Risk Research

Observation
A stated goal of modernization is reducing unnecessary burden for low-risk activities.

Real-World Implementation Impact
Many activities currently viewed as low risk may still require protocol submission, delegated review, documentation, committee reporting, and public records management.
Investigators may not perceive a meaningful reduction in burden.
Why This Matters
Regulatory credibility is strengthened when oversight requirements are clearly aligned with risk.

Recommendation
NIH should identify additional exemptions, registrations, or administrative review pathways for activities with well-established risk profiles.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: RG1 Materials May Be Subject to Substantial New Oversight

Observation
The policy excludes many wild-type RG1 agents but brings numerous low-risk derivatives and commonly used research materials into scope.

Real-World Implementation Impact
Routine plasmids, transgenic models, viral vectors, and other commonplace tools may become subject to new review and documentation requirements.

Why This Matters
Investigators may experience increased oversight despite minimal changes in actual biosafety risk.

Recommendation
NIH should reassess whether certain routinely used low-risk materials warrant formal oversight.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Clarify Oversight of Well-Characterized Cell Lines
Observation
Well-characterized cell lines receive delegated review despite uncertain linkage to the policy's underlying scope.
Real-World Implementation Impact
Biosafety professionals may struggle to determine which cell lines require review and which are exempt.
Why This Matters
Cell culture research represents a major portion of biomedical research.
Recommendation
NIH should clearly distinguish exempt cell culture, delegated review, and full-review categories.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Facility Responsibilities Should Reflect Actual Operational Control
Observation
The draft places significant responsibility on PIs for facilities and containment systems.
Real-World Implementation Impact
Investigators generally do not control ventilation systems, certification contracts, building infrastructure, or emergency power systems.
PIs may become responsible for functions outside their authority.
Why This Matters
Safety responsibilities are most effective when aligned with operational control.
Recommendation
NIH should distinguish responsibilities among institutions, facilities personnel, biosafety staff, and investigators.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Occupational Health Responsibilities Need Clear Triggers
Observation
The policy references occupational health obligations but does not clearly identify when an OHSP is required.
Real-World Implementation Impact
Biosafety professionals may reach different conclusions regarding when occupational health enrollment is necessary.
Why This Matters
Occupational health programs function best when requirements are predictable and consistently applied.
Recommendation
NIH should establish objective triggers and responsibilities for OHSP implementation.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Animal Hazard Oversight Appears Inconsistent
Observation
Several sections address animal-related risks while other provisions appear to exclude certain animal-only pathogens.
Real-World Implementation Impact
Institutions may struggle to determine which animal studies fall within scope.
Why This Matters
Animal biosafety programs depend upon clear oversight boundaries.
Recommendation
NIH should clarify how animal-specific pathogens fit within the framework.

501. Ericka E. Pearce

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Plant Exclusions and Environmental Oversight Are Not Fully Aligned
Observation
Plants appear largely excluded while environmental considerations remain prominent throughout the draft.
Real-World Implementation Impact
Biosafety professionals may be uncertain when environmental review obligations apply.
Why This Matters
Environmental considerations should align with scope definitions.
Recommendation
NIH should explicitly explain the relationship between plant exclusions and environmental risk assessment.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Biological Agent Definitions Require Revision
Observation
The definition of biological agent appears narrower than how the term is used throughout the policy.
Real-World Implementation Impact
Biosafety professionals may encounter situations where covered activities do not clearly fit within the definition.
Why This Matters
Definitions are foundational to consistent implementation.
Recommendation
NIH should harmonize definitions with policy usage.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

503. University of California San Diego

I am responding: On behalf of an organization

Name: Corinne Peek-Asa

Name of Organization: University of California San Diego

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): UC San Diego conducts cutting-edge biomedical, clinical, environmental and engineering research across the School of Medicine, Skaggs School of Pharmacy and Pharmaceutical Sciences, Scripps Institution of Oceanography, Jacobs School of Engineering, and affiliated health centers.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The Policy, as drafted, states: "The NIH Biosafety Policy covers all biomedical research, in laboratory settings, involving biohazards."

This language is ambiguous regarding how it applies to synthetic biology, computational/in silico design, plants, arthropods, animal pathogens, toxins, and non-infectious materials.

UC San Diego requests examples illustrating scope application to common categories of research. If the intent is to cover all biomedical research involving biological agents, the Policy would substantially expand oversight into historically low-risk activities, increasing administrative burden without a demonstrated biosafety benefit.

We recommend a limiting threshold. One that requires a credible, scientifically plausible risk of causing disease in healthy adult humans under reasonably foreseeable laboratory exposure routes and quantities. We propose the consideration of removing oversight of previously exempt toxins, self-aggregating proteins, genetically modified Risk Group 1 organisms, and other low-risk activities under existing NIH Guidelines.

If non-human health risks are intended to be addressed, we would propose the establishment of a separate, clearly defined threshold for environmental, agricultural, ecological or animal-health consequences rather than incorporating them through open-ended references to "biohazards."

Lastly, the applicability of non-NIH funded research needs to be clarified. As an institution-wide regulation, the Policy imposes compliance obligations on non-NIH work. We propose that the agency limit applicability to NIH-supported research or define clear boundary conditions for affiliates, tenants, leased space, and core facilities.

Numerous terms remain undefined or inconsistently used, including “authorized organizational representative,” “biohazard,” “biohazardous,” “biological toxin protein,” “biosafety officer,” “GDMO,” “primary cells that may be contaminated by adventitious agents,” and “well-characterized cell lines.” Clinical terms such as “shedding,” “replicating,” “integrating,” “higher risk manipulations,” and “product” also require definition.

The term “biological agent” is used inconsistently. The definition referencing bacterial, viral, fungal, or parasitic agents that cause human disease does not encompass “gene drive modified biological agents” or “RG1 wild-type agents.” “Human pathogenic agent” may be more accurate where human disease is specifically intended.

The definition of “toxin” is overly broad and does not describe a toxin. Clarify toxicity characteristics such as LD50/LC50 and whether small molecule toxins are included. The definition of “laboratory research” should be revised to encompass activities that may require biosafety oversight but do not fit BSL/ABSL 1-4, e.g., arthropod containment, clinical research activities, and plants expressing human toxins.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): From the UC San Diego perspective, the strongest answer is to support a tiered oversight framework that preserves institutional risk assessment and calibrates federal involvement to risk. To home in on the federal vs. local suggestion.

Federal role: Set minimum national standards, maintain an authoritative and regularly updated Risk Group classification resource, and publish containment-reduction determinations that can be relied upon across institutions. Provide target NIH review timelines, completeness criteria, and an expedited pathway for urgent public health research. Make determinations and rationales publicly available and searchable.
Local/IBC role: Retain primary authority to conduct research-specific risk assessments and assign or approve containment based on local IBC risk assessment, available engineering and administrative controls, institutional risk acceptance, and internal standards. IBCs should be able to impose more stringent controls when site-specific conditions warrant.
Tiered oversight

Distinguish clearly between activities outside scope, exempt from formal IBC review but subject to institutional documentation, eligible for delegated review, and requiring full IBC review. Provide decision trees and examples.
Expand delegated review for routine low-risk work such as replication-incompetent or non-integrating vectors, reporter-only constructs, cell lines, primary materials, transgenic animals, and low-risk genetically modified organisms, with clear escalation triggers to full IBC review.
Preserve IBC as the primary oversight body with strengthened expertise requirements in biosafety, public health, infectious diseases, and animal research as applicable, and retain the requirement for a Biological Safety Officer for large-scale research.
Risk-proportionate scope

Request a limiting threshold such that covered work must present a credible, scientifically plausible risk of causing disease in healthy adult humans under reasonably foreseeable laboratory exposure routes

and quantities. Reduce scope by removing oversight of toxins, self-aggregating proteins, genetically modified Risk Group 1 organisms, and other low-risk activities previously exempt.
If non-human health risks are addressed, establish a separate, clearly defined threshold for environmental, agricultural, ecological, or animal-health consequences rather than incorporating them via open-ended “biohazard” references.
Implementation

Extend implementation timeline to at least 12 months, provide model templates, risk assessment tools, delegated review templates, incident reporting templates, redaction guidelines, and public meeting minute formats before effective date.
Clarify NIH review process: what constitutes an initial request, whether determinations apply to individual experiments or categories, and scope and applicability of each determination, criteria for renewed review, and documentation for IBCs relying on prior determinations.

3. Continued utility of Risk Groups: The Draft Policy relies heavily on Biosafety in Microbiological and Biomedical Laboratories (BMBL) for agent-specific containment. BMBL does not provide Risk Group classification and lags behind emerging research. Institutions have historically used NIH Guidelines, WHO, Public Health Agency of Canada, and other authorities.

NIH should maintain an authoritative, regularly updated Risk Group classification resource and establish a defined process and frequency for review and updates. Risk Group classification, which describes hazard, should be more strongly distinguised from Containment Level, which describes controls. We agree with the University of California Office of the President that the institutional IBCs should retain authority to assign appropriate biosafety level based on local risk assessment, available controls, and specific research.

There is also a need to clarify the NIH review process and timelines, namely what constitutes an “initial request,” when NIH approval is required, and whether determinations apply to individual experiments or categories of research. Target turnaround times, completeness criteria, and an expedited pathway for urgent public health research need to be established.

Decision trees, a searchable repository of prior determinations, and pre-authorized categories for well-characterized agents, attenuated strains, and replication-defective vectors, should be provided.

The IBC should remain the primary body responsible for research-specific risk assessments and containment determinations. IBC expertise requirements should be strengthened to include biosafety, public health, and infectious diseases, with animal research expertise as applicable.

Activities requiring full IBC review from those eligible for delegated review should be clearly distinguished. Requiring review of all genetically modified cells, viruses, or organisms creates a burden for routine low-risk research, particularly genetically modified arthropods and animals. There is also an inconsistency to resolve between delegated review for transgenic organisms at BSL-1/ABSL-1 and BSL-2 minimum containment for “Gene Drive Modified Organisms.”

We also recommend:

Expanding delegated review criteria for replication-incompetent or non-integrating vectors, reporter-only constructs, cell lines, primary materials, transgenic animals, and low-risk genetically modified organisms, with clear escalation triggers.
Clarifying how exemptions operate, transition expectations, and documentation requirements. Distinguish activities outside scope, exempt from formal IBC review but subject to institutional documentation, and eligible for delegated review.
Providing clarification on the Occupational Health and Safety Plan, including when required, expected elements, and scope of NIH oversight.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): From a UC San Diego perspective, the response should emphasize voluntary adoption of NIH-aligned biosafety standards even for research that falls outside mandatory NIH applicability, and propose concrete mechanisms that encourage uptake without imposing federal mandate.

Core principle UC San Diego supports risk-based, proportionate biosafety oversight and can voluntarily align non-NIH funded research with NIH policy principles to promote consistency, interoperability, and safety culture. Voluntary compliance should be facilitated, not penalized, with clear pathways for institutions to opt-in.

Mechanisms to encourage and accommodate voluntary compliance

Institutional assurance model with opt-in tier Allow institutions to submit a voluntary biosafety assurance covering non-NIH funded work under the same assurance framework. NIH could publish a voluntary assurance template and recognize institutions that elect to apply the Policy institution-wide. UC San Diego could map its existing Institutional Biosafety Committee oversight to that assurance to demonstrate compliance for tenants, core facilities, and affiliates.
Public recognition and streamlined review Provide public listing of institutions that voluntarily adopt the Policy, and grant them reliance benefits such as recognition of delegated review determinations and access to the centralized repository of NIH determinations. This creates reputational incentive without regulatory compulsion.
Model guidance, tools, and templates for non-NIH research Make the guidance documents NIH proposes for mandatory implementation available to all institutions, regardless of funding source: risk assessment templates beyond BMBL, delegated review templates, incident reporting decision trees, redaction guidelines, and standardized IBC training. UC San Diego would benefit from these tools for its non-NIH funded biomedical and synthetic biology work.
Carve-out for affiliates, tenants, leased space, and core facilities Define clear boundary conditions so institutions can voluntarily extend oversight to affiliates and core facilities without triggering duplicative federal enforcement. Allow institutions to document voluntary coverage in their Institutional Assurance and maintain institutional records.
Funding-neutral incentives Encourage funders, journals, and collaborators to recognize voluntary adoption as a marker of robust safety governance. NIH could issue a non-binding statement of best practice endorsing voluntary alignment for non-NIH funded research.
Graduated compliance pathway Accommodate phased voluntary implementation with an extended

timeline beyond the 6-month mandatory window, and allow periodic review intervals based on risk level rather than fixed de novo registration every 3 years.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Comments on the Draft Incident Reporting and Draft Meeting Minutes Templates should focus on risk-proportionate transparency and administrative feasibility. Therefore, we recommend the following in these two areas.

Incident Reporting

Adopt a two-tier framework: NIH-reportable/high-consequence incidents reported to NIH and summarized publicly with standardized redactions; lower-risk incidents, near misses, and anomalies kept institutionally and aggregated in a centralized, de-identified database.
Set clear thresholds distinguishing credible exposure/release pathways from contained anomalies where redundant controls remained effective.
Publish a standardized redaction framework identifying information to withhold: sensitive facility/inventory data, security vulnerabilities, proprietary methods, titles, and personal identifiers.
Allow additional time beyond 24 hours or alternative disclosure for security-sensitive or actively investigated incidents.
Clarify relationships among incident reports, IBC minutes, and Institutional Assurances, including confidentiality/retention when incidents span multiple protocols or grants. Provide a decision tree and target NIH review timelines with completeness criteria.
UC San Diego currently uses EHS Risk Management incident forms for student/visitor and occupational incidents, which can be aligned with biosafety reporting to reduce duplication.

Meeting Minutes

Limit public posting to information necessary for transparency and accountability. Provide flexibility on posting timing based on meeting frequency and administrative capacity.
Permit substantially equivalent formats from institutional electronic systems provided required data elements are captured. Publish a machine-readable list of required fields.
Remove training information from minutes templates; training records are dynamic and may contain PII and are better maintained separately.

6. Other feedback relevant to this resource: There is a need to provide implementation guidance for de novo synthesis of genetic sequences, novel constructs without natural counterparts, and standardized biological parts conferring new properties. It is also mandatory to provide criteria and examples for IBC review, delegated review, or no review.

We also support establishing review triggers and minimum safeguards for AI/LLM-assisted biological design tied to high-consequence properties, narrowly defined to avoid impeding general computational research.

In regard to required guidance documents and resources, we'd like to summarize in order to support consistent implementation. NIH should make the following available before the effective date to ensure clarity, ease burden and streamline compliance:

Comprehensive definitions and examples to assess what falls within the scope of policy
Guidance confirming institutional IBC authority for containment and oversight
Risk group classifications
Templated process to request NIH determination for risk group assessment
Guidance on reliance on posted determinations
Searchable repository of prior determinations
Incident report template and decision tree
Standardized redaction guidance
Machine-readable meeting minutes fields
Risk assessment template beyond BMBL
Guidance on environmental/agricultural/animal/arthropod risks
Decision tree distinguishing scope/exemption/delegated/full review
Delegated review template
Standardized IBC training
Occupational health and safety plan template
AI/LLM and synthetic biology examples and determinations.

Uploaded File: UC-San-Diego-NIH-Response-Biosafety-Policy.docx

Description: Full letter of UC San Diego submission of comments to the Draft NIH Biosafety Policy for Research Involving Biohazards issued August 19, 2026. We applaud several aspects of the Draft Policy, including a simplified review structure and terminology, greater transparency through a public incident database and the addition of delegated review. However, we share the University of California's system-wide concerns articulated by the University of California Office of the President in its thoughtful and detailed response. However, we would like to emphasize a number of priorities for UC San Diego.

Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazard

RE: UC San Diego Comments in Response to NOT-OD-26-112, "Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards"

Dear Sir or Madam:

UC San Diego submits the following comments on the Draft NIH Biosafety Policy for Research Involving Biohazards issued August 19, 2026.

As one of ten University of California campuses, UC San Diego conducts cutting-edge biomedical, clinical and environmental research across the School of Medicine, Skaggs School of Pharmacy and Pharmaceutical Sciences, Scripps Institution of Oceanography, Jacobs School of Engineering, and affiliated health centers.

We receive significant NIH funding and operate Institutional Biosafety Committee oversight consistent with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules.

We applaud several aspects of the Draft Policy, including a simplified review structure and terminology, greater transparency through a public incident database and the addition of delegated review. However, we share the University of California's system-wide concerns articulated by the University of California Office of the President in its thoughtful and detailed response. We would like to emphasize the following priorities for UC San Diego:

1. Define and narrow policy scope to apply oversight proportionate to risk
The Policy, as drafted, states: "The NIH Biosafety Policy covers all biomedical research, in laboratory settings, involving biohazards."

This language is ambiguous regarding how it applies to synthetic biology, computational/in silico design, plants, arthropods, animal pathogens, toxins, and non-infectious materials.

UC San Diego requests examples illustrating scope application to common categories of research. If the intent is to cover all biomedical research involving biological agents, the Policy would substantially expand oversight into historically low-risk activities, increasing administrative burden without a demonstrated biosafety benefit.

We recommend a limiting threshold. One that requires a credible, scientifically plausible risk of causing disease in healthy adult humans under reasonably foreseeable laboratory exposure routes and quantities. We propose the consideration of removing oversight of previously exempt toxins, self-aggregating proteins, genetically modified Risk Group 1 organisms, and other low-risk activities under existing NIH Guidelines.

If non-human health risks are intended to be addressed, we would propose the establishment of a separate, clearly defined threshold for environmental, agricultural, ecological or animal-health consequences rather than incorporating them through open-ended references to "biohazards."

Lastly, the applicability of non-NIH funded research needs to be clarified. As an institution-wide regulation, the Policy imposes compliance obligations on non-NIH work. We propose that the agency limit applicability to NIH-supported research or define clear boundary conditions for affiliates, tenants, leased space, and core facilities.

2. Clarify and standardize definitions

Numerous terms remain undefined or inconsistently used, including "authorized organizational representative," "biohazard," "biohazardous," "biological toxin protein," "biosafety officer," "GDMO," "primary cells that may be contaminated by adventitious agents," and "well-characterized cell lines." Clinical terms such as "shedding," "replicating," "integrating," "higher risk manipulations," and "product" also require definition.

The term "biological agent" is used inconsistently. The definition referencing bacterial, viral, fungal, or parasitic agents that cause human disease does not encompass "gene drive modified biological agents" or "RG1 wild-type agents." "Human pathogenic agent" may be more accurate where human disease is specifically intended.

The definition of "toxin" is overly broad and does not describe a toxin. Clarify toxicity characteristics such as LD50/LC50 and whether small molecule toxins are included. The definition of "laboratory research" should be revised to encompass activities that may require biosafety oversight but do not fit BSL/ABSL 1-4, e.g., arthropod containment, clinical research activities, and plants expressing human toxins.

3. Broaden the reference framework beyond Biosafety in Microbiological and Biomedical Laboratories

The Draft Policy relies heavily on Biosafety in Microbiological and Biomedical Laboratories (BMBL) for agent-specific containment. BMBL does not provide Risk Group classification and lags behind emerging research. Institutions have historically used NIH Guidelines, WHO, Public Health Agency of Canada, and other authorities.

NIH should maintain an authoritative, regularly updated Risk Group classification resource and establish a defined process and frequency for review and updates. Risk Group classification, which describes hazard, should be more strongly distinguised from Containment Level, which describes controls. We agree with the University of California Office of the President that the institutional IBCs should retain authority to assign appropriate biosafety level based on local risk assessment, available controls, and specific research.

There is also a need to clarify the NIH review process and timelines, namely what constitutes an "initial request," when NIH approval is required, and whether determinations apply to individual experiments or categories of research. Target turnaround times, completeness criteria, and an expedited pathway for urgent public health research need to be established.

Decision trees, a searchable repository of prior determinations, and pre-authorized categories for well-characterized agents, attenuated strains, and replication-defective vectors, should be provided.

4. Preserve Institutional Biosafety Committee (IBC) authority and institutional risk assessment

The IBC should remain the primary body responsible for research-specific risk assessments and containment determinations. IBC expertise requirements should be strengthened to include biosafety, public health, and infectious diseases, with animal research expertise as applicable.

Activities requiring full IBC review from those eligible for delegated review should be clearly distinguished. Requiring review of all genetically modified cells, viruses, or organisms creates a burden for routine low-risk research, particularly genetically modified arthropods and animals. There is also an inconsistency to resolve between delegated review for transgenic organisms at BSL-1/ABSL-1 and BSL-2 minimum containment for "Gene Drive Modified Organisms."

We also recommend:

- Expanding delegated review criteria for replication-incompetent or non-integrating vectors, reporter-only constructs, cell lines, primary materials, transgenic animals, and low-risk genetically modified organisms, with clear escalation triggers.

- Clarifying how exemptions operate, transition expectations, and documentation requirements. Distinguish activities outside scope, exempt from formal IBC review but subject to institutional documentation, and eligible for delegated review.
- Providing clarification on the Occupational Health and Safety Plan, including when required, expected elements, and scope of NIH oversight.

5. Revise public disclosure requirements

Public posting of IBC minutes, incident reports, and Institutional Assurances without uniform redaction standards risks security, privacy, proprietary, and reputational harm. NIH should publish a standardized redaction framework identifying information to be withheld, including sensitive facility or inventory information, security vulnerabilities, proprietary methods, and personal identifiers.

We suggest replacing institution-by-institution posting of all incident reports with a two-tier framework: NIH-reportable and high-consequence incidents reported to NIH and summarized publicly with standardized redactions. Lower-risk incidents, near misses, and anomalies should be maintained institutionally and aggregated in a centralized, de-identified database.

It is necessary to establishing clear reporting thresholds to distinguishing credible exposure or release pathways from contained anomalies. There is also a need to clarify relationships among incident reports, IBC minutes, and Institutional Assurances and to provide additional time beyond 24 hours for security-sensitive incidents or active investigations.

A continuity mechanism should be included, such as an extension during Institutional Assurance renewal review, to prevent administrative delays from interrupting compliant research.

6. Clarify containment and oversight for GDMO and environmental risks

Oversight authority for genetically modified plants must be clarified and a justification provided for exclusions. Genetically modified plants may express toxins and impact native varieties, arthropod communities, or soil microbiota.

For gene drive modified arthropods, BSL-2 minimum containment is a poor fit; the principal hazard is environmental escape, not personnel infection. Human health biocontainment must be distinguished from environmental containment and arthropod containment use levels where appropriate.

If environmental, agricultural, and animal health risks are determined to be within scope, they must be governed under the separate threshold described above rather than through an open-ended interpretation of “biohazard.”

7. Reduce administrative burden and eliminate redundancy

The implementation timeline should be extended from 6 months to a minimum of 12 months to reduce unnecessary burden. It is also essential to clarify how the institutional biosafety assurance complements existing NIH compliance certifications to avoid duplication. Providing model templates and electronic resources ahead of the effective date would be helpful.

The records-retention requirements should be specific to IBC oversight rather than tied to award financial retention. Allowing institutions to establish periodic review intervals based on risk level rather than requiring de novo IBC registration every 3 years would be appropriate.

Among other administrative concerns:

- Public posting should be limited to information necessary for transparency.
- The timing requirements should be modified for meeting minutes posting to allow flexibility based on meeting frequency.
- Substantially equivalent formats should be permitted for minutes and incident reports from institutional electronic systems and NIH should publish a machine-readable list of required fields to standardize content while minimizing duplicative work.
- Standardized IBC member training should be created and published
- The relationship of OSHA, Federal Select Agent Program, FDA, and the July 2026 USG Policy for Stopping High-Risk Life Sciences Research should be clarified to avoid duplication and conflicting determinations.

8. Establish clear biosafety oversight for clinical research

The IBC role in clinical research should complement, not duplicate, FDA and human subjects protections and, therefore, needs further clarification. Defining specific biosafety issues remaining within IBC oversight is necessary, as well as clear endpoints for oversight, such as last administration of an investigational product and an evidence-based shedding monitoring window.

Several clinical definitions also need to be provided for universal definitions of “shedding,” “replicating,” “integrating,” “higher risk manipulations,” and “product.” Adopting a hierarchy of

controls approach with standard precautions as baseline and transmission-based precautions based on hazard characteristics should be a priority.

9. Provide guidance for synthetic biology and AI-assisted research

There is a need to provide implementation guidance for de novo synthesis of genetic sequences, novel constructs without natural counterparts, and standardized biological parts conferring new properties. It is also mandatory to provide criteria and examples for IBC review, delegated review, or no review.

We also support establishing review triggers and minimum safeguards for AI/LLM-assisted biological design tied to high-consequence properties, narrowly defined to avoid impeding general computational research.

10. Required guidance documents and resources

To summarize and to support consistent implementation, NIH should make the following available before the effective date to ensure clarity, ease burden and streamline compliance:

- Comprehensive definitions and examples to assess what falls within the scope of policy
- Guidance confirming institutional IBC authority for containment and oversight
- Risk group classifications
- Templated process to request NIH determination for risk group assessment
- Guidance on reliance on posted determinations
- Searchable repository of prior determinations
- Incident report template and decision tree
- Standardized redaction guidance
- Machine-readable meeting minutes fields
- Risk assessment template beyond BMBL
- Guidance on environmental/agricultural/animal/arthropod risks
- Decision tree distinguishing scope/exemption/delegated/full review
- Delegated review template
- Standardized IBC training
- Occupational health and safety plan template
- AI/LLM and synthetic biology examples and determinations.

Thank you for the opportunity to comment. UC San Diego looks forward to continued engagement on this important Policy.

Sincerely,
Corinne Peek-Asa
Vice Chancellor for Research and Innovation
University of California, San Diego

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): arlington

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The Term "Biohazard" Should Be Defined
Observation
The draft repeatedly references biohazards but does not define the term.
Real-World Implementation Impact
Biosafety professionals may develop different interpretations of what activities fall within scope.
Why This Matters
Undefined regulatory terms often become sources of implementation variability.
Recommendation
NIH should add a formal definition.

505. Ericka E. Pearce

I am responding: On behalf of myself

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): arlington

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Public Reporting May Discourage Near-Miss Reporting
Observation
The policy promotes both public reporting and confidential reporting mechanisms.
Real-World Implementation Impact
Personnel may be less willing to report minor events if they believe information may become publicly disclosed.
Why This Matters
Strong reporting cultures depend on trust and psychological safety.
Recommendation
NIH should clearly separate near-miss reporting from publicly posted incidents.

Incident Reporting Thresholds Require Clarification
Observation
The draft relies heavily on terms such as "any," "potential," and "significant."
Real-World Implementation Impact
These terms may trigger different reporting decisions for identical events.
Why This Matters
Consistency is difficult when thresholds are not defined.
Recommendation
Provide definitions, examples, and reporting criteria.

Public Reports Need Standardized Context
Observation
Incident reports may be publicly posted without clear contextual expectations.
Real-World Implementation Impact
Events with vastly different risk profiles may appear equivalent to external audiences.
Why This Matters

Transparency is most effective when accurate context is provided.
Recommendation
Require standardized summaries describing the nature and outcome of incidents.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: Response-to-the-Draft-NIH-Biosafety-Policy-for-Research-Involving-Biohazards.docx

Response to the Draft NIH Biosafety Policy for Research Involving Biohazards

While we agree with the intent of the NIH's draft policy to expand their risk-based framework beyond the current policy for recombinant and synthetic nucleic acid research, we do not agree that the NIH's policies should govern **ALL** research undertaken at Universities within Australia "… **any research conducted at or sponsored by the institution, irrespective of the source of funding, shall comply with this Policy"** as Australia already has legislation, guidelines and laboratory standards that govern research in Australia.

- Both federal and state-based legislation that encompasses the Gene Technology Scheme (Gene Technology Act and Regulations) which provides a structured risk-based approval system for genetically modified organisms (GMOs) and gene drive modified organism (GDMOs).
- Strong Occupational Health and Safety laws which require all institutions to have systems in place to review and assess risks.
- The NH&MRC which is the main statutory authority of the Australian Government responsible for medical research also has policies, guidelines and codes of conduct which apply to all research.
- Laboratory design and safety standards which include Risk Grouping of microorganism and the appropriate physical containment (PC) facility guidelines which must be followed.

Compliance with Australian legislation is mandatory should take priority over NIH policy guidelines.

The University already has a properly constituted IBC for review of work with genetically modified organisms as required under Gene Technology Scheme. This scheme also included authorisation pathways for high-risk GMOs which requires approval by the IBC as well as the OGTR (Office of the Gene Technology Regulator).

The University already has a biorisk management process which assesses work with wildtype microorganisms (or material likely to contain them). The University does not have any Physical Containment Level 3 (PC3) facilities and therefore no work with Risk Group 3 or above organisms is permitted. All work with Risk Group 2 microorganisms (or material likely to contain them) is approved by the BSO and the Laboratory Biosafety Committee.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: The Phrase "To the Maximum Extent Possible" Is Too Open to Interpretation
Observation
The phrase appears repeatedly throughout transparency provisions.
Real-World Implementation Impact
Institutions will apply different standards regarding disclosure and redaction.
Why This Matters
Consistency requires clearer standards.
Recommendation
Provide explicit disclosure and redaction criteria.

The Repeated Use of "Any" Creates Extremely Broad Reporting Triggers
Observation
The word "any" appears throughout multiple reporting sections.
Real-World Implementation Impact
Institutions may interpret the requirement as encompassing even trivial events.
Why This Matters
Over-reporting may obscure significant incidents.
Recommendation

Differentiate between reportable both to NIH and internally, recordable, and informational events.

The Phrase "Such As" Requires Clarification
Observation
Several reporting sections use illustrative examples.
Real-World Implementation Impact
Biosafety professionals may not know whether examples are exhaustive or merely representative.
Why This Matters
Different interpretations generate inconsistent compliance.
Recommendation
Clarify whether listed examples are illustrative or exclusive.

508. Griffith University

I am responding: On behalf of an organization

Name: Lynette Farquhar

Name of Organization: Griffith University

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Griffith University supports broad, risk-based coverage of relevant biohazards. However, applying the proposed Policy to all relevant research at any institution receiving NIH funding—regardless of funding source or connection to NIH—is disproportionate and extends NIH oversight beyond the funding relationship. Mandatory requirements should be limited to NIH-funded research and activities directly supporting or materially connected to that research. For foreign institutions, NIH should establish an equivalency pathway recognising demonstrably comparable host-country statutory and institutional controls, thereby maintaining effective oversight without creating regulatory gaps or duplicating domestic requirements.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Griffith supports tiered oversight calibrated to the nature, scale and uncertainty of the risk, with federal involvement focused on higher-risk or novel NIH-supported activities and routine oversight undertaken locally. For Australian institutions, "local" oversight should include applicable Australian national regulation and accredited institutional biosafety arrangements. Australia has established IBC-based gene-technology oversight and a statutory scheme governing security-sensitive biological agents. NIH should permit these arrangements to satisfy relevant requirements through a foreign-assurance or equivalency pathway, rather than requiring duplication of US-specific structures and processes.

3. Continued utility of Risk Groups: Griffith does not recommend exclusive reliance on either Risk Groups or Biosafety Levels. The draft Policy itself recognises that RGs describe agent characteristics while BSLs address the containment appropriate to the specific work, and that the two are related but not equivalent. The final Policy should remain outcome-focused and require a comprehensive, activity-specific risk assessment. For foreign institutions, NIH should recognise equivalent domestic terminology, risk-classification and physical-containment frameworks where institutions can demonstrate that these achieve appropriate biosafety outcomes.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary adoption should be clearly distinguished from mandatory extraterritorial application. NIH may encourage organisations outside the Policy's scope to

adopt its principles and commensurate oversight voluntarily, supported by adaptable guidance, model tools and crosswalks to domestic frameworks. Voluntary compliance should not require institutions to reproduce US-specific governance, documentation or terminology. An equivalency pathway would facilitate voluntary alignment while preserving Australian regulatory responsibility for non-NIH research and avoiding the effective extension of mandatory NIH requirements to unrelated activities.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The templates provide useful structure but are highly prescriptive and create substantial administrative, redaction and publication requirements. The incident template requires detailed reporting, root-cause analysis and corrective actions, while the minutes template requires extensive protocol, risk-assessment, attendance and decision information for public posting. NIH-specific templates and public-disclosure requirements should therefore apply only to NIH-funded or materially connected activities. Incident reports and minutes relating solely to non-NIH research should not be subject to NIH publication requirements. NIH should also accept equivalent Australian institutional records, supported where necessary by a concise NIH cover sheet or mapping, rather than requiring duplicate documentation.

6. Other feedback relevant to this resource: NIH should provide dedicated guidance for foreign institutions covering: eligibility and evidence requirements for an equivalency or foreign-assurance pathway; the test for determining when research is materially connected to NIH funding; mapping of NIH requirements to Australian regulatory and containment frameworks; incident-reporting and public-disclosure expectations; and management of conflicting domestic requirements. Guidance should include worked examples for institutions with mixed NIH and non-NIH portfolios, proportionate transition arrangements and mechanisms to avoid duplicate approvals and records. NIH's existing Foreign Animal Welfare Assurance provides a useful model because it recognises applicable host-country laws and acceptable assurance standards for supported activities.

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): arlington

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Synthetic Biology Reviews May Become Overly Conservative
Observation
The policy assumes introduced sequences retain their original function.
Real-World Implementation Impact
Investigators may face containment requirements disproportionate to actual risk.
Why This Matters
Risk assessment should remain evidence-based and proportionate.
Recommendation
Clarify how empirical evidence may modify initial assumptions.

Gene Drive Review Criteria Need Greater Specificity
Observation
The policy references uncertainty and environmental impacts without thresholds.
Real-World Implementation Impact
Biosafety professionals may differ substantially in review expectations.
Why This Matters
National consistency requires clearer criteria.
Recommendation
Provide examples and decision frameworks for evaluating uncertainty and environmental risk.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Overall Assessment and Recommendation
Observation
The transition from a prescriptive framework to a broader risk-based framework is appropriate and forward-looking.
Real-World Implementation Impact
The primary challenge faced by biosafety professionals will be interpreting broad terms, implementing new governance structures, applying novel reporting requirements, and achieving consistency with limited implementation guidance.
Why This Matters
The success of the policy will depend less on the principles it establishes and more on whether biosafety professionals can implement those principles consistently.
Recommendation
NIH should accompany the final policy with:
• Definitions;
• Decision trees;
• FAQs;
• Model governance structures;
• Risk assessment examples;
• Transition guidance;
• Reporting thresholds; and
• Implementation toolkits.
These resources would significantly improve consistency, transparency, and successful implementation across the research enterprise.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

HARVARD MEDICAL SCHOOL | COMMITTEE ON Microbiological Safety

Comment on NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

To Whom It May Concern:

I write on behalf of Harvard University in my capacity as Director of Harvard's IBC (COMS) to submit the following comments in response to the National Institutes of Health (NIH) effort to modernize biosafety oversight and to create a risk-based framework that extends beyond recombinant and synthetic nucleic acid research. We strongly support rigorous biosafety practices in research, though we believe that any final policy would benefit from greater precision in its definitions, clearer boundaries of authority, and additional implementation guidance prior to the finalization.

As a member of the Association of American Universities, COGR, and ABSA International, Harvard generally endorses their comments and recommendations, except as noted below. In general, we support revising the draft policy, allowing an additional comment period, and adopting a phased, 24-month implementation period so institutions can update their policies, training, and oversight systems. We share the associations' concerns about scope, definitions, regulatory clarity, and operational feasibility and offer the following comments to strengthen the proposal.

Policy Scope (Section II). The draft policy seeks to include "all biomedical research, in laboratory settings…involving biohazards…[with] known or potential risk to human health." While the "risk to human health" implies RG2/BSL-2 research and above, other sections of the draft policy expand potential applications to BSL-1 research, naturally occurring mutants of low-risk organisms, environmental samples with "adventitious agents," non-pathogenic recombinant constructs, and toxins not extracted from their natural environments. We urge you to clarify that field research, arthropod containment, and plant containment is outside the scope of the draft policy. Additionally, for biological agents that pose risk to animal health but are not known to cause disease in humans, we urge NIH to define the threshold for review and oversight.

Roles and Responsibilities (Section III). The NIH draft policy requires the review of broadly conceived emerging, novel and zoonotic agents, which will require NIH consultation for routine determinations currently managed by institutional biosafety programs and institutional biosafety committees (IBCs). In addition to tightening these definitions, as recommended elsewhere in this letter, we urge NIH to preserve IBC authority for making containment determinations whenever possible.

NIH should clarify its authority for "determining the appropriate containment level for emerging, novel, or zoonotic biological agents for which the RG classification or containment level is not available in the BMBL." To that end, we recommend that only organisms that meet the definition of RG3/RG4 or BSL-3/BSL-4 research be subject to this requirement; the assignment of containment levels for organisms meeting the definition of RG1 and RG2 should remain within the purview of the IBC. As part of these clarifications, we urge NIH to detail how institutions should manage existing risk assessments for organisms that lack risk group designations or biosafety level recommendations when IBCs have already assigned minimum containment, define the risk group levels referenced in criteria requiring NIH approval of containment, and limit retrospective review to organisms classified as RG3 or RG4, or for research requiring BSL-3 or BSL-4 containment.

The draft policy calls for NIH to publish approved lower-containment determinations for research involving wild-type or genetically modified RG3 or RG4 agents but does not extend this requirement to emerging, novel, zoonotic, or GDMO agents. We recommend including those determinations in a searchable resource similar to the Public Health Agency of Canada's *ePathogen* database. Containment levels established by other federal agencies, such as the Centers for Disease Control and Prevention, should require only notification to NIH for inclusion in the list, not separate NIH approval. NIH should also establish a process for periodically reviewing listed agents against new scientific literature and public health data and publish proposed changes for comment before adoption.

To focus on IBC activities appropriately, we recommend that the final policy establish clear, broad exemptions and expedited review categories for well-characterized, low-hazard work, such as non-pathogenic host strains, well-characterized cell lines, and low-risk inserts. The policy should also specify when delegated review must be escalated to the full committee and clarify when an IBC may assign containment levels and approve research involving agents not listed in the BMBL. Because the agents included in the BMBL vary by edition and may be removed from later editions, the BMBL should serve as a reference rather than the sole basis for determining containment. IBCs should also be permitted to use relevant scientific literature when assigning containment levels for agents that meet RG1 or RG2 criteria.

For research with non-select agent toxins and self-aggregating proteins (not prions), NIH should allow delegated review. (See comments regarding "toxin"-defining criteria and potential removal from scope.) Additionally, the section requiring IBC review and approval before initiation should be narrowed with the addition of the following language in parentheses: "Research with primary cells that may be contaminated [with RG3 or RG4] agents [or agents requiring BSL-3 or BSL-4 containment]."

Additionally, the NIH policy should clarify when delegated review is allowed for "minor amendments to previously IBC approved submissions" vs new projects or projects going through subsequent de novo review. We recommend allowing delegated review for all protocols and amendments not explicitly requiring IBC review and approval before initiation. We also support further clarification of the following language in this section:

- Research with "genetically modified RG1 biological agents" is subject to the policy when wildtype RG1 agents are not. Most recombinant experiments with RG1 organisms are exempted or fall under III-E of the current NIH Guidelines. A common example is cloning or expressing to human/animal genes in non-pathogenic *E. coli* or integration of a fluorescent tag. Since most recombinant experiments with RG1 agents do not elevate risk, we recommend changing to only "genetic modifications in RG1 organisms expected to lead to pathogenicity or production of a toxin capable of negatively impacting human health such that elevated containment is required".
- The policy implies that all research involving plasmids (even outside of an organism) now requires registration. We recommend the following language requiring registration of these systems only when used in organisms or cells: "Research with plasmids or replication-incompetent, non-integrating viral vectors expressing reporter or low-risk transgenes."
- Remove "Research with well-characterized cell lines" from delegated review because the policy covers cell lines only when they include a biohazard (Section IV-3).

Risk Assessment (Sections III, IV, V). The risk group classification provides a starting point for determining containment as it relates to personal and environmental risk, although the BMBL does not include that category. Instead, the current NIH Guidelines act as the reference point for risk group classification. We urge NIH to add a risk group table to the policy and to determine if an agent qualifies as a "biohazard" and a "risk to human health" for inclusion within the policy scope. If retained within the policy, NIH should clarify how toxins and proteins will be classified and specify who holds authority to assign containment for this category and how incidents involving toxins and proteins are to be reported,

given that these agents are handled, shipped, and disposed of as chemicals and are not assigned risk groups or biosafety levels.

We also urge NIH to revisit the synthetic-biology framework and the influenza provision in consultation with the stakeholder community. Although Section V-C appropriately discusses gene function and possible synergy, it emphasizes the highest risk group of source organisms, the percentage of genome contributed by each source, and an assumption that sequences function as they did in their original host. These are not reliable general predictors of biological risk, as their function depends heavily on regulatory, cellular, genomic, and ecological context. Similarly, the influenza provision requires containment to correspond to the source contributing the majority of viral segments. Influenza phenotype is not determined by segment counting. A minority segment or a small number of mutations can affect receptor binding, host adaptation, polymerase activity, tissue tropism, pathogenicity, or transmissibility. For these reasons, we urge that any containment on influenza should be based on the specific construct, phenotype, and protocol.

Emerging, Novel, and Zoonotic Agents (Sections III-B, III-D, IV-1). As drafted, the NIH requirement for containment determinations for emerging, novel, and zoonotic agents – which commonly lack established risk group classifications and biosafety levels – poses a unique challenge for institutions. Many organisms, particularly those used at BSL-1 based on institutional risk assessment determinations, are not listed in the BMBL, making it unclear when NIH review would be required before work could begin. To resolve this ambiguity, and minimize project delays and inconsistent determinations, NIH should develop a national risk group or containment database and publish determinations for agents lacking established containment. That said, it is our strong recommendation that NIH allow IBCs to determine an appropriate containment level based on risk assessment when there is no clear evidence of significant risk to human health and where agents do not meet the definition of RG3-RG4 or require BSL-3 or BSL-4 containment.

Also, the NIH draft policy does not contain a clear distinction between “novel” vs “genetically modified" agents. We recommend either uniting or further separating these definitions and retaining IBC review and approval with few exceptions. NIH should define criteria for their involvement in setting containment based on risks, not simply based on the “agent or organism not existing in nature, [being] deliberately designed, and possibly derived from multiple, different natural or synthetic sources.” Examples would be single-cycle replicon systems that lack structural protein genes or an agent modified to serve as a vaccine candidate.

Incident Report and IBC Provisions (Sections III-B and III-C). While we appreciate and support institutional consistency and transparency, some of the new requirements could substantially increase burden while providing limited risk reduction. In general, we urge NIH to ensure reporting is tiered and risk based, with a clear separation between voluntary learning reports and enforcement systems; limit who may access submitted information that includes security-sensitive, proprietary, clinical, personnel, and reputational information; clarify whether submissions could become subject to disclosure or legal process; publish aggregate lessons learned back to the biosafety community; and, monitor these changes for impacts to safety and de-incentivization in reporting

On the IBC minutes, we recommend that the incident reporting section in the template be sufficient for posting of incidents, with the redaction of PI names and laboratory identifiers, and that the requirement related to the review and inspection reports for every protocol be limited to discussion or notation only when significant deficiencies are noted. We also recommend that non-IBC members be allowed to remain anonymous to ensure continued public participation and engagement.

Further, the policy should confirm if the incident reporting template is to be used for urgent, 24-hour reporting, with the understanding that most sections would be incomplete in an initial report. NIH should provide an IBC vs. NIH authority table for incident reporting (as an example, see Appendix A). The

boundary between institutional handling and NIH notification is currently unclear and spread across narrative text.

Nexus with the Policy for Stopping High Risk Life Sciences Research, While we support NIH's stated intention to develop a more coordinated interagency policy, we are concerned that the draft NIH policy is incongruent with the Policy for the Stopping High Risk Life Sciences Research (High-Risk Policy), with scope and definitions that differ significantly. At many institutions, including Harvard, IBCs serve as the primary reviewing body for biological research and the principal referral mechanism to Institutional Review Entities (IRE) for assessment of dangerous gain of function (DGOF) research. Because of this relationship, the IBC or a subset of IBC members may also act as the IRE. Additionally, agencies and institutions attempting to implement the Policy for Stopping High-Risk Life Sciences Research have previously relied on the NIH Guidelines to help assess experimental risk of formerly DURC/PEPP and now DGOF. A similar expectation will likely exist for the new NIH Biosafety Policy to set a standard for reviewing research and anticipating risk. Unlike the broad geographic scope of the High-Risk Policy, the Biosafety Policy applies to biomedical research "in laboratory settings." Thus, the IBC will likely need to expand its oversight to cover all life sciences research, including that outside of a lab setting, to meet these conflicting requirements. In addition, determining how to evaluate research that appears permissible under the draft NIH policy but may be prohibited or restricted under the High-Risk Policy begs for the two to be deconflicted.

Specifically, the draft NIH policy and the USG High-Risk Policy both add review bodies, reporting duties, and increased scope over life sciences research, and they reach many of the same projects. Institutions need to know how these policies interact so one project is not reviewed, reported, and audited in parallel by overlapping bodies with different timelines and standards. A single, harmonized reporting pathway would reduce burden without reducing oversight. As part of this effort, NIH should consider the creation of a decision tree to help identify when an agent falls under both the NIH policy and the DGOF/IROC framework, particularly when an experiment substantially increases the agent's dangerous biological properties. The decision tree should clarify principal investigator and IBC responsibilities and provide standardized criteria and examples.

Additionally, under the High-Risk Policy, a principal investigator must attest to having undergone institutional review of their life sciences research at the point of a grant application to determine applicability of that policy. This poses challenges related to the NIH policy that should be addressed, as both policies' requirements are considerations for NIH-sponsored research. For example, the lack of overlap between the IBC and IRE purview presents a problem for assessing biosafety risks and mitigation strategies, if the IBC would have previously led the review process and referred to the IRE. Similarly, if the research is inclusive of agents that now require NIH review and approval before containment can be set, the principal investigator is unlikely to be able to submit the grant in time for such an assessment to conclude, inhibiting research funding. Additionally, the language in these policies encompasses work of different risk/benefit profiles with clear biomedical importance. This is inclusive of research necessary for the study of the mechanisms of action and resistance to treatments and preventative measures against infectious disease. Yet the risk assessment aspects of the policies do not align in terms of how such research may proceed. With strict interpretation, the policies may also inhibit the study of naturally arising variants with changing genetic sequences or protein functions, which are critical for understanding how treatments and prevention strategies can be effectively implemented.

Definitions. Similar to the associations, key operational definitions, such as biohazard, emerging agent, novel agent, zoonotic agent, genetic modification, and toxin, require additional specificity to ensure that they do not unintentionally expand the scope of the policy to encompass routine and low- risk activities. Specifically, we recommend the following additions and clarifications:

- *Animals/ Animal Work (addition)*: Since the proposed policy is focused on human health risks, we recommend a new definition of animals/animal work as follows to clarify what oversight remains for human health studies involving animal models: "Organisms in the Kingdom Animalia, excluding whole arthropods, arthropod eggs, and parasitic worms; includes whole animals and materials derived from animals."
- *Biohazards*: We recommend clarification to ensure consistency in the application of the criterion throughout the policy and to support a clear nexus to human disease. Specifically, as research focused on animals, plants, and arthropods may result in secondary effects on human health, the NIH should clarify when these types of work are covered under the policy. One example would be gene drive experiments that affect arthropod vectors of human disease such as genetic modification of mosquitos to reduce malaria transmission. Additionally, NIH should provide concrete examples of activities that are in scope and out of scope, particularly for animal pathogens, agricultural and plant pathogens, environmental organisms, and prions and other self-aggregating proteins, as these categories sit at the margin of the human-disease criterion, and defined examples will permit institutions to be consistent in how these materials are classified. Finally, the term "parasite" could be interpreted to parasites possibly leading to human disease (e.g., ticks, mosquitos). We suggest instead "protozoan organisms considered parasitic to humans."
- *De Novo Review (added).* We recommend the following definition of De Novo Review to be added to the policy: "An IBC submission of a registration that may be new or have been reviewed and approved previously by an IBC.
- *Emerging Agent or Organism*. We urge clarification of the draft policy's definition of emerging agent or organization to link back to "risk to human health", and it should be supported by NIAID's list of emerging diseases. Specifically, the definition should define how much an organism needs to deviate from known species before it is considered "emerging" or "new" under the policy. Typically, pathogens are considered "emerging" when they increase in incidence, expand geographically, acquire new host ranges, or change epidemiologically.
- *Genetic Modification*: We recommend that NIH clarify whether the policy applies to transient expression systems, engineered phage, and other low-risk work that creates no reasonable human-health hazard. We suggest that genetic modification should be one factor in risk assessment, not an automatic indicator of elevated risk. The definition unintentionally classifies naturally evolving organisms as genetically modified. Additionally, mutations acquired through passaging and exposure to chemicals/radiation should not constitute "genetic modification" as this could occur in nature. The following line should be removed from the definition: "The introduction into cells, organisms, or viruses of stable alterations into the genome by passaging, reassortment, chemical or radiological means." It is unclear if the definition also applies to RG1/BSL-1 experiments, as its inclusion in the category of "biohazard" is inconsistently applied throughout the document.
- *Novel Agent or Organism*: We suggest that "novel agent" or organism should be defined by biological properties and plausible hazards, not simply by whether an organism exists in nature. The NIH definition should distinguish between something that is "novel" vs "genetically modified". For example, if a viral vector is considered "genetically modified" or a "novel agent". If a "novel agent" is defined by a percentage of its genome or protein structure that differs from an organism that exists in nature, NIH also should further expand the examples, such as "chimeras" and "organisms generated by synthetic biology in conjunction with artificial intelligence."
- *Prions and Self-aggregating Proteins*: Not every self-aggregating protein is infectious, transmissible, or capable of causing neurodegenerative disease. Infectious PrP prions, protein-seeding models, and noninfectious aggregation research represent different hazards and should not automatically be treated as of equivalent risk. We suggest that NIH clarify how they will

determine if proteins “cause neurodegenerative disease”. Several proteins are associated with such disease, but it is unclear if they “cause” the disease. NIH should provide examples and criteria to support consistent determination, and it should consider a process for later classification of proteins with currently unknown or incompletely characterized functions.

- *Toxins*: NIH should remove toxins and proteins from the policy since many toxins of risk to humans meet the definition for chemicals of acute toxicity and have existing requirements for handling under OSHA (29 CFR 1910.1450). If retained, we suggest the following revisions: reference the definition of a toxin used by the Federal Select Agent Program and provide examples; eliminate the vague "causes harm in humans" in favor of objective criteria, given that harm depends on dosage; incorporate the LD50 or similar threshold-based criteria to determine whether a substance meets the definition of a biological toxin; provide exclusion criteria consistent with the Federal Select Agent Program, such as toxins in their natural environment; and clarify how uncharacterized proteins from venomous animals should be handled. In drug-discovery research with venomous animals, venoms are extracted (proteins or genetic material) from their venom-producing glands. This means that physiologically “normal” proteins/genes and venom (toxic) proteins/genes will be extracted in the same experiment. This imposes a requirement to conduct purification, fractionation, analytical characterization, and computational identification of all novel compounds before any biological activity assessment can be conducted. A retrospective, non-punitive process should be established for classification of unknown proteins later determined to be “toxins” through experimentation.
- *Zoonotic*: We would redefine the term as follows: “An agent with known transmission from animals to humans documented to cause human disease as observed through clinical case presentation.” NIH should provide examples to support interpretation.

We appreciate NIH’s community engagement efforts and believe that our suggestions will help meet our shared goal of a modernized biosafety oversight framework that is both effective and practicable for institutions. Thank you for this opportunity to comment.

Sincerely,

[redacted]

Rebecca Ryan Caruso
Director, Harvard Committee on Microbiological Safety

Appendix A. Incident Reporting Matrix

A single table — incident category, threshold, responsible body, timeframe, posting requirement — would drive consistency across institutions and is a useful implementation aid NIH could supply as part of an implementation guidance document. The illustrative table below is an example that reflects our reading of the draft. Entries marked "To be specified" identify where the draft is silent or ambiguous; those gaps are the substance of our request.

Incident category	Reporting threshold	Authority	Timeframe	Public posting
Laboratory-acquired infection	Any confirmed or suspected LAI	NIH and IBC	24 hours	To be specified
Loss of containment with potential community risk	Any release with potential for exposure outside the facility	NIH and IBC	24 hours	To be specified
BSL/ABSL-3 or -4 incident	All incidents, regardless of exposure or injury	NIH and IBC	24 hours	To be specified
BSL/ABSL-2 incident with medical treatment	Agent-specific treatment beyond basic first aid — term requires definition	NIH and IBC	24 hours	To be specified
BSL/ABSL-2 exposure, first aid or prophylaxis only	Institutional record; no NIH notification	IBC only	Institutional	To be specified
Animal bite or scratch, no agent exposure	Institutional record; no NIH notification	IBC only	Institutional	To be specified
Spill within containment, no exposure	Institutional record; threshold not addressed in draft	IBC only — to be confirmed	Institutional	To be specified
Shipping or transport deviation	Not addressed in draft	To be specified	To be specified	To be specified
Toxin or protein incident (no RG/BSL assigned)	Not addressed in draft	To be specified	To be specified	To be specified

512. Providence

I am responding: On behalf of an organization

Name:

Name of Organization: Providence

Type of Organization: Healthcare Institution

Role: Healthcare Provider

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

Uploaded File: 2026_10_19_NIH-Biosafety-Policy-Comments.pdf

Description: See attachment.

The Honorable Lyric Jorgenson, PhD
National Institutes of Health
Office of Science Policy
6705 Rockledge Dr., Suite 630
Bethesda, MD 20892

RE: NOT-OD-26-112; Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards

Dear Acting Associate Director Jorgenson:

On behalf of Providence, thank you for the opportunity to provide feedback in response to the National Institutes of Health's request for information on the Draft NIH Biosafety Policy for Research Involving Biohazards published on the NIH website on August 19, 2026.

Providence is a nonprofit health system dedicated to a holistic approach to medicine that employs not only the most advanced treatments to improve outcomes, but also puts compassion and humanity at the heart of every interaction. Together, our 125,000 caregivers (all employees) serve in 51 hospitals, 1,014 clinics and a comprehensive range of health and social services across Alaska, California, Montana, New Mexico, Oregon, Texas and Washington. Guided by our Mission to serve all, we are committed to high-quality, compassionate health care for everyone – regardless of coverage or ability to pay. We help people and communities benefit from the best health care model for the future – today.

Research is vital to Providence's mission of service, compassion and healing. Our research supports that mission with groundbreaking research and evidence-based solutions — keeping more people healthy and making our services more convenient, accessible and affordable for all.

In this letter, we offer comments on the following areas of the proposed rule:

- Research Involving Primary Human Specimens
- Research Involving Established Human Cell Lines
- Research Involving Genetically Modified Cells and Viral Vectors
- IBC Documentation, Public Disclosure, and Protection of Confidential Research Information
- Avoiding Duplicative Oversight and Unnecessary Administrative Delays

Research Involving Primary Human Specimens

Relevant provision: Section IV-2 — Research Requiring IBC Review and Approval Before Initiation

The draft policy identifies research involving primary cells that may be contaminated by adventitious agents as requiring IBC review and approval before initiation.

This provision could encompass an extraordinarily broad range of biomedical research, including routine laboratory studies involving peripheral blood mononuclear cells (PBMCs), lymphocytes, human tumor biopsies, surgical specimens, tumor-infiltrating lymphocytes (TILs), primary tumor cultures, and patient-derived organoids.

These materials are essential to contemporary translational cancer research and are routinely handled under established institutional biosafety practices, including appropriate BSL-2 precautions and universal precautions for potentially infectious human specimens.

Although primary human specimens can contain adventitious infectious agents, the mere possibility of such contamination should not automatically require separate protocol-specific review by the full IBC.

It is important to distinguish between routine handling of potentially infectious human specimens and experimental procedures that intentionally propagate infectious agents, increase exposure risks, or introduce additional biological hazards

Recommendations

Establish Streamlined Institutional Review Mechanisms

NIH should permit institutions to approve routine collection, processing, culture, and analysis of primary human specimens through institution-wide or laboratory-specific biosafety registrations.

Such approvals could cover defined classes of specimens and experimental procedures rather than requiring separate IBC submissions for every scientific research protocol.

Permit Delegated Review of Routine Human Specimen Research

Routine research involving primary human tissues and cells should be eligible for delegated review by an institutional biosafety officer or designated IBC member when established containment procedures are appropriate and no additional biological hazards have been identified.

Reserve Full IBC Review for Activities Involving Increased Biological Risk

Full IBC review should be required when experimental procedures introduce hazards beyond those associated with routine specimen handling, including intentional propagation of infectious agents, modifications increasing pathogenicity or transmissibility, or procedures requiring higher levels of containment.

Clarify the Meaning of “may be Contaminated by Adventitious Agents”

Without additional clarification, this language could encompass virtually all primary human specimens. NIH should specify how institutions should evaluate the likelihood and consequences of contamination and whether routine BSL-2 practices adequately mitigate the associated risks.

Suggested Policy Language

"Research involving routine collection, processing, culture, or analysis of primary human cells and tissues, including blood-derived cells and tumor specimens, may be reviewed and approved through an institutional biosafety registration or delegated review process when the activities are conducted under established containment practices and do not involve intentional propagation of infectious agents or other procedures introducing additional biological hazards.

Separate protocol-specific IBC approval shall not be required for activities covered by an approved institutional or laboratory-specific biosafety registration, provided that the activities remain within the scope of the approved risk assessment."

Research Involving Established Human Cell Lines

Relevant provision: Section IV-3 — Research Eligible for Delegated Review

The proposed policy appropriately recognizes that research involving well-characterized cell lines may be eligible for delegated review.

This is an important distinction because established human cell lines are among the most widely used experimental systems in biomedical research.

Cancer research laboratories routinely employ established tumor cell lines for studies of antigen expression, immune recognition, tumor biology, drug sensitivity, vaccine development, and mechanisms of resistance to immunotherapy.

These studies may involve hundreds of experimental variations using the same cell lines without materially changing the underlying biosafety risks.

Requiring repeated biosafety submissions for routine experimental modifications would add administrative burden without necessarily improving laboratory safety.

Recommendations

Establish a Clear Definition of Well-Characterized Cell Lines

NIH should clarify that well-characterized cell lines include established human and animal cell lines with documented identity, provenance, and appropriate biosafety characterization.

The definition should not depend solely on whether a cell line was obtained from a commercial repository. Research laboratories frequently develop and maintain extensively characterized cell lines that are not commercially distributed.

Permit Laboratory-wide Registration of Established Cell Lines

Institutions should be permitted to approve the use of defined categories or collections of established cell lines under a single laboratory biosafety registration.

Addition of another cell line with an equivalent risk profile should not automatically require a new IBC protocol.

Exempt Routine Experimental Changes from Repeated Review

Changes in culture media, cytokine exposure, drug treatment, antigen expression analysis, immune-cell coculture, and similar procedures should not require additional IBC approval unless they materially alter the biological hazard.

Differentiate Established Cell Lines from Cell Lines with Specific Hazards

Full IBC review should remain available for cell lines containing replication-competent pathogens, producing infectious agents, or presenting other identifiable risks requiring enhanced containment.

Suggested Policy Language

"Research involving well-characterized established cell lines may be conducted under laboratory-specific or institutional biosafety registrations approved through delegated review.

Routine experimental modifications, including changes in culture conditions, noninfectious treatments, and cellular assays, shall not require additional IBC review unless they introduce new biological hazards or materially alter the approved biosafety risk assessment.

Institutions may establish procedures for adding cell lines with equivalent biosafety characteristics to an existing approved registration."

Research Involving Genetically Modified Cells and Viral Vectors

Relevant provisions: Sections IV-2, IV-3, and V-B

The proposed policy requires IBC review for research involving genetically modified cells, viruses, and organisms while allowing delegated review for certain lower-risk experiments, including those involving genetically modified Risk Group 1 agents and replication-incompetent, nonintegrating viral vectors expressing low-risk transgenes.

I support the concept of tiered oversight. However, the proposed distinctions may not adequately reflect the diversity of genetic engineering methods routinely used in contemporary biomedical research.

Genetic modification is now a standard laboratory technique employed to investigate gene function, tumor antigen expression, immune recognition, cellular differentiation, and mechanisms of disease.

Examples include expression of tumor-associated antigens or noncanonical proteins in established cell lines, introduction of T-cell receptors into cultured lymphocytes, CRISPR-mediated gene knockout or modification, transient expression of reporter genes, use of replication-defective lentiviral or retroviral vectors, and genetic modification of tumor cells for studies of immune recognition.

These approaches have markedly different biological risk profiles.

The use of genetic modification alone should not determine whether a protocol requires full IBC review. Instead, the level of oversight should reflect the actual hazards associated with the modified cells, vectors, expressed products, and experimental procedures.

Recommendations

Expand Delegated Review to Additional Categories of Low-risk Genetic Modification

NIH should consider extending delegated review eligibility to well-characterized replication-defective integrating vectors, including selected lentiviral and retroviral vector systems, when the overall risk assessment supports this approach.

Although integration introduces additional considerations, it does not necessarily justify full IBC review for every experiment.

Differentiate Genetic Modifications According to their Biological Consequences

The risk assessment should consider whether a modification increases pathogenicity or transmissibility, produces an infectious or replication-competent agent, alters host range or tissue tropism, introduces a

toxin or other hazardous gene product, or otherwise increases risks to laboratory personnel or the environment.

Routine expression of nonhazardous proteins, reporters, or tumor antigens should generally qualify for streamlined review.

Permit Platform-based Approvals for Commonly Used Vector Systems

Institutions should be able to approve defined vector platforms and associated laboratory procedures through a single biosafety registration.

For example, a laboratory routinely using a characterized replication-defective lentiviral vector platform to express nonhazardous proteins should not require an entirely new IBC protocol for each transgene, provided the new construct does not materially change the biosafety risk assessment.

Establish a Streamlined Amendment Process

Minor changes involving nonhazardous transgenes, reporter constructs, or experimental targets should be eligible for administrative or delegated review.

Full IBC review should be reserved for modifications that materially increase biological risk.

Distinguish Genetically Modified Producer Cells from Final Investigational Products

In cancer vaccine and cell therapy development, genetically modified cells may be used to manufacture products that do not themselves contain viable genetically modified cells or replication-competent vectors.

NIH should clarify that biosafety assessments of manufacturing activities and final products should be based on their respective hazards.

A final nonreplicating, nonintegrating, cell-derived vaccine product should not automatically be assigned the same biosafety risk classification as the genetically modified cells used during its manufacture.

Suggested Policy Language

"Research involving genetically modified cells or viral vectors shall be assigned to an appropriate level of oversight based on the biological characteristics of the modified material, the properties of the introduced genetic elements, the potential for replication or dissemination, and the risks associated with the proposed experimental procedures.

Delegated IBC review may be used for research involving well-characterized replication-defective vector systems and genetic modifications that do not materially increase biological hazards, when supported by a documented institutional risk assessment.

Institutions may approve established genetic modification platforms through laboratory-specific biosafety registrations. Changes in transgenes or experimental constructs that do not materially alter the approved risk assessment may be addressed through streamlined amendment procedures."

IBC Documentation, Public Disclosure, and Protection of Confidential Research Information

Relevant provisions: Delegated IBC Review, IBC Meeting Minutes, and Public Disclosure Requirements

The proposed NIH Biosafety Policy would require actions approved through delegated review to be reported "in full" at the next scheduled Institutional Biosafety Committee meeting and documented in the meeting minutes. The policy also provides for public posting of approved IBC meeting minutes, subject to allowable redactions.

While transparency and institutional accountability are important objectives, these provisions raise significant concerns regarding the disclosure of unpublished scientific research, intellectual property, proprietary research methods, confidential personnel information, and laboratory security-sensitive information.

These concerns are particularly important for translational biomedical research institutions conducting innovative research in cancer immunotherapy, vaccine development, genetic engineering, and investigational therapeutics, frequently in collaboration with biotechnology companies and pharmaceutical partners.

IBC protocols may contain detailed descriptions of experimental approaches, unpublished discoveries, novel constructs, proprietary manufacturing methods, and research strategies that have not yet been patented or publicly disclosed.

Public disclosure of such information could compromise intellectual-property protection, interfere with scientific publication, undermine contractual confidentiality obligations, and discourage academic-industry collaborations.

In addition, IBC records may contain information concerning laboratory locations, biological agent inventories, occupational-health considerations, personnel responsibilities, and security measures that should not be disclosed publicly.

The requirement that delegated approvals be reported "in full" is particularly concerning because it is unclear whether this refers to a complete description of the underlying research protocol or a complete accounting of the IBC's review and approval actions.

NIH should explicitly distinguish between complete internal documentation of biosafety decisions and the information necessary for meaningful public transparency.

Recommendations

Define the Minimum Information Required in Publicly Posted IBC Minutes

NIH should establish clear and consistent standards identifying the information necessary to document IBC oversight and institutional accountability.

Public records should document the committee's actions, including quorum, recusals, risk determinations, approval conditions, and voting outcomes, as applicable, without requiring disclosure of confidential protocol-level scientific information.

Clarify the Meaning of Reporting Delegated Approvals "in Full."

NIH should specify that this requirement refers to a complete accounting of delegated review decisions, including the nature of the activity, applicable risk classification, approval determination, and any conditions of approval.

It should not require public disclosure of complete research protocols, experimental methods, genetic constructs, unpublished findings, or other confidential scientific information.

Establish Explicit and Consistent Redaction Standards

The final policy should authorize appropriate redaction of information involving unpublished scientific discoveries, patentable inventions, intellectual property, trade secrets, proprietary experimental methods, confidential sponsor information, personally identifiable information, occupational-health information, biological agent inventories, sensitive laboratory locations, facility vulnerabilities, and security controls.

NIH should provide clear guidance to promote consistent implementation across institutions and minimize uncertainty regarding permissible redactions.

Establish a Reasonable Period for Public Posting

The requirement for immediate posting of approved IBC minutes could create substantial administrative and compliance burdens.

Institutions require sufficient time to conduct appropriate privacy, intellectual-property, security, legal, and communications review before releasing documents publicly.

NIH should establish a reasonable, defined posting period following approval of meeting minutes rather than requiring immediate publication.

Permit Standardized Public Summaries while Retaining Complete Internal Records

NIH should permit institutions to prepare standardized public summaries of IBC proceedings that provide meaningful information about biosafety oversight without disclosing confidential or security-sensitive information.

Complete, unredacted meeting minutes, protocol submissions, risk assessments, and supporting documentation should be maintained internally and made available to NIH and other authorized oversight authorities as required.

This approach would preserve regulatory accountability while reducing the risks associated with public disclosure.

Suggested Policy Language

"Institutions shall maintain complete internal records of IBC proceedings, delegated reviews, risk assessments, approval determinations, and associated supporting documentation.

Publicly available IBC records may consist of appropriately redacted meeting minutes or standardized summaries that document committee actions, risk classifications, approval decisions, conditions of approval, quorum, recusals, and voting outcomes, as applicable.

Reporting delegated approvals 'in full' shall require a complete accounting of the review actions and determinations, but shall not require public disclosure of complete research protocols or confidential scientific, proprietary, personnel, occupational-health, or security-sensitive information.

NIH shall establish uniform standards for permissible redactions and a reasonable period following approval of IBC minutes for institutions to complete appropriate confidentiality, intellectual-property, privacy, legal, and security reviews before public posting.

Complete, unredacted records shall be retained by the institution and made available to authorized oversight authorities as required."

Avoiding Duplicative Oversight and Unnecessary Administrative Delays

An overarching concern is the potential for duplicative oversight across institutional review systems.

Biomedical research institutions already maintain established processes involving Biosafety Committees, occupational-health programs, Institutional Review Boards, Institutional Animal Care and Use Committees, and other research compliance offices.

For studies involving investigational therapies, additional oversight is provided through FDA requirements and institutional clinical research governance.

Although these systems serve different purposes, unnecessary duplication of administrative review should be avoided.

NIH should explicitly encourage coordinated review and recognition of existing institutional risk assessments.

In addition, NIH should establish clear expectations for timely delegated review and distinguish between modifications that require prospective approval and routine changes that can be documented within an existing approved protocol.

NIH should provide model umbrella registrations, model public summaries, redaction examples, and implementation guidance before the policy becomes effective.

Conclusion and Requested NIH Actions

The proposed NIH Biosafety Policy presents an opportunity to modernize biosafety oversight while improving the efficiency of biomedical research.

Providence supports NIH's objective of strengthening biosafety through a scientifically grounded, risk-based framework. However, achieving that objective requires distinguishing research involving meaningful biological hazards from routine laboratory procedures conducted under well-established containment practices.

We encourage NIH to incorporate the following principles into the final policy:

1. Permit institution-wide or laboratory-specific biosafety registrations for routine studies involving primary human specimens.
2. Expand delegated review eligibility for low-risk research involving human tissues, established cell lines, and well-characterized genetic modifications.
3. Allow platform-based approvals for established cell culture and viral vector systems.
4. Require additional IBC review only when experimental changes materially alter the underlying biosafety risk assessment.
5. Distinguish the risks associated with genetically modified manufacturing systems from those associated with final investigational products.
6. Establish clear standards for public disclosure of IBC proceedings, including minimum reporting requirements, permissible redactions, and reasonable timelines for public posting.
7. Permit standardized public summaries of IBC decisions while requiring institutions to retain complete, unredacted records internally, thereby protecting unpublished scientific discoveries, intellectual property, confidential personnel information, and laboratory security-sensitive information.

8. Promote coordination with existing institutional and federal oversight systems to avoid unnecessary duplication and delays.

NIH has an opportunity to establish a modern framework that directs regulatory attention and institutional resources toward research presenting meaningful biological risks while allowing routine biomedical research to proceed efficiently under established safety practices.

The success of this policy should ultimately be measured not by the number of protocols subjected to review, but by its effectiveness in protecting research personnel, patients, and the public while enabling responsible scientific innovation.

Thank you for the opportunity to provide feedback on the Draft NIH Biosafety Policy for Research Involving Biohazards. We hope you find our input informative. For more information about the views we have expressed, please contact our government affairs team at anne.mitchell@providence.org

Re: Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Dr. Jorgenson:

The International Gene Synthesis Consortium (IGSC) appreciates the opportunity to provide comments in response to the Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards. The IGSC is the industry association for commercial gene synthesis. Our member companies produce a substantial share of the world's synthetic DNA, and since our founding in 2009, we have developed and voluntarily implemented the Harmonized Screening Protocol to screen every order against a curated database of pathogen sequences, verify customer legitimacy, and keep records to support legitimate investigations.

Our comments below are focused on the continued utility of Risk Groups (RGs) as a baseline for risk assessment versus use of Biosafety Levels (BSL), and specifically, how this policy is applied to synthetic biological agents and emerging technologies, especially those that employ artificial intelligence (AI). The IGSC believes that RGs should be retained as a baseline for wild-type work but are not sufficient for engineered or multi-source constructs. The IGSC members have a distinct vantage point on risk groups and the strengths and limitations of this approach. Our companies perform a similar risk characterization to ensure our products are used only for peaceful and productive purposes, including scientific research. We have encountered methodological limitations in this process, and this perspective, which we hope is valuable to your efforts, is shared below.

Summary of Recommendations

1. Retain RGs as the baseline for risk assessment of wild-type agents, but do not extend them as the sole basis for assessing engineered, multi-source, or computationally designed constructs.
2. Support the development of a function-based layer of analysis alongside taxonomic classification, which should include areas where sequence-function understanding is weakest.
3. Coordinate with CDC, NIST, the Bureau of Industry and Security, USDA, and international governments and organizations so that function-based criteria developed for biosafety oversight and for nucleic acid synthesis screening remain aligned.
4. Support the establishment of an "Allow List" of sequences and functional elements determined not to contribute to pathogenicity, so that NIH and IBC review capacity is reserved for higher-risk research.
5. Set a defined NIH response timeline for determinations under Section IV-1, with a default pathway allowing IBC approval to proceed if NIH does not respond within that period.

Section V-C: Requirements and Considerations for Risk Assessment for Synthetic Biological Agents or Emerging Technologies

Our experience is that the existing RGs remain a useful baseline for wild-type work and should be retained in that context, but the RG construct breaks down when it comes to the new and emerging synthetic products. The IGSC appreciates the NIH's recognition of the challenges advances in synthetic biology and related technologies pose for ensuring biosafety. We agree that it is becoming easier to develop engineered organisms that are increasingly complex to classify based on risk. Currently, there is not yet an appropriate substitute for the RG construct for this type of agent. As you further consider this topic, we urge you to consider the existing and growing difficulties associated with understanding what 'endows or enhances pathogenicity' and implications for export control of engineered organisms. In particular, we ask that you recognize that risk assessment challenges are not limited to synthetic biological agents containing genetic sequences from multiple sources. AI protein design tools, while enabling remarkable scientific breakthroughs, are introducing new challenges as our scientific community works to understand the risk associated with novel sequences that do not exist in nature.[1]

One reason for these challenges is that our current risk assessment systems define risk at the organism level. This includes Appendix B of NIH Guidelines for Research Involving Recombinant or

[1] https://www.rand.org/pubs/research_reports/RRA4741-2.html

Synthetic Nucleic Acid Molecules[2], which the Agency says it will draw from as it finalizes its new NIH Biosafety Policy for Research Involving Biohazards. Through our work synthesizing and screening nucleic acid sequences, IGSC members have become acutely aware of the limitations of organism-level risk assessments. Nucleic acid synthesis screening approaches are meant to detect sequences associated with pathogenic agents and generally look for sequences that are a 'best match' to controlled, known bacteria, fungi, or viruses.[3] While this approach remains a useful baseline risk assessment strategy, AI-based protein design tools are increasingly challenging the status quo by their ability to create variants of proteins of concern that could evade detection.[4] The nucleic acid synthesis community has developed patches to address these gaps, because currently, to make a functional toxin, models still need significant amounts of known sequence. However, these capabilities are advancing rapidly, and we believe a new non-taxonomic approach is needed for novel biological components and agents.

We applaud the draft policy for anticipating that eventually investigators and Institutional Biosafety Committees (IBCs) will need to conduct a multi-level analysis focused on 1) the RG of the source organism of sequences, 2) the functions those sequences may encode, and 3) the probability of any synergistic effects of the genetic sequences. The first level is tractable; however, existing risk assessment methods cannot address the second and third levels. As such, it is not appropriate to direct IBCs to resolve such questions through deliberation alone. Instead, assessments should use computational methods to predict molecular properties such as structure, binding targets, and functional annotations that may contribute to concerning properties (which themselves await formal definition).

We believe NIH should further support efforts that enable scientists to predict function, including when pathogenic components are in altered contexts. Collaborative public-private conversations are already underway. Specifically, IGSC has funded the Sequence Biosecurity Risk Consortium (SBRC)[5], a community advancing global engineering standards for identifying and managing biological sequences of concern. The work of this body is important for several reasons:

Strengthening nucleic acid biosecurity screening against generative protein design tools. Science (New York, N.Y.), 390(6768), 82–87. https://doi.org/10.1126/science.adu8578

[5] https://www.sbrc.bio

- The SBRC has created a set of scientific principles to assess sequence risk for international application. This has, in part, contributed to the construction of a "sequence of concern" dataset by the National Institute of Standards and Technology (NIST).[6]
- SBRC is working to further define sequences of concern based on gene- or domain-level function, i.e., when predicted molecular properties indicate a capacity for biological "functions of concern".

It is important that government policy and guidance align, and for these reasons, we urge NIH to work cooperatively with the biosecurity-focused stakeholders, other United States federal agencies, including the CDC, NIST, the Bureau of Industry and Security, the USDA, as well as international bodies to further develop our collective scientific understanding of how to evaluate potential for harm based on functions inferred from an agent's components.

The shift from a taxonomic approach to risk assessment would also be valuable because it allows us to identify components known to have functions associated with endowing or enhancing pathogenicity, as well as components with benign functions. Understanding what does *not* contribute to an agent's pathogenic activity is equally important to ensure that resources devoted to risk assessment are used efficiently. For example, non-pathogenic nucleic acid sequences found in thousands of bacterial species are factored into a Common Mechanism, a free screening tool that has been developed to easily allow companies to adopt biosecurity protocols that prevent the misuse of synthetic nucleic acids.[7] This approach is in alignment with recommendations from the 2023 Department of Health and Human Services Framework Guidance for Providers and Users of Synthetic Nucleic Acids.[8]

As discussed further below in our comments under Section IV-1, the IGSC is concerned about the burden on NIH and researchers from the potential volume of determinations NIH would have to make under its draft policy, which requires both NIH and IBC approval before a study can begin. This includes "research involving emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the BMBL."

[8] https://www.aspr.gov/sites/default/files/centers_documents/SynNA-Guidance-2023.pdf

Characterizing what is benign is what makes screening workable at scale; without it, providers would flag sequences that are both ubiquitous and harmless, wasting valuable time and resources. One solution is to allow the federal government to develop an "Allow List" that identifies components and functional elements that do **not** contribute to pathogenicity. Such a list would let NIH clear routine constructs quickly and reserve case-by-case review for genuinely higher-risk research. We recommend that NIH commit in the final policy to developing an Allow List, in coordination with NIST and the nucleic acid synthesis screening community.

NIH should also consider knowledge gaps and where it could contribute to advancing scientific understanding, in part to improve biosecurity assessments. Understanding which sequences contribute to pathogenesis varies across microbial groups, and that unevenness should shape what is achievable today. Bacterial and viral systems are comparatively well characterized, with toxins, secretion systems, and viral immune antagonists often traceable to discrete, experimentally validated sequence elements. The gaps widen for fungi and protozoa, where sequences more often contribute to complex, context-dependent functions such as immune subversion. Fungal virulence, for instance, frequently depends on host immune status and environmental cues and is mediated by traits also required for ordinary growth, so the boundary between a virulence determinant and a housekeeping function may be more difficult to ascertain. Building upon IGSC's previous efforts[9], a significant part of SBRC's work is to define sequences for which their role in pathogenicity is disputed among experts or poorly understood. This can help to focus future research. Targeted investment in these topics would improve both the underlying science and the risk assessments that depend on it.

Section IV-1: Research That Requires NIH and IBC Approval Before Initiation

As noted above, IGSC also has concerns about the proposal in Section IV-1, which routes research involving "emerging, novel, or zoonotic agents for which the RG classification or a recommendation for minimum containment level is not available in the *Biosafety in Microbiological and Biomedical Laboratories* (BMBL)" manual to NIH for a case-by-case determination before initiation. IBCs would be barred from approving the work until NIH makes the determination. IGSC members are concerned that a rapidly expanding category of agents – those engineered or created by computational design – may meet the criteria for NIH review under this section but have no entry in the BMBL. The demands of the new policy on NIH, coupled with a potentially dramatic increase in this new category of agents, raise concerns that the subsequent workload will lead to significant

[9] Wheeler NE, Bartling C, Carter SR, et al. Progress and Prospects for a Nucleic Acid Screening Test Set. Applied Biosafety. 2024;29(3):133-141. doi:10.1089/apb.2023.0033

bottlenecks that could have the unintended consequence of delaying the start of important research projects at institutions. We recommend that the final policy establish a defined timeline for NIH determinations under this section — for example, 30 calendar days from submission. NIH may also consider an approach that is specifically inclusive – starting with well-known pathogens and expanding over time as data becomes available clarifying the potential for pathogenicity of individual genetic components not traditionally thought of as posing significant risk.

The IGSC appreciates the opportunity to provide input on updates to the Biosafety Policy for Research Involving Biohazards and remains committed to supporting robust biosafety and biosecurity frameworks. If you would like to discuss our comments further, please contact James Diggans at info@genesynthesisconsortium.org.

Sincerely,

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biosafety and Biosecurity, Infectious disease research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The NIH Guidelines were originally developed for a different scientific era, and an updated framework is needed to address emerging technologies and biosafety risks that are not adequately captured by the scope of the existing Guidelines. At the same time, NIH has acknowledged that a successful modernization initiative should remove unnecessary oversight of low-risk research. For these reasons, I support NIH's goal of modernizing biosafety oversight and expanding the current framework beyond research involving recombinant or synthetic nucleic acid molecules. While the draft policy expands oversight substantially, several aspects of the proposed scope and associated definitions lack sufficient clarity to ensure consistent implementation and may inadvertently direct limited biosafety expertise toward activities that present little biosafety concern.

The draft defines research involving biohazards as research involving a known or potential risk to human health and certain categories of biological materials. These include wild-type biological agents that cause human disease; genetically modified cells, viruses, or organisms other than plants; toxins, prions, and other self-aggregating proteins; and cells or organisms other than plants containing those materials. While this represents a significant expansion beyond recombinant or synthetic nucleic acid research, the human-health-centered scope and exclusion of plants create potential gaps in biosafety oversight. Human, animal, plant, and environmental health are not mutually exclusive. Under a One Health framework, hazards affecting animals or plants may also have direct or indirect consequences for human health, food systems, ecosystems, or the emergence of disease. The exclusion of plants and the policy's limited treatment of wild-type agents that cause disease only in animals are difficult to reconcile with the stated goal of modernizing oversight for evolving biological risks.

Although other federal agencies provide regulatory oversight for plant and animal health, the NIH Guidelines have historically provided an important institutional framework for local risk assessment, containment determinations, and committee oversight. NIH should reconsider whether these exclusions create gaps in institutional biosafety oversight or leave institutions without a consistent framework for evaluating research involving animal, plant, or environmental health hazards.

Several definitions used to establish the policy's scope also warrant reconsideration. The draft defines a "biological agent" as bacteria, viruses, fungi, or parasites that cause human disease. However, the term

"biological agent" is not universally synonymous with either "pathogen" or "biohazard." In broader scientific usage, a biological agent may simply refer to a biological organism or material, regardless of whether it causes disease. NIH should define "biohazard" according to the capacity of a biological material to cause harm and then distinguish the categories of agents, toxins, prions, and other materials that may meet that definition.

The definition of "biomedical research" is also problematic. The draft defines biomedical research by reference to whether a research topic falls within the mission of NIH. An agency's mission may appropriately determine what research it supports, but it is not a clear scientific or risk-based basis for defining the scope of a federal biosafety policy. Applicability should be determined by the nature and risk of the research rather than whether a particular topic is considered within NIH's mission.

The definitions of "emerging agent or organism" and "novel agent or organism" also require additional clarification. The draft defines an emerging agent or organism as an agent or organism newly identified in nature. In biosafety and public health practice, however, emergence generally refers to a pathogen whose incidence, geographic distribution, or significance is increasing or becoming newly recognized. It does not typically refer to the discovery of a previously unknown organism. Zika virus is a useful example. The virus was known for decades before it emerged as a significant public health concern. What emerged was its significance as a human pathogen, not the organism itself.

The draft's definition of a novel agent or organism raises a related concern. NIH uses the term to describe an agent or organism that does not exist in nature and has been deliberately designed, potentially using components from multiple natural or synthetic sources. However, the terms "novel agent," "novel organism," and "new organism" do not inherently imply deliberate design, pathogenicity, or hazard. Scientists routinely identify previously unknown organisms in nature, and the overwhelming majority have no known adverse consequences for human, animal, or plant health.

The common issue with both definitions is that they place substantial emphasis on whether an organism is new rather than whether it presents a biosafety concern. An organism may be newly discovered without posing a hazard. An organism may be emerging because its significance as a pathogen has become apparent, even though it has been known for decades. Likewise, a deliberately engineered organism may present little or no biosafety concern. NIH should clarify these definitions to ensure institutions focus on identifying hazards rather than determining whether an organism is merely newly identified, newly designed, or otherwise unusual.

Perhaps the most consequential expansion of scope is the inclusion of genetic modifications induced through chemical or radiological means. I understand and support the apparent intent to capture biologically significant changes that may arise through methods other than modern molecular techniques. The concern is not with that intent, but with the breadth of activities the definition may capture.

As written, the definition could bring broad categories of routine chemical mutagenesis, radiological mutagenesis, random mutagenesis, passaging, or selection experiments within IBC oversight even when they do not create a meaningful biosafety concern. Greater clarity is needed regarding which modifications warrant institutional review and which do not.

This concern extends beyond administrative burden. Biosafety professionals and IBC members have limited time and highly specialized expertise. Requiring review of large numbers of low-risk activities can divert attention from hazards that are consequential but not always readily apparent. NIH should provide implementation guidance, including worked examples that clearly distinguish activities requiring IBC registration or review from those that fall outside the intended scope of the policy.

Finally, while I support the inclusion of toxins within the policy's scope, NIH should establish explicit criteria for determining which toxins and uses are subject to the policy. Such criteria should consider toxicity, quantity, concentration, route of exposure, LD50 values, or other scientifically defensible measures of risk. Without clear criteria, institutions are likely to implement the policy inconsistently. Some may adopt highly conservative interpretations that result in registration and review of relatively low-risk materials, while others may reach different conclusions. As with several other areas of the draft policy, clearer boundaries are needed to help institutions reach similar conclusions regarding what research warrants biosafety oversight.

Overall, I support broadening biosafety oversight beyond recombinant and synthetic nucleic acid technologies. However, the scope should more clearly distinguish biological materials from biohazards, newly discovered organisms from emerging pathogens, and genetic modification from changes that alter biosafety risk. Clearer boundaries are needed to prevent inconsistent interpretation and unnecessary review of low-risk activities.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): Tiered Oversight and Categories of Review

I generally support NIH's concept of a tiered oversight structure that assigns oversight responsibilities among investigators, institutions, IBCs, and NIH based on risk. However, several aspects of the proposed framework warrant reconsideration to ensure that oversight remains focused on activities that present genuine biosafety concerns and that finite biosafety resources and review capacity are focused on activities that present the greatest uncertainty and potential consequence. The areas of greatest concern involve (1) NIH approval requirements for certain containment determinations and (2) the treatment of activities subject to delegated review.

NIH Approval of Containment Determinations for Emerging, Novel, and Zoonotic Agents

The draft policy requires institutions to petition NIH before research involving certain emerging, novel, or zoonotic agents may proceed when a Risk Group classification or recommended containment level is not available. NIH approval is also required before lowering containment for certain agents and activities. This requirement should be reconsidered. The absence of a specific Risk Group classification or recommended containment level in the BMBL does not necessarily indicate that a biological agent presents unusual uncertainty or warrants mandatory federal review. The BMBL cannot reasonably be expected to provide containment recommendations for every biological agent that may become the subject of research, nor should the absence of a specific recommendation automatically prevent an institution from conducting its own risk assessment.

Institutions routinely evaluate biological agents using established risk assessment principles, available scientific literature, agent characteristics, proposed manipulations, available medical countermeasures, and containment guidance provided in the BMBL. These same approaches can be applied when institutions encounter agents that are not specifically addressed in the BMBL. In many cases, sufficient information exists for an IBC to conduct a thorough risk assessment and establish appropriate containment even when a specific Risk Group classification or BMBL containment recommendation has not been established.

Continued use of Risk Groups would further support this process. Risk Groups provide institutions with a familiar and broadly accepted framework for classifying biological hazards based on their characteristics and potential hazards. When an agent is not specifically classified, institutions can evaluate available information regarding pathogenicity, route of transmission, host range, availability of preventive or therapeutic measures, and other relevant factors to determine an appropriate Risk Group classification.

That classification can then serve as the starting point for determining appropriate containment through the BMBL risk assessment process.

For example, if an agent has been documented to cause disease in humans, has reasonably understood transmission characteristics, and possesses characteristics consistent with a Risk Group 3 pathogen, an experienced IBC should generally be able to conduct a thorough risk assessment and establish containment beginning from a BSL-3 baseline without requiring prior NIH approval simply because the agent lacks a specific BMBL listing.

Containment determinations also depend on local considerations that cannot be fully evaluated at the national level. Geographic location, environmental conditions, competent arthropod vectors, occupational health resources, emergency response capabilities, institutional expertise, and facility characteristics all play a role in risk assessment. An arthropod-borne pathogen may present substantially different considerations for an institution located near the Canadian border than for one located on the Gulf Coast. Local IBCs are often best positioned to evaluate these site-specific factors.

This recommendation should not apply universally. NIH review and approval may be appropriate when research involves agents with substantial uncertainty, unusual pathogenic characteristics, significant biosecurity concerns, or the potential for widespread public health consequences. I also support NIH's proposal to require approval before lowering containment for gene drive-modified organisms, as the ecological and environmental consequences of these technologies remain uncertain.

However, NIH review should be reserved for these higher-concern situations rather than required solely because an agent lacks an established Risk Group classification or recommended containment level in the BMBL. For most agents, institutional risk assessment informed by Risk Groups, established biosafety principles, available scientific literature, the BMBL, and local expertise should remain the primary mechanism for determining appropriate containment.

Delegated Review and Removal of Previously Exempt Activities

My greatest concern with the tiered oversight structure involves the delegated review category.

Under the current NIH Guidelines, certain activities are exempt from IBC review because they have been determined to present sufficiently low risk. Under the draft policy, many of these activities appear to have been moved into the delegated review category. If implemented in this manner, activities that previously required no IBC review could require review by IBC delegates or biosafety staff before they may proceed. This would represent a significant increase in institutional review of activities that have historically been considered sufficiently low risk to warrant exemption.

This change has significant implications for institutional biosafety programs. The issue is not simply administrative burden. Rather, it is the allocation of biosafety resources. Biosafety professionals and IBC members have finite time and specialized knowledge. Requiring review of large numbers of low-risk activities inevitably reduces the time available to identify and evaluate projects that present more significant or less obvious biosafety concerns.

This concern is compounded by the requirement that delegated review approvals be reported to the IBC and documented in meeting records. At many institutions, preparation, review, and approval of IBC meeting minutes already represent a substantial investment of staff time and institutional resources. Requiring large numbers of delegated reviews to be processed, reported, and tracked in a manner similar to higher-risk research is unlikely to improve safety, transparency, or risk assessment outcomes.

If an activity is sufficiently low risk to qualify for delegated review, it should not necessarily require the same level of documentation and reporting associated with full committee review. Otherwise, the distinction between delegated review and full committee review becomes substantially diminished.

NIH should consider retaining appropriate exemptions from the current Guidelines or developing clear exclusions for categories of low-risk research under the new policy. Examples will be particularly important for:

- Genetically modified cells, viruses, and organisms.
- Toxins, prions, and self-aggregating proteins.
- Primary cells and tissues that may contain adventitious agents.
- Other activities that historically fell within exemption categories.

Without clear guidance, institutions will struggle to determine which activities require full IBC review, which qualify for delegated review, and which fall outside the scope of the policy altogether. The result will likely be inconsistent implementation and unnecessary expansion of oversight into activities that present little biosafety risk.

Recommendation

Overall, I support a tiered oversight structure that reserves the most intensive review for the highest-risk research. However, the framework should place greater reliance on institutional biosafety expertise for routine containment determinations and should avoid converting large numbers of historically exempt, low-risk activities into delegated-review activities with extensive documentation requirements.

3. Continued utility of Risk Groups: I strongly support continued use of Risk Groups as part of the biosafety framework. In my view, this should not be framed as a choice between Risk Groups and Biosafety Levels because the two serve different functions.

Risk Groups provide a useful starting point for evaluating the inherent hazards associated with a biological agent. Biosafety Levels are containment recommendations that result from a broader risk assessment process. Risk Groups help characterize the agent, while the BMBL risk assessment framework is used to determine the appropriate containment and risk mitigation measures for the specific research being conducted.

The continued utility of Risk Groups becomes particularly important when agents are genetically modified. Genetic modification does not inherently increase or decrease risk, and the continued utilization of Risk Groups provides a critical baseline for evaluating how a modification changes the hazardous characteristics of an agent and determining the appropriate containment level.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: I support NIH's efforts to improve transparency and establish a more consistent approach to incident reporting. However, several aspects of the incident reporting framework, required reporting thresholds, and public reporting templates warrant reconsideration to ensure that the policy strengthens, rather than discourages, institutional reporting cultures.

Reporting Thresholds and IBC Review

The draft policy appears to substantially expand the number of incidents that must be formally reviewed by an IBC. Under the current NIH Guidelines, reporting requirements focus primarily on significant problems, significant violations, significant research-related accidents or illnesses, and exposures involving recombinant or synthetic nucleic acid research. By contrast, the draft policy requires certain lower-risk incidents to be reported to and reviewed by the IBC, including incidents involving covered research with animals housed at BSL-1/ABSL-1 or BSL-2/ABSL-2 and incidents at those containment levels when first aid is administered but agent-specific treatment is not required.

The policy would benefit from greater clarity regarding the relationship between the incident and the biohazard subject to the policy. As written, it is not always clear whether the incident itself must involve the covered agent or activity, or whether any animal-related event or first-aid event occurring during covered research must undergo formal IBC review.

This distinction is important. A minor injury associated with low-risk research may warrant local review, medical follow-up, and corrective action without necessarily requiring formal IBC review and public reporting. Expanding formal reporting requirements to encompass a large number of low-risk incidents may increase administrative activity without a clear safety benefit.

More importantly, it risks diverting limited biosafety resources away from investigations and corrective actions associated with higher-risk events. Biosafety professionals and IBCs are most effective when their time is directed toward identifying root causes, evaluating meaningful exposures, and preventing significant incidents rather than extensively reviewing events that present little biosafety concern.

Reporting of Potential Laboratory-Acquired Infections

The requirement for immediate reporting of confirmed or potential laboratory-acquired infection also warrants clarification. A confirmed laboratory-acquired infection is a clear reporting threshold. A "potential" laboratory-acquired infection is more challenging because institutions are often unable to determine whether an infection has occurred until an investigation, medical evaluation, and diagnostic testing have been completed.

As written, the requirement may force institutions to speculate about an individual's health status during an active investigation. This may create unnecessary privacy concerns while simultaneously generating reports for events that ultimately prove not to involve an infection at all.

NIH should distinguish a documented or reasonably suspected exposure from a suspected laboratory-acquired infection. Initial notification could be based on an exposure meeting defined criteria, while an LAI determination should follow appropriate medical and epidemiological evaluation.

Public Reporting and the Incident Reporting Template

I do not object to public posting of incident reports, provided the reports contain enough information to explain what occurred, how the institution responded, and what corrective actions were taken without identifying individual researchers.

However, the required incident reporting template should be revised to better protect individual researchers while still preserving transparency. The draft incident reporting template requires inclusion of the principal investigator's name and specifically states that incident reports should not include personally identifiable information other than the PI's name. It further states that names of investigators and information regarding their research may not be redacted solely because they are publicly available elsewhere.

Including the PI's name in publicly posted reports serves little biosafety purpose. The public can understand the nature of the incident, institutional response, corrective actions, and lessons learned without identifying the individual investigator.

This concern is particularly important at institutions conducting animal research, where researchers may already face public scrutiny, harassment, or threats related to their work. Requiring public identification of investigators in incident reports could further discourage reporting and create a perception that the reporting process is punitive rather than corrective.

Institutions with strong reporting cultures often encourage researchers to report even very minor incidents, near misses, and procedural deviations. That culture is critical to effective biosafety oversight. Policies that increase public identification of investigators may unintentionally discourage reporting of

exactly the types of events that provide opportunities for learning and prevention.
NIH should permit publicly posted reports to omit names and other details that would directly or indirectly identify the PI, research personnel, or affected individuals, while retaining the information necessary to understand the incident and institutional response.
Meeting Minutes and Transparency
I support the goal of making institutional biosafety activities more transparent. However, transparency should focus on meaningful biosafety oversight rather than creating reporting requirements that consume substantial institutional resources while providing limited public benefit.
This concern is particularly relevant to both incident review and delegated review activities. If large numbers of low-risk incidents and low-risk protocols are required to be documented in publicly posted meeting minutes at a level of detail comparable to higher-risk activities, institutions will spend increasing amounts of time preparing, reviewing, and approving minutes rather than conducting risk assessments and implementing biosafety improvements.
NIH should consider whether all delegated reviews and lower-risk incident reviews need to be documented in the same manner as full committee deliberations. Meeting minutes should provide transparency regarding the committee's activities, but they should not be structured in a way that effectively eliminates the distinction between delegated review and full committee review.
For delegated approvals and lower-risk incident reviews, the template should permit concise aggregate or summary reporting rather than requiring protocol-level detail comparable to full committee review.
Recommendation
NIH should establish a clearer distinction between incidents that require immediate NIH notification, incidents that require formal IBC review, and incidents that may be managed through institutional biosafety and occupational health processes. The policy should encourage reporting, learning, and corrective action without creating disincentives for investigators to report minor events.
Specifically, NIH should:
• Clarify which lower-risk incidents actually require formal IBC review.
• Refine the reporting threshold for potential laboratory-acquired infections.
• Remove PI names and other identifying information from publicly posted incident reports.
• Ensure that incident reporting templates and meeting minutes focus on the event, institutional response, corrective actions, and lessons learned rather than identifying individual researchers.
• Maintain a reporting structure that encourages robust reporting and continuous improvement rather than one that may discourage reporting of low-risk incidents.
A successful incident reporting system should increase institutional learning and transparency while preserving the reporting culture on which effective biosafety programs depend.

6. Other feedback relevant to this resource: NIH has indicated that it plans to develop implementation resources to support the new policy. While guidance on scope, risk assessment, oversight categories, and incident reporting will be essential, successful implementation will also depend on the institutional authority, qualifications, expertise, and infrastructure necessary to support the expanded responsibilities assigned to IBCs and BSOs.

Implementation Guidance and Worked Examples
The expansion of the policy beyond recombinant and synthetic nucleic acid research will require clear guidance to support consistent implementation. NIH should provide worked examples showing what research is subject to the policy and what research remains outside its scope. Examples are particularly

needed for:
• Genetically modified cells, viruses, and organisms.
• Chemical and radiological mutagenesis.
• Serial passage and selection experiments.
• Emerging and novel agents or organisms.
• Toxins, prions, and self-aggregating proteins.
• Primary cells, tissues, and specimens that may contain adventitious agents.
• Animal studies involving transgenic organisms.
Institutions also need examples distinguishing activities that require full IBC review, delegated review, or no review. This is especially important because activities that were previously exempt from IBC review under the NIH Guidelines appear to fall within delegated review under the proposed framework. Without clear boundaries, institutions will interpret the categories differently and may unnecessarily direct biosafety expertise toward low-risk activities.
Additional guidance should explain how Risk Groups and the BMBL risk assessment framework are intended to work together. NIH should also provide examples showing how institutions should evaluate agents that do not have an established Risk Group classification or a recommended containment level in the BMBL, including when institutional review is sufficient and when NIH consultation or approval is required.
Incident reporting guidance should similarly distinguish among:
• Incidents requiring immediate NIH notification.
• Incidents requiring formal IBC review.
• Incidents that may be addressed through institutional biosafety, occupational health, or laboratory safety processes.
• Near misses and other events suitable for voluntary reporting and institutional learning.
Authority of the IBC and BSO
The draft policy substantially expands the responsibilities of both the IBC and the BSO. Institutions are expected to oversee broader categories of research, perform additional risk assessments, review more incidents, and assume new transparency and reporting responsibilities. However, the draft provides little guidance regarding the authority needed to carry out those responsibilities effectively.
NIH should clarify circumstances in which a BSO may independently intervene to address a significant biosafety concern pending review by the institution or IBC. Guidance should address the BSO's authority to temporarily suspend an activity, restrict an operation, or require immediate corrective action when conditions present a significant risk to personnel, the public, or the environment. This should not be framed as the BSO acting on behalf of the IBC, but as an institutionally designated official exercising defined authority when timely action is necessary.
NIH should also establish clearer expectations for the institutional standing of the BSO, particularly at institutions conducting BSL-3, BSL-4, or gene drive-modified organism research. In these programs, the BSO is not simply an administrative coordinator.
The position serves a critical institutional oversight function and should be afforded authority and independence commensurate with the risks being managed. NIH has already recognized this principle in other oversight frameworks through the role of the attending veterinarian, who is afforded defined authority and institutional standing commensurate with responsibility for animal welfare. A similar approach should be considered for BSOs responsible for overseeing higher-risk biosafety programs.
Qualifications and Competencies

For institutions conducting higher-risk research, NIH should establish expectations for the qualifications and competencies of individuals serving as BSOs. These expectations should recognize the value of advanced scientific education, laboratory research experience, biosafety expertise, professional credentials, continuing education, and demonstrated competency in biosafety risk assessment.

These requirements should be proportional to the risks of the institutional research program. Smaller institutions conducting routine, lower-risk research should not necessarily be subject to the same expectations as institutions operating high-containment laboratories or overseeing gene drive-modified organisms. However, institutions conducting higher-risk research should be expected to appoint BSOs whose training, experience, and authority are commensurate with those responsibilities.

If NIH establishes more formal expectations for BSO qualifications, authority, or institutional structure, implementation should be phased. Institutions will need time to secure resources, recruit qualified personnel, and establish appropriate organizational structures. The existing biosafety workforce may not be sufficient to support immediate nationwide implementation of these expectations.

Conclusion

I support the original intent of NIH's initiative to modernize and strengthen biosafety oversight, but I do not believe the current draft fully achieves that goal. It expands the responsibilities of institutions, IBCs, and BSOs without consistently providing the authority, qualifications, guidance, or institutional infrastructure needed to carry out those responsibilities effectively.

Many of the concerns raised by biosafety professionals are not objections to stronger oversight. They are recommendations for how NIH can achieve stronger oversight more effectively. If NIH seriously considers these recommendations and those offered by others in the biosafety community, the policy could better accomplish its original purpose.

If NIH truly intends to strengthen and promote biosafety, it should be more purposeful in doing so. That means defining not only what institutions must do, but also the authority, professional expertise, resources, and implementation time they will need to do it well.

Uploaded File: Recommendations-to-the-National-Institutes-of-Health-Office-of-Science-Policy.pdf

Recommendations to the National Institutes of Health Office of Science Policy

We support the National Institutes of Health (NIH) goal of protecting human health and the environment through effective oversight of research involving biohazards. We ask the Office of Science Policy (OSP) to clarify coverage, establish accountable institutional authority and minimum program support, and align review and reporting with biological risk. These comments consolidate the community's detailed comments and priority requests and follow the draft policy's section order.
The recommendations below concern the Draft NIH Biosafety Policy for Research Involving Biohazards released August 19, 2026, in Notice NOT-OD-26-112. They are proposed revisions, not statements of current requirements. Each topic explains the relevant draft provision before presenting the requested change.

1. Purpose and program identity

Policy reference Section I
The draft describes safe, responsible, and secure research, but its title emphasizes biosafety. Institutional leadership needs a clear statement of the program it must establish and support.
Requests for consideration. Use a consistent title and define whether the required program encompasses both biosafety and biosecurity. State the obligations for each and whether both must be supported to satisfy the policy. Describe the program's full portfolio, including research safety, compliance, responsible conduct and ethical considerations, training, committee review and approval, and security where applicable. A program should not be understood solely as laboratory safety or committee administration.

2. Scope definitions and implementation

Policy reference Section II

Coverage and decision rules

The draft uses broad scope terms and extends obligations beyond directly NIH-funded work. Institutions need consistent rules for deciding which activities and sites are covered.
Requests for consideration. Provide an applicability table and consistent definitions for screening, Assurances, review documents, and reporting forms. Explain how known or potential risk to human health is established, including credible exposure pathways

and the distinction between plausible risk and remote theoretical risk. Clarify biomedical and laboratory research, and work conducted at or sponsored by an institution, including affiliates, leased space, off-site collaborations, teaching, diagnostic, agricultural, and veterinary activities, without treating every biological activity as covered research.

Requests for consideration. Identify activities requiring no submission or review, documentation only, or prior approval. Explain treatment of exclusions and formerly exempt activities. Clarify whether another federal agency's oversight substitutes for any NIH or Institutional Biosafety Committee (IBC) requirement or supplements it, and identify the documentation needed. Provide coverage examples for plant pathogens, routine cell lines, transgenic rodents, and validated inactivated specimens, with evidence supporting each decision.

Implementation period

The proposed effective date would require institutions to identify newly covered work, expand review capacity, train personnel, and update systems while maintaining ongoing research.

Requests for consideration. Allow at least 12 months for full implementation after final guidance and required templates are available. Establish staged milestones for inventory, staffing, training, systems, Biosafety Assurance approval, and conversion of existing submissions. Where appropriate, permit conversion at a significant amendment or scheduled renewal, with safeguards and priority for higher-risk work. Preserve staggered renewal cycles to avoid unnecessary backlogs.

3. Institutional accountability and Biosafety Assurances

Policy reference Section III A

Accountability and minimum program support

The draft requires institutional compliance, training, and program documentation. These obligations need an accountable senior official and explicit minimum resources.

Requests for consideration. Assign overall accountability to the Chief Executive Officer (CEO) or a specifically authorized senior designee. Define the institutional authority needed to direct the program, secure resources, and implement IBC decisions. Require sufficient staffing, office space, administrative systems, records support, communications, training, and occupational health support, proportionate to the volume, complexity, and risk of covered activities.

Requests for consideration. Define minimum support for an IBC office, including professional and administrative capacity for the number of committees or subcommittees and their workload. Explain whether support should be comparable in

function to that provided to Institutional Review Boards (IRBs) and Institutional Animal Care and Use Committees (IACUCs). Clarify whether separate program and IBC office leadership is required or whether combined roles are acceptable. State when director, associate director, or other professional staffing is necessary, using functional criteria rather than leaving the minimum undefined.

Requests for consideration. Permit qualified shared personnel and contractors when expertise, authority, availability, reporting lines, and accountability are documented. Require written responsibility or reliance agreements for collaborations, core facilities, vivaria, clinical sites, and externally administered IBCs. Assign review ownership, site evaluations, training, incident response, NIH reporting, and verification of corrective actions. Permit shared evaluations and records while preserving each oversight body's authority.

Assurance submission approval and renewal

A Biosafety Assurance is the institution's documentation of compliance submitted for NIH approval. A predictable process is essential to prevent inconsistent submissions and interruptions during timely renewal.

Requests for consideration. Publish a standardized template distinguishing required, conditional, and optional fields. Include institutional identity and sites; covered activities; authority and reporting lines; IBC establishment and procedures; responsible contacts; compliance and incident procedures; shared arrangements; certifications; signatures; and supporting documents. Keep substantive obligations in the policy rather than adding them through templates.

Requests for consideration. Specify define required institutional signatures, the submission system, and completeness criteria. Identify information that must be public and information that may be provided directly to NIH when public posting is inappropriate or unavailable.

Requests for consideration. Publish OSP review criteria and response targets for receipt, completeness review, consolidated revision requests, and approval, with a contact and escalation process for delays. Approval notices should state scope, effective and expiration dates, conditions, and how the approval term is determined. Set renewal deadlines, advance reminders, and update requirements. Provide written continuity of an existing Assurance during review of a complete, timely renewal, subject to continued compliance and defined limits. Address initial approval separately, and specify when recipients, subrecipients, collaborators, and sites need separate Assurances or may use documented reliance.

Public disclosure and record retention

The draft links Assurances to public program records and requires public minutes and incident reports. Institutions need consistent boundaries between internal records, NIH submissions, and public disclosure.

Requests for consideration. Consolidate disclosure rules and establish allowable redactions for personal, medical, proprietary, and security information. Specify whether posting all incident reports includes minor events and voluntary near misses; consider significant-event summaries and aggregate lower-risk reporting where appropriate. Clarify deadlines when NIH has not issued its final response. Explain retention and public-posting requirements for non-NIH-funded work, records linked to multiple awards, and records subject to longer retention.

4. IBC establishment functions and operations

Policy reference Section III B

Formal establishment and independent authority

The draft requires an IBC but should explicitly define appointment authority, institutional support, delegation, and independent decision-making.

Requests for consideration. Add an establishing-an-IBC subsection with the following proposed language.

The institution shall formally establish an IBC through a written charter or equivalent document. The CEO, or a senior official acting under a specific written delegation from the CEO, shall appoint the Chair and members. The IBC shall have the collective expertise required by this policy. Its charter shall define its charge, authority, appointments, and reporting relationships. Additional institutional duties shall be supported by appropriate expertise and resources.

As an agent of the institution, the IBC shall exercise its assigned oversight authority using independent biosafety judgment, free from inappropriate influence or interference. The institution shall designate an Institutional Official with authority to support the IBC and ensure implementation of its decisions. Institutional officials may impose additional restrictions but shall not override decisions to withhold, suspend, or withdraw approval or authorize covered work without required IBC approval. Members shall be able to raise concerns without retaliation.

Core functions and administrative support

Requests for consideration. Separate substantive oversight functions from committee procedures and administrative tasks. Specify that the IBC shall review the biosafety program, including practices, training, emergency preparedness, and continued compliance; conduct or direct periodic risk-based evaluations of facilities, equipment,

and containment; and report findings, deficiencies, and reasonable corrective plans and schedules to the Institutional Official or designee.
Requests for consideration. Authorize the IBC to review concerns, incidents, unsafe conditions, and noncompliance; require corrective measures and oversee resolution; and recommend improvements to facilities, training, and resources. State that the IBC may approve, require modifications to secure approval, or withhold approval of covered activities and significant changes before implementation. Authorize suspension or withdrawal of approval and cessation of unsafe work under written procedures, with prompt notice to the Institutional Official and defined conditions for resumption.
Requests for consideration. Define evaluation intervals in written institutional procedures proportionate to risk. Permit qualified staff evaluations while retaining IBC responsibility for oversight determinations. Identify immediate stop-work authority and subsequent IBC review. The IBC should approve its minutes and substantive determinations; staff should prepare, retain, redact, and post records, communicate decisions, track deadlines, and prepare authorized submissions. Qualified response teams should be able to investigate and take immediate protective action without waiting for a committee meeting.

Committee procedures and conflicts of interest

The draft mixes meeting rules with functions and allows recused members to count toward voting quorum. A project decision needs sufficient eligible reviewers.
Requests for consideration. Create committee operations subsection specifying quorum, voting thresholds, permitted meeting formats, unaffiliated member participation, required expertise, and conflict disclosure and recusal procedures. Require a quorum of members eligible to deliberate and vote on the affected submission. Explain how to proceed when recusals prevent quorum, and when conflicted members can be present to provide only requested information.

Incident thresholds investigations and reporting

The draft's significant-risk reporting threshold sits alongside broad compliance-violation and equipment-failure categories. Institutions need clear distinctions between NIH notification, internal IBC oversight, and minor events managed under institutional procedures.
Requests for consideration. Provide a reporting decision table. Define confirmed exposure, potential laboratory-acquired infection (LAI), containment loss, minor spill, and near miss. Identify violations reportable regardless of risk and those eligible for internal correction. Explain whether any incident at higher containment includes events without a credible biological exposure or release pathway and distinguish equipment malfunctions with maintained backup containment from compromised containment.

Requests for consideration. Clarify how precautionary medical evaluation, prophylaxis, adventitious agents, and mixed or uncertain exposures affect reportability. Specify initial report recipients, whose awareness starts the 24-hour notification clock, minimum initial information, and treatment of uncertainty. Define the start of the 30-day reporting period and permit an interim report when investigation remains incomplete.
Requests for consideration. Allow coordinated investigations by qualified biosafety, occupational health, clinical, veterinary, and other teams. Specify escalation to the IBC based on risk, recurrence, or unresolved concerns while preserving each body's reporting duties. Provide paired examples of a contained and disinfected spill without exposure versus credible exposure or release; maintained backup containment versus containment failure; and an administrative lapse versus unauthorized work with materially different risks. Identify the facts that change the reporting pathway.

Experienced program leadership and the Biological Safety Officer

The draft requires a Biological Safety Officer (BSO) for certain research and assigns BSO duties to another official when no BSO is designated. Assigning duties alone does not ensure qualified leadership for the expanded program.
Requests for consideration. Require every covered institution to designate an experienced, qualified program lead with demonstrated biosafety expertise and authority proportionate to the research portfolio. Define minimum qualifications, institutional access, reporting relationships, resources, and authority to oversee implementation and escalate unresolved risks. If another official performs BSO duties, require equivalent qualifications for those duties.
Requests for consideration. Clarify the relationship among the program lead, BSO, IBC compliance office director, IBC Chair, and Institutional Official. State whether roles may be combined, how independence is protected, and whether the BSO's IBC role is limited to voting membership or includes program administration. Define functional empowerment comparable to other institutional oversight leaders, including animal welfare directors or institutional veterinarians, and whether a senior administrative appointment is needed. A particular title, such as assistant or associate vice provost or vice president, should not substitute for clearly mandated authority and experience.

5. Investigator responsibilities and voluntary reporting

Policy reference Section III C
The draft assigns investigators safe-research duties that intersect with institutionally managed facilities and services. Its voluntary incident-learning pathway also intersects mandatory reporting and disclosure.
Requests for consideration. Clarify how the Principal Investigator (PI) responsibility for safe research interfaces with institutional responsibility for facility maintenance,

engineering systems, and occupational health services. Responsibility should follow the authority and resources needed to perform the function.

Requests for consideration. Explain how confidential voluntary reporting to the National Biosafety Data and Safety Analysis Center (NBDSAC) interacts with mandatory NIH reporting and public posting. Clearly identify the limits of confidentiality and the voluntary learning pathway so institutions can participate without uncertainty about disclosure obligations.

6. NIH implementation responsibilities and coordination

Policy reference Section III D

The draft assigns NIH interpretation, approval, incident-response, and implementation functions. Institutions need timely, consistent decisions and coordination with related oversight systems.

Requests for consideration. Publish submission checklists, completeness criteria, response targets, and escalation routes for NIH determinations and incident responses, consistent with the Assurance process described above. Publish a crosswalk with the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules, federal high-risk research requirements, dangerous gain-of-function and potentially dangerous gain-of-function oversight and Select Agent requirements. Identify review ownership, shared information, and effective dates to reduce duplication.

7. NIH review and containment determinations

Policy reference Section IV 1 with related petition provisions in Section III B

The draft reserves certain containment decisions to NIH. Institutions need practical referral criteria that distinguish required federal authorization from local risk assessment.

Requests for consideration. Consolidate overlapping petition provisions. Define when emerging, novel, zoonotic, or unlisted agents require NIH review, with an explicit decision rule when reference information is absent. Explain when published NIH determinations may be reused, where they will be published, and which changes require a new request. Identify limits on local containment decisions and approvals needed before work begins. Clarify interaction with other federal oversight without assuming one approval replaces all others.

8. IBC review pathways and clinical oversight

Policy reference Sections IV 2 and IV 3 with clinical oversight provisions in Section III B

Category boundaries and continuing review

Broad prior-approval categories overlap with lower-risk categories eligible for delegated review. The distinction among committee review, designated member review, administrative processing, and excluded activities needs to be explicit.
Requests for consideration. Provide a review-pathway table and resolve category precedence. Define minor amendments, well-characterized cell lines, low-risk transgenes, potentially contaminated primary cells, and higher-risk manipulations. State whether Section IV 2 requires a convened committee and make delegation under Section IV 3 optional. Clarify eligibility of initial submissions and minor amendments, including amendments to work originally reviewed under Section IV 2. Distinguish administrative changes from changes requiring reassessment and explain the three-year de novo review process and risk-based continuing review between renewals.
Requests for consideration. Provide decisions for routine transfection, established edited cell lines, and personnel or room changes. Assess containment implications before treating a room change as administrative.

Proposed designated member review procedure

Eligible initial submissions and minor amendments may undergo designated member review at IBC's discretion. All members shall receive notice of pending review, access to materials, and a reasonable period specified in written procedures to request full committee review. Any member may request full committee review before approval; a request after approval shall trigger reconsideration under institutional procedures.
If no member requests full committee review during that period, the biosafety administrator, Chair, or institutional designee may assign qualified, unconflicted IBC member reviewers under an IBC-approved procedure. Reviewers may approve, require modifications to secure approval, or refer to the submission to the full committee. Multiple reviewers must agree; unresolved differences shall go to the full committee. Research or an amendment requiring approval shall not begin until approval is granted. Designated member approvals shall be communicated to the IBC when granted and reported in full at its next scheduled meeting for inclusion in the minutes.

Clinical activities and oversight endpoints

Clinical review provisions address administration risks and permit an oversight endpoint at final dosing. Biological risks may continue beyond dosing, and product categories need clearer boundaries.
Requests for consideration. Oversight endpoints should be based on continuing biological risk, including shedding after final dosing. Distinguish manufactured cell products from direct vector administration. Explain what qualifies as higher-risk manipulation, including aerosolization and bladder infusion examples. Define site responsibilities in multicenter studies. Clarify residual institutional biosafety duties for

excluded single-patient expanded access without implying that the exclusion creates an IBC approval requirement.

9. Risk assessment and specialized materials

Policy reference Sections V A through V E

The draft requires risk assessment and mitigation, but institutions need practical methods for assessing modified, nonviable, and unfamiliar materials and documenting acceptable residual risk. Risk Group (RG) describes agent characteristics; Biosafety Level (BSL) and Animal Biosafety Level (ABSL) describe containment - these classifications should not be treated as interchangeable.

Requests for consideration. Explain how controlling policy requirements and reference guidance interact and how differences are resolved. Allow qualified staff to support assessments while investigators retain their responsibilities and the IBC independently evaluates conclusions. Provide a concise format documenting likelihood, severity, exposure pathways, uncertainty, controls, residual risk, and decision authority.

Requests for consideration. Publish examples for attenuated and opportunistic agents; toxin potency, dose, and form; prions and self-aggregating proteins; and validated inactivation. Address short, unknown, proprietary, and artificial intelligence (AI) designed sequences. Explain how encoded function, expected phenotype, and uncertainty affect containment. Distinguish functional gene drives from components, split systems, and intermediates. Clarify influenza strain, segment, and pseudotype combinations and when previous containment determinations remain applicable.

516. University of North Carolina at Chapel Hill

I am responding: On behalf of an organization

Name: Chris Broberg

Name of Organization: University of North Carolina at Chapel Hill

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biomedical, infectious diseases, cancer, pharmaceutical development, public health

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposal addresses circumstances in which risks may arise outside the current rsNA-centered framework in that substantial biological risks can arise from wild-type agents, primary specimens, prions, toxins, and other materials that do not necessarily involve recombinant or synthetic nucleic acids. However, the draft's scope raises several questions.

• Primary human materials and clinical specimens. The draft specifically includes primary cells that may contain adventitious agents. NIH should clarify when routine use of human tissues, blood, diagnostic specimens, and established clinical specimen workflows constitutes research requiring IBC approval, as opposed to activities already managed through institutional exposure-control, laboratory safety, and clinical policies.

• Well-characterized cell lines and biological reagents. The draft includes well-characterized cell lines in the delegated-review category, yet the definition of covered biohazards and the conditions for determining that a line presents negligible risk need to be explicit. Otherwise, work that has historically required little or no separate committee attention may generate additional registrations.

• Toxins and self-aggregating proteins. The draft defines toxins as proteins or peptides produced by living organisms that cause harm in humans. NIH should clarify the intended treatment of nonprotein toxins, synthetic or chemically modified biological products, nonpathogenic model systems involving disease-associated proteins, and proteins whose risks are not equivalent to those of infectious agents.

• Research boundaries. Clarify how the policy applies to diagnostic testing, quality-control work, clinical laboratory operations, teaching, core facilities, repository activities, and incidental handling of specimens when those activities intersect with biomedical research.

We support expanding biosafety oversight to encompass biological hazards that may not involve recombinant or synthetic nucleic acids. We recommend that NIH provide more precise scope definitions, including examples of activities that require registration or review and activities that may be managed under existing institutional programs without a separate IBC submission. The policy should clearly distinguish research involving a meaningful biological hazard from routine clinical, diagnostic, educational, and laboratory activities that do not present a comparable risk. NIH should also clarify how

the policy applies to non-NIH-funded work across institutions with funding from non-Federal sources. While we support a broader risk-based biosafety framework, the proposed scope could substantially increase the volume of protocols requiring registration, administrative review, and committee oversight. Without clearer boundaries, institutions may default to submitting a wide range of low-risk activities for IBC review to ensure compliance. This could divert limited committee and biosafety professional resources away from higher-risk research activities and ultimately reduce the effectiveness of oversight. NIH should ensure that expanded scope is accompanied by clear exclusions, exemptions, and risk-based screening mechanisms that prevent unnecessary administrative burden while maintaining appropriate biosafety protections.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): We support risk-tiered oversight and delegation of appropriate reviews. To achieve the stated goal of reducing administrative burden, NIH should define the criteria that distinguish full IBC review from delegated review and administrative screening. Institutions should be permitted to establish documented, risk-based procedures for routine activities and amendments, subject to IBC oversight and escalation when risk changes. The framework should focus committee attention on activities with meaningful biosafety uncertainty or consequence rather than on the number of registrations generated.
We recommend the NIH:
• Establish explicit criteria for full committee review, delegated review, administrative screening, and exemption from separate IBC review.
• Permit documented, institutionally approved risk-triage procedures rather than requiring a separate registration for every covered material or activity.
• Allow the IBC to approve a defined research scope with clearly specified boundaries, so that scientifically equivalent amendments do not repeatedly trigger full review.
• Permit institutional biosafety professionals to perform routine oversight and verify compliance under written IBC-delegated authority.
• Clarify whether and how protocols can be reviewed jointly, or cross-referenced, when they involve the same or equivalent agents, facilities, personnel, and containment controls.
• Explicitly recognize that existing institutional programs, including occupational health, laboratory safety, bloodborne pathogen, clinical laboratory, and animal care programs, may serve as equivalent oversight mechanisms for certain low-risk activities.

3. Continued utility of Risk Groups: Risk Groups and Biosafety Levels should remain complementary components of the framework. RG classifications provide a useful baseline for intrinsic agent risk, while BSL/ABSL determinations must reflect the specific procedures, modifications, exposure routes, biological systems, and containment capabilities involved. NIH should provide consistent decision criteria and timely determinations for novel or uncertain agents, while preserving institutional authority to impose more protective controls based on local risk assessments.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): We support effective compliance mechanisms that reinforce institutional accountability and encourage timely reporting. We recommend a graduated corrective-action framework that distinguishes administrative deficiencies, promptly corrected deviations, and serious or repeated biosafety violations. NIH should harmonize reporting requirements with other applicable federal programs, define reportability thresholds clearly, and establish standardized protections for sensitive information. A de-identified, nonpunitive system for learning from

near-misses would strengthen biosafety culture and improve the quality of incident data.
Compliance requirements should be calibrated to risk and should avoid creating reporting expectations that disproportionately burden institutions while providing limited biosafety benefit. Excessive reporting of low-risk administrative deviations could obscure identification of significant biosafety concerns and discourage timely reporting of minor events and near-misses. Providing processes for variances from NIH policy including providing institutions with a notice of non-compliance, an opportunity to respond to such a notice, and a challenge or appeal process would also drive reporting compliance.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Transparency should make oversight understandable and accountable without making public records a source of additional safety or security risk. The current NIH framework already includes public-facing IBC minutes with content requirements recently updated. Public release of incident reports should serve to inform the public and institutional personnel such that policies and procedures can be improved without risking the release of sensitive personal or research data. Minor and near-miss incidents should generally remain subject to internal institutional review rather than public reporting requirements, thereby encouraging timely reporting and corrective action. Annual aggregate data of reported near misses, or summaries of events, could be reported to allow for learning form made mistakes.
Incident reporting requirements should balance transparency with administrative feasibility. Public reporting requirements that are overly broad, duplicative, or insufficiently risk-based may require significant institutional resources while providing limited additional value for biosafety improvement. Reporting structures should focus on incidents with meaningful biosafety or public health significance, while allowing institutions flexibility to manage minor events and near-misses through internal corrective-action processes.

To facilitate the release of information, we recommend the NIH establishes:
• A uniform definition of the information that must appear in public minutes.
• Explicit rules for redacting protected health information, identifiable employee information, confidential research details, and sensitive security information.
• A standard procedure for institutional review before publication, including who makes the redaction determination and how disagreements are resolved.
• Clear expectations for the treatment of incidents involving multiple protocols, departments, or facilities.
• A practical publication schedule that accounts for incident investigation, institutional review, and required agency coordination.
• Standardized templates that do not inadvertently compel institutions to disclose more sensitive information than necessary.

6. Other feedback relevant to this resource: Successful implementation will require more than publication of a final policy. NIH should provide a detailed policy implementation guide, standardized templates, model procedures, examples for complex research settings, and authoritative guidance for recurring questions. We recommend a phased implementation approach, explicit transition rules for existing approvals, and an evaluation period that allows institutions and NIH to identify unintended burdens or gaps before additional requirements are imposed.
The draft anticipates implementation six months after publication of the final policy. It also contemplates additional guidance on IBC functions, RG classifications, containment, occupational health, and selected

high-risk research categories.
Six months is likely insufficient to inventory newly covered activities, revise policies and electronic systems, train investigators and committee members, and update public-facing reporting procedures. With an appreciation for the extensive nature of the changes proposed, a 12-to-24-month period would allow for a well planned and executed implementation.
NIH should conduct and publish an assessment of the anticipated administrative impact of the revised Guidelines, including estimated increases in protocol registrations, review volume, incident reporting, training requirements, and staffing needs. Many IBCs operate with limited administrative support and biosafety staffing. Expansion of review responsibilities without corresponding flexibility, delegation authority, or additional resources may create challenges for timely protocol review and effective oversight.
Institutions will likely need substantial modifications to electronic research administration systems, protocol management platforms, reporting workflows, and investigator training programs to accommodate newly covered activities and revised review pathways.
The final policy should explicitly allow institutions to implement scalable oversight models based on institutional size, research portfolio, and organizational complexity. A one-size-fits-all approach may be difficult to implement across large academic medical centers, multi-campus systems, and institutions with extensive clinical and translational research programs.

To facilitate a smooth transition to the new Guidelines, we recommend:
1. Standardized risk-assessment, protocol-registration, delegated-review, incident-reporting, and meeting-minutes templates.
2. Examples spanning basic science, translational work, animal research, clinical research, BSL-3 facilities, and Select Agent programs.
3. Clear guidance on the transition of existing approvals, including whether they remain valid until their current expiration or require reassessment.
4. Training materials and model institutional policies, including examples of acceptable delegation and quality assurance.
5. A central source for authoritative interpretations, with defined response targets for requests for containment determinations.
6. A formal opportunity to evaluate implementation problems and revise guidance after institutions have practical experience with the new system.
7. The current biosafety framework should remain valid during and throughout any transitition period until the new framework becomes effective.

Request for Comment: Draft NIH Biosafety Policy for Research Involving Biohazards

NOT-OD-26-112

Institution Name: University of North Carolina at Chapel Hill

Point of Contact: Doug Cyr, IBC Chair and Professor of Cell Biology and Physiology

Comments on Draft NIH Biosafety Framework

As an Institutional Biosafety Committee (IBC), we support NIH's effort to modernize the Guidelines and better align oversight with biological risk beyond recombinant and synthetic nucleic acid research. We believe the success of any expanded framework will depend not only on identifying additional biological hazards, but also on ensuring that oversight remains risk-based, scalable, and administratively sustainable. Expanded scope should be accompanied by clear applicability criteria, exemptions where appropriate, delegation authorities, and implementation flexibility so that IBCs can focus limited expertise and resources on activities presenting meaningful biosafety risk.

Question 1: Is the scope appropriate? Are there gaps or overly broad definitions of biohazards?

The proposal addresses circumstances in which risks may arise outside the current rsNA-centered framework in that substantial biological risks can arise from wild-type agents, primary specimens, prions, toxins, and other materials that do not necessarily involve recombinant or synthetic nucleic acids. However, the draft's scope raises several questions.

- **Primary human materials and clinical specimens.** The draft specifically includes primary cells that may contain adventitious agents. NIH should clarify when routine use of human tissues, blood, diagnostic specimens, and established clinical specimen workflows constitutes research requiring IBC approval, as opposed to activities already managed through institutional exposure-control, laboratory safety, and clinical policies.
- **Well-characterized cell lines and biological reagents.** The draft includes well-characterized cell lines in the delegated-review category, yet the definition of covered biohazards and the conditions for determining that a line presents negligible risk need to be explicit. Otherwise, work that has historically required little or no separate committee attention may generate additional registrations.
- **Toxins and self-aggregating proteins.** The draft defines toxins as proteins or peptides produced by living organisms that cause harm in humans. NIH should clarify the intended treatment of

nonprotein toxins, synthetic or chemically modified biological products, nonpathogenic model systems involving disease-associated proteins, and proteins whose risks are not equivalent to those of infectious agents.

- **Research boundaries.** Clarify how the policy applies to diagnostic testing, quality-control work, clinical laboratory operations, teaching, core facilities, repository activities, and incidental handling of specimens when those activities intersect with biomedical research.

We support expanding biosafety oversight to encompass biological hazards that may not involve recombinant or synthetic nucleic acids. We recommend that NIH provide more precise scope definitions, including examples of activities that require registration or review and activities that may be managed under existing institutional programs without a separate IBC submission. The policy should clearly distinguish research involving a meaningful biological hazard from routine clinical, diagnostic, educational, and laboratory activities that do not present a comparable risk. NIH should also clarify how the policy applies to non-NIH-funded work across institutions with funding from non-Federal sources.

While we support a broader risk-based biosafety framework, the proposed scope could substantially increase the volume of protocols requiring registration, administrative review, and committee oversight. Without clearer boundaries, institutions may default to submitting a wide range of low-risk activities for IBC review to ensure compliance. This could divert limited committee and biosafety professional resources away from higher-risk research activities and ultimately reduce the effectiveness of oversight. NIH should ensure that expanded scope is accompanied by clear exclusions, exemptions, and risk-based screening mechanisms that prevent unnecessary administrative burden while maintaining appropriate biosafety protections.

Question 2: Is the proposed tiered oversight structure appropriate and calibrated to risk?

We support risk-tiered oversight and delegation of appropriate reviews. To achieve the stated goal of reducing administrative burden, NIH should define the criteria that distinguish full IBC review from delegated review and administrative screening. Institutions should be permitted to establish documented, risk-based procedures for routine activities and amendments, subject to IBC oversight and escalation when risk changes. The framework should focus committee attention on activities with meaningful biosafety uncertainty or consequence rather than on the number of registrations generated.

We recommend the NIH:

- Establish explicit criteria for full committee review, delegated review, administrative screening, and exemption from separate IBC review.
- Permit documented, institutionally approved risk-triage procedures rather than requiring a separate registration for every covered material or activity.

- Allow the IBC to approve a defined research scope with clearly specified boundaries, so that scientifically equivalent amendments do not repeatedly trigger full review.
- Permit institutional biosafety professionals to perform routine oversight and verify compliance under written IBC-delegated authority.
- Clarify whether and how protocols can be reviewed jointly, or cross-referenced, when they involve the same or equivalent agents, facilities, personnel, and containment controls.
- Explicitly recognize that existing institutional programs, including occupational health, laboratory safety, bloodborne pathogen, clinical laboratory, and animal care programs, may serve as equivalent oversight mechanisms for certain low-risk activities.

Question 3: Should Risk Groups remain the baseline, or should Biosafety Levels become the primary classification?

Risk Groups and Biosafety Levels should remain complementary components of the framework. RG classifications provide a useful baseline for intrinsic agent risk, while BSL/ABSL determinations must reflect the specific procedures, modifications, exposure routes, biological systems, and containment capabilities involved. NIH should provide consistent decision criteria and timely determinations for novel or uncertain agents, while preserving institutional authority to impose more protective controls based on local risk assessments.

Question 4: Are compliance and enforcement mechanisms effective? How should NIH encourage voluntary compliance and address biosecurity?

We support effective compliance mechanisms that reinforce institutional accountability and encourage timely reporting. We recommend a graduated corrective-action framework that distinguishes administrative deficiencies, promptly corrected deviations, and serious or repeated biosafety violations. NIH should harmonize reporting requirements with other applicable federal programs, define reportability thresholds clearly, and establish standardized protections for sensitive information. A de-identified, nonpunitive system for learning from near-misses would strengthen biosafety culture and improve the quality of incident data.

Compliance requirements should be calibrated to risk and should avoid creating reporting expectations that disproportionately burden institutions while providing limited biosafety benefit. Excessive reporting of low-risk administrative deviations could obscure identification of significant biosafety concerns and discourage timely reporting of minor events and near-misses. Providing processes for variances from NIH policy including providing institutions with a notice of non-compliance, an opportunity to respond to such a notice, and a challenge or appeal process would also drive reporting compliance.

Question 5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates.

Transparency should make oversight understandable and accountable without making public records a source of additional safety or security risk. The current NIH framework already includes public-facing IBC minutes with content requirements recently updated. Public release of incident reports should serve to inform the public and institutional personnel such that policies and procedures can be improved without risking the release of sensitive personal or research data. Minor and near-miss incidents should generally remain subject to internal institutional review rather than public reporting requirements, thereby encouraging timely reporting and corrective action. Annual aggregate data of reported near misses, or summaries of events, could be reported to allow for learning form made mistakes.

Incident reporting requirements should balance transparency with administrative feasibility. Public reporting requirements that are overly broad, duplicative, or insufficiently risk-based may require significant institutional resources while providing limited additional value for biosafety improvement. Reporting structures should focus on incidents with meaningful biosafety or public health significance, while allowing institutions flexibility to manage minor events and near-misses through internal corrective-action processes.

To facilitate the release of information, we recommend the NIH establishes:

- A uniform definition of the information that must appear in public minutes.
- Explicit rules for redacting protected health information, identifiable employee information, confidential research details, and sensitive security information.
- A standard procedure for institutional review before publication, including who makes the redaction determination and how disagreements are resolved.
- Clear expectations for the treatment of incidents involving multiple protocols, departments, or facilities.
- A practical publication schedule that accounts for incident investigation, institutional review, and required agency coordination.
- Standardized templates that do not inadvertently compel institutions to disclose more sensitive information than necessary.

Question 6: What implementation resources and additional guidance are needed?

Successful implementation will require more than publication of a final policy. NIH should provide a detailed policy implementation guide, standardized templates, model procedures, examples for complex research settings, and authoritative guidance for recurring questions. We recommend a phased implementation approach, explicit transition rules for existing approvals, and an evaluation period that

allows institutions and NIH to identify unintended burdens or gaps before additional requirements are imposed.

The draft anticipates implementation six months after publication of the final policy. It also contemplates additional guidance on IBC functions, RG classifications, containment, occupational health, and selected high-risk research categories.

Six months is likely insufficient to inventory newly covered activities, revise policies and electronic systems, train investigators and committee members, and update public-facing reporting procedures. With an appreciation for the extensive nature of the changes proposed, a 12-to-24-month period would allow for a well planned and executed implementation.

NIH should conduct and publish an assessment of the anticipated administrative impact of the revised Guidelines, including estimated increases in protocol registrations, review volume, incident reporting, training requirements, and staffing needs. Many IBCs operate with limited administrative support and biosafety staffing. Expansion of review responsibilities without corresponding flexibility, delegation authority, or additional resources may create challenges for timely protocol review and effective oversight.

Institutions will likely need substantial modifications to electronic research administration systems, protocol management platforms, reporting workflows, and investigator training programs to accommodate newly covered activities and revised review pathways.

The final policy should explicitly allow institutions to implement scalable oversight models based on institutional size, research portfolio, and organizational complexity. A one-size-fits-all approach may be difficult to implement across large academic medical centers, multi-campus systems, and institutions with extensive clinical and translational research programs.

To facilitate a smooth transition to the new Guidelines, we recommend:

1. Standardized risk-assessment, protocol-registration, delegated-review, incident-reporting, and meeting-minutes templates.
2. Examples spanning basic science, translational work, animal research, clinical research, BSL-3 facilities, and Select Agent programs.
3. Clear guidance on the transition of existing approvals, including whether they remain valid until their current expiration or require reassessment.
4. Training materials and model institutional policies, including examples of acceptable delegation and quality assurance.

5. A central source for authoritative interpretations, with defined response targets for requests for containment determinations.
6. A formal opportunity to evaluate implementation problems and revise guidance after institutions have practical experience with the new system.
7. The current biosafety framework should remain valid during and throughout any transitition period until the new framework becomes effective.

Conclusion

Overall, we support modernization of the NIH Guidelines and the transition toward a broader biological-risk framework. To be effective, however, the final framework should maintain a clear connection between oversight intensity and actual risk. Expanded scope without corresponding exemptions, delegation mechanisms, and implementation flexibility may substantially increase administrative workload for investigators, biosafety professionals, and IBCs without proportionate biosafety benefit. A successful framework should enable institutions to direct oversight resources toward higher-risk and novel research while allowing routine, well-understood activities to be managed through streamlined processes and existing institutional safety programs.

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): infectious disease pathogenesis and epidemiology

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy fails to define all necessary aspects of biohazards and oversight, using vague language throughout. It is an acceptable first draft, but is not an actionable policy.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): It is an acceptable first draft, but is not an actionable policy. The tiered oversight needs to be better defined and currently creates increased administrative burden that may not always be clearly a risk-based oversight policy.

3. Continued utility of Risk Groups: The way it is written, this proposed policy does not seem to create a clear risk-based oversight, but instead generates higher administrative burden.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft incident report and mandate for this to be public is damaging to all involved. Many researchers conduct very specialized studies. Even a report that removes all identifying names would still be easily traced to the research team and could lead to poor outcomes for any involved individuals. For example, if the name of a PI is not allowed to be redacted and you state a graduate student was exposed, someone could easily find the PI's website, learn they only have one graduate student, and harrass that student. That is not a scenario we should allow to occur.

6. Other feedback relevant to this resource: It is an acceptable first draft, but is not an actionable policy in the current format. Terms, requirements, timelines need to be fully defined, the current draft depends on vague language. I have concerns surrounding the vague language particularly as it relates to BSL-3/ABSL-3: "Any incident at BSL-3/ABSL-3" is too vague to be actionable. . There are also concerns around the short timeline for reporting certain things (for example, does the timeline start from the moment of the incident, or the moment the incident is first reported to leadership, or something else?), and for the need to submit incident reports for "Potential releases involving facility and/or equipment failures, even when redundant systems were functioning properly, to address the possibility of risk to personnel and

the community and prevent future occurrences" as this seems to indicate that we'd need to submit incident reports when testing that our redundant systems as part of regular maintenance.

518. Vicente Zuno Fernández

I am responding: On behalf of myself

Name: Vicente Zuno Fernández

Name of Organization: Houston Methodist Research Institute

Type of Organization: Non-Profit Research Organization

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): HMRI is a multidisciplinary biomedical research institution emphasizing the translation of laboratory discoveries into clinical applications.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The expanded scope of the policy is generally appropriate and reflects the need for comprehensive, risk-based biosafety oversight. However, clearer definitions and boundaries are necessary to ensure consistent implementation without imposing unnecessary administrative burdens on low-risk research. In particular, the definition of genetic modification should distinguish permanent genetic alterations from transient nucleic acid expression, such as mRNA-based applications. Replacing the detailed NIH Guidelines with a substantially abbreviated policy, without retaining established exemptions, examples, and interpretative guidance, create uncertainty regarding which activities require oversight and at what level. NIH should clearly distinguish exempt activities, delegated reviews, and full IBC reviews, while establishing consistent, risk-based criteria that prevent oversight gaps without unnecessarily expanding regulatory requirements.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered, risk-based oversight framework is appropriate, provided that responsibilities between federal agencies and local institutions are clearly defined. Local IBCs and BSOs should retain authority to assess and manage routine research activities based on institution-specific risks, while federal oversight should focus on higher-risk research, significant incidents, and activities requiring specialized review. The policy should establish clear criteria for escalating oversight, preserve institutional flexibility, and avoid duplicative administrative requirements. Additionally, federal expectations should be proportional to the actual biological risks involved rather than imposing uniform requirements across all research activities.

3. Continued utility of Risk Groups: Risk Groups (RGs) remain valuable as a baseline for biological risk assessment and should be retained within the proposed policy. However, RG classifications alone are insufficient to determine appropriate containment, particularly when organisms undergo genetic modifications that may alter pathogenicity, transmissibility, host range, or other biological characteristics. Biosafety Levels (BSLs), as described in the BMBL, provide a more comprehensive, activity-based framework that considers agent characteristics, experimental procedures, exposure potential, and available safeguards. NIH should preserve the distinction between RG classifications and

BSL containment requirements while emphasizing comprehensive, risk-based assessments conducted at the institutional level. This approach would provide flexibility without compromising biosafety or introducing unnecessary regulatory complexity.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary compliance by providing accessible guidance, standardized risk assessment tools, training resources, and model institutional policies. Voluntary adoption should remain flexible and risk-based, particularly for smaller institutions with limited biosafety resources. Clear distinctions between mandatory requirements and recommended practices would promote broader participation without creating unnecessary administrative or financial burdens.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The proposed templates may improve consistency and transparency but should remain flexible and proportional to risk. Incident reporting should clearly distinguish events requiring immediate notification from those appropriate for routine institutional documentation. Reporting requirements should avoid duplicating information already captured through institutional incident management systems. Similarly, IBC meeting minutes should document substantive discussions and decisions without imposing excessive administrative burdens. Public disclosure requirements should adequately protect confidential research information, personnel privacy, and institutional security.

6. Other feedback relevant to this resource: NIH should provide comprehensive implementation guidance, including standardized risk assessment tools, clearer definitions, practical examples, and decision-making frameworks for determining oversight requirements. Additional guidance is particularly needed regarding BSO qualifications and responsibilities, IBC review thresholds, incident reporting criteria, and the distinction between mandatory requirements and recommended practices. Retaining relevant examples and interpretations from the existing NIH Guidelines would promote consistency and reduce uncertainty. NIH should also provide adequate transition periods, training resources, and technical assistance to support implementation without imposing unnecessary administrative burdens.

Uploaded File: Comments-for-Submission-Draft-NIH-Biosafety-Policy-10.7.2026-1.pdf

Description: Vicente Zuno - Comments for Submission - Draft NIH Biosafety Policy

October 7, 2026

Dear NIH OSP,

I appreciate the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards. I submit these comments in my individual capacity as a biosafety professional with experience supporting IBC oversight, conducting biological risk assessments, investigating laboratory incidents, inspecting containment laboratories, and advising investigators.

I support NIH's effort to modernize biosafety oversight, expand the framework beyond recombinant and synthetic nucleic acid research, and establish a more risk-based system. However, several areas would benefit from clarification or additional guidance:

1. Qualifications and Competency Requirements for Biological Safety Officers

I strongly recommend that NIH establish minimum competency expectations for Biological Safety Officers (BSOs).

The draft assigns BSOs significant technical responsibilities, including inspection of containment facilities and equipment, assessment of compliance, investigation of incidents, identification of violations, and technical advice to investigators and the IBC. These functions require specialized knowledge and professional judgment, yet the draft specifies no minimum education, training, experience, or competency requirements.

NIH should establish a competency-based framework addressing areas such as biological risk assessment, containment, laboratory practices, incident investigation, applicable standards, and IBC oversight. Institutions could retain flexibility in demonstrating competency through education, experience, training, professional credentials, or a combination thereof.

2. Assignment of BSO Responsibilities to an "Other Official"

I am particularly concerned by the provision stating that, if an institution does not designate a BSO, another official must assume the BSO's responsibilities.

These responsibilities remain technical regardless of the title of the individual performing them. Incident investigation, containment assessment, laboratory inspection, and technical recommendations to an IBC require appropriate expertise.

NIH should remove this provision or clarify that any individual performing BSO functions must meet equivalent competency expectations. Otherwise, the Policy risks creating significant variability in the qualifications of those responsible for institutional biosafety oversight.

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

3. Circumstances Requiring Appointment of a BSO

NIH should reconsider limiting mandatory BSO appointment primarily to institutions conducting BSL-3/BSL-4 research or research involving GDMOs.

The proposed Policy expands biosafety oversight to wild-type biological agents, toxins, primary cells, and other biohazards. An institution could maintain a substantial BSL-2 program involving human pathogens while having significant responsibilities under the Policy without being required to designate a BSO.

NIH should either broaden the circumstances requiring a qualified BSO or provide criteria based on the size, complexity, and risk profile of an institution's research program.

4. Qualifications and Procedures for Delegated IBC Review

I support delegated review for appropriate lower-risk research, but additional guidance is needed regarding who may perform these reviews and under what conditions.

NIH should clarify whether delegated reviewers must be voting IBC members, whether a BSO may independently conduct delegated review, minimum reviewer competency, conflict-of-interest requirements, documentation expectations, and circumstances requiring elevation to full committee review.

A model delegated-review procedure would improve consistency among institutions while preserving institutional discretion to apply more restrictive review standards.

5. Activities Outside the Policy and Removal of Existing Exemptions

The draft identifies certain activities as outside the Policy but does not provide an exemption structure comparable to the current NIH Guidelines.

Clear boundaries are essential to prevent unnecessary administrative burden and inconsistent interpretation. NIH should develop a decision framework distinguishing:

- Activities outside the Policy;
- Activities not requiring IBC review;
- Activities eligible for delegated review;
- Activities requiring full IBC review; and
- Activities requiring both NIH and IBC review.

Representative examples of commonly conducted biomedical research would be particularly useful.

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

6. Incident-Reporting Thresholds and Public Posting

Additional guidance is needed to distinguish incidents requiring NIH reporting from those that may be managed institutionally.

Terms such as “minor spill,” “low-risk agent,” “breach of containment,” and “significant risk to human health” may be interpreted differently among institutions. NIH should provide a decision tree and representative examples identifying events requiring immediate NIH reporting, routine reporting, internal review only, or no formal reporting.

NIH should also establish clear standards for redacting publicly posted incident reports to protect personal and medical information, confidential research information, security-sensitive facility information, and ongoing investigations.

7. Relationship Between Risk Groups and Biosafety Levels

I encourage NIH to retain Risk Groups as one component of biological risk assessment while providing clearer guidance regarding their appropriate use.

Risk Group and Biosafety Level are not interchangeable. Risk Group describes characteristics of a biological agent, whereas containment level should result from a protocol-specific risk assessment considering the agent, procedures, concentration, volume, exposure routes, aerosol generation, animal models, genetic modifications, and other experimental factors.

Because confusion between RG classification and BSL assignment remains common, the new Policy provides an opportunity to clearly distinguish these concepts and reinforce protocol-specific risk assessment.

8. Implementation Guidance and Transition Period

The proposed Policy represents a substantial change in institutional biosafety oversight. Institutions may need to revise committee jurisdiction, procedures, electronic systems, delegated-review processes, incident-reporting procedures, institutional websites, training, and existing research registrations.

NIH should make implementation resources available well before the effective date. Particularly useful resources would include:

- A model Institutional Biosafety Assurance;
- A model IBC charter;
- A biosafety registration template;
- A delegated-review procedure;

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

- Scope and review-category decision trees;
- Incident-reporting guidance;
- BSO competency guidance;
- IBC and reviewer training materials;
- Public disclosure and redaction guidance; and
- Transition guidance for existing research.

These resources would be especially valuable to smaller institutions without dedicated biosafety or regulatory personnel.

9. Definition of Genetic Modification

I recommend that NIH revise or clarify the proposed definition of "genetic modification."

The draft includes introduction of nucleic acid molecules that "can be transcribed or translated." Transcription or translation alone, however, does not necessarily result in a stable or heritable genetic alteration.

For example, transient introduction of mRNA can result in translation of an encoded protein without altering the cellular genome. Likewise, non-integrating nucleic acid constructs may produce transient expression without creating a stable genetic modification.

NIH should clarify whether transient nucleic acid expression is intentionally being classified as "genetic modification." If such research is intended to remain within the Policy, terminology should distinguish transient nucleic acid expression from stable genomic modification. If not, the definition should be revised accordingly.

Clear terminology is essential because this definition directly affects whether research falls within the Policy and what oversight is required.

10. Clarity and Proportionality in Compliance and Enforcement

The proposed Policy includes potentially significant consequences for noncompliance, including additional terms and conditions, termination, and effects on future NIH funding decisions. Given the breadth of the Policy and its transition from detailed Guidelines to a more streamlined framework, NIH should clearly explain how compliance and enforcement determinations will be made.

NIH should clarify:

- How inadvertent or good-faith interpretive errors will be distinguished from serious, repeated, reckless, or intentional noncompliance;

Disclaimer: This submission reflects my personal views and professional experience and does not represent the official position or policies of my employer or any affiliated institution.

- Whether institutions will ordinarily have an opportunity to implement corrective actions before severe enforcement measures;
- What factors will determine the severity of an enforcement response;
- How actual or potential biosafety risk will influence enforcement; and
- How NIH will address provisions reasonably subject to more than one interpretation.

A risk-based biosafety policy should be accompanied by a risk-based and proportionate compliance framework. Clear enforcement principles would encourage self-identification and correction of problems while reducing the risk of disproportionate consequences for ambiguous or low-risk compliance issues.

Conclusion

The proposed NIH Biosafety Policy is an important opportunity to modernize biological research oversight, but its success will depend on clear scientific terminology, qualified biosafety professionals, and sufficiently detailed implementation and enforcement guidance.

As NIH expands institutional responsibilities, it should establish appropriate competency expectations for BSOs and others performing BSO functions. Key definitions, including "genetic modification," should also be scientifically precise and avoid unintentionally capturing activities that do not constitute stable genetic alteration.

Finally, simplification of the current NIH Guidelines should not eliminate the examples and distinctions institutions need to understand their obligations. Where noncompliance may carry significant funding consequences, institutions should be able to determine prospectively what the Policy requires. A risk-based biosafety policy should therefore be supported by clear implementation guidance and a proportionate, risk-based compliance framework.

Thank you for considering these comments.

Vicente Zuno, RBP (ABSA), CPH (NBPHE) – Provisional

Type of Organization: Non-Profit Research Organization

Role: Other

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed scope would benefit from greater precision to support consistent application across varied institutional settings. The final policy should define “research” and “biohazard” clearly and distinguish covered research from clinical diagnostics, public-health testing, assay verification and validation, routine analytical testing, product-support testing, and other activities that use biological materials without seeking generalizable knowledge. Terms such as “potential,” “acceptable,” and “significant risk” should be accompanied by objective criteria, a decision tree, and representative examples for academic, contract-research, analytical, and public-health settings.

Institutions also should be able to rely on reasonable, documented classification decisions made in good faith under then-current NIH criteria and examples (eg the NIH Guidelines Appendices A and B), unless the decision was based on a material omission or is affected by new information or a material change in the work.

NIH should clarify the organizational boundaries of a covered institution, the meaning of research “sponsored by” an institution, and the treatment of affiliates, subsidiaries, separately incorporated locations, subrecipients, subcontractors, and client-sponsored activities. Potential oversight gaps involving recombinant plant and plant-pathogen research should be addressed through risk-based criteria developed in coordination with USDA or another appropriate federal agency.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered system is appropriate if federal oversight establishes clear minimum requirements while preserving local authority to apply project-specific judgment. Federal review or mandatory standards should focus on activities involving substantial hazards, novel agents, high uncertainty, or national-security implications. Institutions should be able to use documented administrative or delegated review for well-characterized, low-risk activities and reserve full IBC review for work whose hazards, uncertainty, or proposed controls warrant committee deliberation.

The final policy should identify the federal authority responsible for administering an expedited process

for emerging, novel, or zoonotic agents when no current risk-group recommendation exists. That process should include interim containment recommendations, defined submission requirements, points of contact, decision timelines, and time-limited emergency determinations so that appropriately qualified laboratories can perform urgent diagnostic, assay-development, and countermeasure work under defined minimum controls.

NIH should specify which project-review requirements are satisfied by equivalent federal oversight and which institution-level obligations—such as assurance, reporting, training, recordkeeping, and public posting—remain applicable.

3. Continued utility of Risk Groups: Risk Groups remain a useful baseline for understanding the intrinsic hazards of agents and should be preserved in an authoritative, publicly accessible federal resource. They should not, however, be treated as a stand-alone containment determination, particularly when an agent is genetically modified. Institutional risk assessment should consider whether a modification may alter host range, pathogenicity, transmissibility, environmental stability, treatment susceptibility, toxin production, or other relevant characteristics, and should select practices, equipment, and facility controls using the BMBL.

NIH has stated that implementation resources will draw from current Risk Group classifications and other existing guidance. The final policy should expressly preserve those resources (eg NIH Guidelines Appendix B) until authoritative replacements are published, clarify the relationship between RG and BSL, maintain a searchable record of generally applicable determinations for previously reviewed experiment types, and confirm that existing approvals remain valid unless new information or a material change warrants reassessment.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): Voluntary compliance is most likely when NIH offers practical tools and clear incentives rather than extending mandatory requirements indirectly. Useful resources would include modular model policies, decision tools, training materials, sample risk assessments, and adaptable templates that institutions may adopt without becoming subject to unrelated funding requirements.

A tiered recognition or self-attestation program, confidential technical assistance, and access to the centralized incident-learning system would further encourage participation. NIH also should make clear how voluntary adoption affects an institution's legal and programmatic obligations, including that use of NIH tools or templates does not by itself create additional public-disclosure duties or implied certifications beyond the practices expressly adopted.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Appropriate reporting and accountability for significant biosafety incidents and compliance failures is critical to promoting transparency and trust. The templates should identify minimum data elements while allowing institutions to use equivalent records and systems. The incident-learning function should encourage timely reporting, root-cause analysis, corrective action, and sector-wide learning, while preserving appropriate enforcement for willful misconduct, material nondisclosure, or repeated noncompliance.

The proposed National Biosafety Data and Safety Analysis Center could advance those objectives by

aggregating, de-identifying, and analyzing incident and near-miss data. NIH should use that centralized mechanism as the principal vehicle for public learning. Institutional reporting should support transparency, accountability, and corrective action, while institution-level public posting should be limited to information that can be disclosed without compromising privacy, security, legal obligations, proprietary information, or client confidentiality.

Although the draft contemplates allowable redactions, NIH should establish objective withholding and redaction standards so transparency obligations are applied consistently and do not inadvertently create safety, security, privacy, or legal risks. Institutions should not be required to publish information that could identify personnel or facilities, compromise physical security, cybersecurity, personnel safety, or appropriate access controls, disclose restricted or classified information, conflict with applicable legal or sponsor restrictions, interfere with an investigation, or expose proprietary research information. Public outputs should focus on aggregate trends, lessons learned, contributing factors, corrective actions, and other information that advances public understanding without increasing operational or security risk.

The meeting-minutes template should document attendance, quorum, recusals, risk determinations, required controls, votes, and action items without requiring sensitive protocol details to be reproduced in public-facing records. It should allow restricted information to be reviewed by an authorized subset or designated official and referenced in non-sensitive minutes. NIH should also clarify how public-posting requirements interact with the Federal Select Agent Program, classified and controlled information requirements, privacy obligations, contractual restrictions, law-enforcement activities, and other applicable federal requirements.

6. Other feedback relevant to this resource: Additional implementation resources will be important to the clarity, consistency, and scalability of the future national framework. NIH should provide a scope decision tree; examples distinguishing research from diagnostics, validation, analytical, and product-support activities; extend the institutional requirement for biosafety officers to BSL-2 laboratories; establish baseline competence requirements for biosafety officers, individuals designated by the institution to fulfill the responsibilities of a biosafety officer, and individuals delegated to review and approve low-risk research; risk-tiering and delegated-review criteria; an expedited pathway for emerging agents; and a maintained resource for RG assignments and generally applicable determinations for previously reviewed experiments.

Guidance is also needed on institutional applicability, organizational boundaries, subawards and subcontracts, client-funded work, amendment thresholds, grandfathering, de novo renewals, review timelines, training documentation, institutional registration, PI and biosafety-official responsibilities, multi-site programs, and the relationship to Select Agent, USDA, biosecurity, classified, and other access-control requirements. The final policy should allow equivalent institutional systems and documentation when they satisfy the substantive requirements.

The draft proposes an effective date six months after publication of the final policy. NIH should consider whether that period is sufficient for institutions with large portfolios, multiple sites, or high volumes of short-duration projects, and whether a longer or phased implementation period with prioritized milestones would better support orderly implementation. Existing approvals should remain valid during transition unless new information or a material change warrants reassessment.

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Since Risk Group assignments are not provided in the BMBL, my recommendation is to only require assigning biosafety levels rather than assigning both risk groups and biosafety levels. If risk group assignment is required, I recommend retaining and expanding Appendix B and providing a definitive source or clear criteria for assigning Risk Groups. Without standardized Risk Group classifications, institutions may reach different conclusions for the same agent, reducing consistency across the research community.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The policy requires institutions to post incident reports on their website using the NIH template that includes the PI's name. I believe this may discourage incident reporting and, in a small laboratory with few researchers, potentially identify the affected individual with the amount of detail required in the template. I recommend that the requirement for the name of the PI name and grant numbers be removed from the posted incident report.

6. Other feedback relevant to this resource: It's not clear if my attachment uploaded. Therefore, I'm providing all of my comments in this section to ensure you receive them.

1. Posting incident reports with PI's name on institutions' website
The policy requires institutions to post incident reports on their website using the NIH template that includes the PI's name. I believe this may discourage incident reporting and, in a small laboratory with few researchers, potentially identify the affected individual with the amount of detail required in the template. I recommend that the requirement for the name of the PI name and grant numbers be removed from the posted incident report.

2. Three-year de novo review
The draft policy indicates IBC approval may not exceed three years, after which the investigator must submit a de novo registration for review. I believe a 5-year de novo review is more appropriate to coincide with the typical five year funding cycle. Requiring a PI to annually renew their IBC registration will ensure PIs are continually reminded that an amendment must be submitted for additional planned work not covered under the original registration. In addition, a provision for extending work past the 5-year expiration at the discretion of a delegated member or biosafety officer, would allow accommodation for extenuating circumstances. If the three year de novo requirement remains, then registrations currently approved for five years should be grandfathered in to allow renewal at the end of their current cycle. Doing otherwise, would create an enormous administrative burden and potentially rushed reviews of de novo registrations.

3. Exemptions of very low-risk research
The proposed draft does not include a list of exemptions for very low-risk research. I recommend retaining the current list of exemptions in the NIH Guidelines and adding further exemptions for the following:
• Well characterized tissue-culture cells genetically modified with recombinant or synthetic nucleic acid molecules, provided that the modification does not introduce or produce an infectious biological agent, biological toxin, gene-drive system, or other biological hazard covered by the policy.
• Caenorhabditis elegans and Drosophila melanogaster when the modification does not introduce a biohazard, such as, a biological agent, toxin, gene-drive system, increased pathogenicity, or increased transmissibility.
• Escherichia coli BL21

4. Toxins
I recommend retaining the current NIH Guidelines threshold of a human LD50 of less than 100 nanograms per kilogram body weight and excluding plant-derived toxins that are not on the select agent list. Toxins behave like chemicals and typically fall under the purview of chemical safety programs (with the exception of select agent toxins).

5. Review of primary cells
I recommend that recombinant and wild type primary cells are permitted delegated since these materials may contain RG2 agents which are permitted delegated review. If the primary cells are suspected of containing an RG3 or RG4 agent, then full committee review would be appropriate.

6. Clarifications
Please clarify the following:
a. Exemption of CAR T-cells from clinical research coverage due to their low risk
b. That the very rare occurrence of opportunistic or nosocomial disease does not necessarily bring an otherwise RG1 wild-type agent within the scope of the policy.
c. Whether HIV, hepatitis viruses, and other bloodborne pathogens potentially present in primary materials are considered adventitious agents

d. Whether mRNA, microRNA, miRNA mimics etc. in animals are permitted delegated review
e. Whether RG2 agents only expressing reporter genes are permitted delegated review

Description: Comments

522. The University of Sydney

I am responding: On behalf of an organization

Name: Lan Le

Name of Organization: The University of Sydney

Type of Organization: Academic Institution

Role: Other

Role - Other: Biosafety

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Section II applies the Policy to non-NIH-funded research at any institution receiving any NIH funding, and the Compliance and Enforcement provisions require institutions, as a term and condition of NIH funding, to ensure that all research conducted at or sponsored by them complies, whatever the funder. This is a significant change for institutions outside the United States. Under the current NIH Guidelines, the institution-wide requirement applies to research within the U.S. and its territories (Section I-C-1-a), while research performed abroad is covered only where it is supported by NIH funds or involves human testing of NIH-developed materials (Section I-C-1-b), and must comply with host-country rules where they exist (Section I-C-1-b-(3)).The University recognises that the Policy provides a sound framework of fundamental biosafety principles and practices for biomedical research, particularly as a model for institutions outside existing regulatory frameworks. However, it is not clear whether the Policy applies to foreign institutions that collaborate with a U.S. institution receiving NIH funding, or that receive NIH funding and conduct the research outside the U.S. The Draft also does not define “sponsored by” or “at the institution” or say whether an institution that receives NIH funds only as a subaward “receives any NIH funding”. As currently drafted, the Policy would cover an institution’s entire research portfolio, not just the NIH-funded work.

For a large Australian university such as ours, this means a single NIH award could bring work funded by our National Health and Medical Research Council, the Australian Research Council, the Medical Research Future Fund and industry under NIH terms. It could also reach facilities shared with affiliated hospitals and research institutes that the university cannot contractually bind.

Recommendation: We ask NIH to limit mandatory scope to only NIH-supported projects and the laboratories where they are conducted, to define "sponsored by" and "at the institution" (including affiliates, adjuncts and shared facilities), to clarify whether subaward-only funding brings an institution within scope, and to leave wider adoption to the voluntary provisions.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The University supports the Policy's principle of tiered oversight calibrated to risk. The main gap for an Australian institution is that the Policy does not recognise foreign regulatory systems. The import, export, use, storage and transport of biological materials in Australia are already governed by Federal and State legislation, regulatory schemes, and technical standards. These protect Australian public health and safety, prevent the introduction and spread of infectious diseases and pests, safeguard the environment and give effect to Australia's international treaty obligations. Non-compliance carries serious consequences including suspension of research, loss of licences and permits, and criminal penalties. Most of the Policy's scope therefore already has a regulated counterpart in Australia, as the table below shows. Requiring foreign institutions to meet both systems would duplicate processes for the same work without improving safety and runs against the Draft's stated aim of reducing red tape.

The current NIH Guidelines already recognises this. Section I-C-1-b(3) provides that, for NIH-supported research performed abroad, if the host country has established rules for the conduct of recombinant or synthetic nucleic acid research, the research must comply with those rules; only where the host country has no such rules must the research be reviewed by an NIH-approved Institutional Biosafety Committee or equivalent body and accepted by the host country's national authority. The Draft Policy contains no equivalent provision. Australia's Gene Technology Act 2000 already requires accredited organisations to operate Institutional Biosafety Committee under the Regulator's guidelines, so the oversight structure NIH seeks already exists in Australian law.

As currently drafted, research that falls under the "purview of another federal agency" may proceed under that agency's oversight, but this appears limited to U.S. agencies. We ask NIH to extend this recognition to foreign institutions operating within mature, nationally regulatory frameworks, such as Australia's, where equivalent oversight mechanisms already exist.

Recommendation: We ask NIH to retain the host-country deference in Section I-C-1-b(3) of the current NIH Guidelines and to establish an equivalency or foreign assurance pathway, under which institutions may certify compliance with their national biosafety law while committing to the Policy's core principles, including risk assessment before work begins, proportionate biosafety oversight using a tiered review approach, and appropriate containment and approval requirements.

3. Continued utility of Risk Groups: The University supports the Policy's principle of tiered oversight calibrated to risk. The main gap for an Australian institution is that the Policy does not recognise foreign regulatory systems. The import, export, use, storage and transport of biological materials in Australia are already governed by Federal and State legislation, regulatory schemes, and technical standards. These protect Australian public health and safety, prevent the introduction and spread of infectious diseases and pests, safeguard the environment and give effect to Australia's international treaty obligations. Non-compliance carries serious consequences including suspension of research, loss of licences and permits, and criminal penalties. Most of the Policy's scope therefore already has a regulated counterpart in Australia, as the table below shows. Requiring foreign institutions to meet both systems would duplicate processes for the same work without improving safety and runs against the Draft's stated aim of reducing red tape.

The current NIH Guidelines already recognises this. Section I-C-1-b(3) provides that, for NIH-supported

research performed abroad, if the host country has established rules for the conduct of recombinant or synthetic nucleic acid research, the research must comply with those rules; only where the host country has no such rules must the research be reviewed by an NIH-approved Institutional Biosafety Committee or equivalent body and accepted by the host country's national authority. The Draft Policy contains no equivalent provision. Australia's Gene Technology Act 2000 already requires accredited organisations to operate Institutional Biosafety Committee under the Regulator's guidelines, so the oversight structure NIH seeks already exists in Australian law.

As currently drafted, research that falls under the "purview of another federal agency" may proceed under that agency's oversight, but this appears limited to U.S. agencies. We ask NIH to extend this recognition to foreign institutions operating within mature, nationally regulatory frameworks, such as Australia's, where equivalent oversight mechanisms already exist.

Recommendation: We ask NIH to retain the host-country deference in Section I-C-1-b(3) of the current NIH Guidelines and to establish an equivalency or foreign assurance pathway, under which institutions may certify compliance with their national biosafety law while committing to the Policy's core principles, including risk assessment before work begins, proportionate biosafety oversight using a tiered review approach, and appropriate containment and approval requirements.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): The University of Sydney welcomes the Policy's intention to serve as a model framework. However, a mandatory institution-wide requirement may discourage voluntary uptake and make international collaborations harder to sustain. Voluntary adoption is more likely if NIH offers a path that accommodates existing national regimes. We suggest:

- A verification of alignment with the Policy's principles, available to institutions that already operate under an accredited national biosafety regime, in place of full Assurance;

- A published self-assessment tool and mapping to international standards (the WHO Laboratory Biosafety Manual, 4th edition, and ISO 35001), so institutions can show equivalence;

- Open access to implementation of resources, training materials and templates for institutions not subject to the Policy, adaptable to local law.

The University value the partnership with the NIH and welcome the opportunity to engage further with NIH's Office of Science Policy as the Biosafety Policy is developed.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: While the University supports transparency and prompt incident reporting, we have concerns about the requirements for an Australian institution.

Application beyond NIH-funded research is unclear: Section II extends the Policy to non-NIH-funded research at any institution that receives NIH funding, but the posting and reporting requirements do not

say whether they follow. It is unclear whether minutes and incident reports covering non-NIH-funded work must be posted or notified to NIH, or whether the requirements apply only to NIH-supported research.

Duplication of established incident reporting systems: Institutions in Australia already operate established systems for reporting, investigating and responding to workplace incidents as obligated under Australia's legislation and regulations. Notifiable incidents affecting worker's health and safety are notified to the regulator SafeWork NSW, which can investigate and require corrective action. Incidents involving genetically modified organisms are reported to the Office of the Gene Technology Regulator, and notifiable infections to State health authorities where applicable. An additional overseas obligation to notify NIH within 24 hours of defined significant incidents (including laboratory-acquired infections, potential community releases, BSL-3/4 incidents and compliance violations) would duplicate this chain of reporting, investigation and response, without adding protection to the workers or the community.

Conflicting with other Australian regulations on disclosure: A blanket requirement to publish minutes and incident reports may conflict with existing Australian regulation on security, privacy and commercial confidentiality. For example, work with security sensitive biological agents under Australia's SSBA Scheme is controlled not only at the materials handling but also the information and systems that support it, with vetting required for personnel who have access. Publishing minutes or incident reports that describe agent inventories, facility details, or security gaps would conflict directly with the regulatory requirement. Incident reports involving exposures or infections may also contain health information about identifiable workers, the disclosure of which is restricted under Commonwealth and NSW privacy and health records legislation. While the Draft allows "appropriate and allowable redactions," it does not define what redactions are permitted or whether obligations under foreign laws may override these requirements.

Recommendation: We ask NIH to:

1) Limit mandatory reporting to NIH-supported research and the facilities where it is conducted, rather than all research at any institution with any NIH funding. To support transparency while avoiding local legal and regulatory conflict, there should be a public summary section in the incident and minutes templates, separate from a confidential record, for organisations to fulfill NIH obligation.

2) Specify which redactions are allowed from public posting, and confirm that security, privacy and commercial-confidentiality obligations under Australian law qualify and may override disclosure requirements;

3) Accept a single incident investigation report that satisfies both NIH and the Australian regulators, and tier reporting by severity so that administrative lapses are not on the same 24-hour clock as potential laboratory-acquired infections.

6. Other feedback relevant to this resource: The Draft would apply to all existing awards six months after the final Policy is published, and no covered research may be conducted until NIH has approved an institution's Assurance. This is too short for institutions to establish or adapt committees, agree arrangements with affiliates and obtain approval. The Draft also does not say how institutions outside

the United States obtain an Assurance, or how externally administered or shared IBCs and multi-institution projects are handled. In addition, the Policy adds requirements for biosafety officers, committee administration, training and public posting, while foreign recipients operate under constrained indirect-cost arrangements.

Recommendation: We ask NIH to extend the transition period to 18 - 24 months, with existing IBC approvals continuing until their scheduled renewal; to publish the Assurance process and timelines for foreign recipients, including single-review arrangements for shared IBCs; and to confirm that these compliance costs are allowable on awards to foreign recipients, or acknowledge the unfunded burden.

Description: Submission from The University of Sydney

THE UNIVERSITY OF SYDNEY

SUBMISSION TO THE NATIONAL INSTITUTES OF HEALTH - U.S. DEPARTMENT OF HEALTH & HUMAN SERVICES

FEEDBACK TO DRAFT NIH BIOSAFETY POLICY (NOTICE NUMBER: NOT-OD-26-112)

Prepared by: Biosafety – WHS Specialist

EXECUTIVE SUMMARY

The University of Sydney supports NIH's aim of risk-proportionate, transparent and accountable biosafety oversight, and welcomes the opportunity to comment on the Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112). As an Australian institution with researchers who receive NIH funding, and which already operates under national biosafety legislation and institutional policies and procedures, our comments focus on how the Policy would apply outside the United States. We ask NIH to:

1. **Narrow the reach.** Limit mandatory coverage to NIH-supported research and the facilities where it is conducted, rather than all research at any institution with any NIH funding and define what it means for research to be “sponsored by” or conducted “at the institution”.
2. **Recognise Australian regulation and legislation.** Retain the host-country deference in the current NIH Guidelines (Section I-C-1-b(3)) and provide an equivalency (foreign assurance) pathway for institutions already regulated under Australian biosafety and biosecurity law.
3. **Reconcile public posting and incident reporting with local law.** Security, privacy, and commercial-confidentiality obligations must be able to override disclosure requirements. NIH should also accept a single incident report that satisfies both NIH and the Australian regulators.
4. **Allow time and resources to transition.** Extend the transition period to 18–24 months, publish the Assurance process for foreign recipients, and confirm that compliance costs are allowable.
5. **Enable voluntary adoption.** Offer pathways and open access to resources for institutions that are not subject to the Policy.

BACKGROUND

NIH released the Draft NIH Biosafety Policy for public comment on 19 August 2026, with responses due by 19 October 2026. The Policy raises concerns about its scope, unintended consequences and practical implementation for institutions outside the United States. The following sections set out these concerns, each with a recommendation that would give NIH assurance of compliance with its biosafety oversight principles while maintaining collaborative research across jurisdictions.

SCOPE AND REACH OF THE POLICY

Section II applies the Policy to non-NIH-funded research at any institution receiving any NIH funding, and the Compliance and Enforcement provisions require institutions, as a term and condition of NIH funding, to ensure that all research conducted at or sponsored by them complies, whatever the funder. This is a significant change for institutions outside the United States. Under the current NIH Guidelines, the institution-wide requirement applies to research within the U.S. and its territories (Section I-C-1-a), while research performed abroad is covered only where it is supported by NIH funds or involves human testing of NIH-developed materials (Section I-C-1-b), and must comply with host-country rules where they exist (Section I-C-1-b-(3)).The University recognises that the Policy provides a sound framework of fundamental biosafety principles and practices for biomedical research, particularly as a model for institutions outside existing regulatory frameworks. However, it is not clear whether the Policy applies to foreign institutions that collaborate with a U.S. institution receiving NIH funding, or that receive NIH funding and conduct the research outside the U.S. The Draft also does not define “sponsored by” or “at the institution” or say whether an institution that receives NIH funds only as a subaward “receives any NIH funding”. As currently drafted, the Policy would cover an institution’s entire research portfolio, not just the NIH-funded work.

For a large Australian university such as ours, this means a single NIH award could bring work funded by our National Health and Medical Research Council, the Australian Research Council, the Medical Research Future Fund and industry under NIH terms. It could also reach facilities shared with affiliated hospitals and research institutes that the university cannot contractually bind.

Recommendation: We ask NIH to limit mandatory scope to only NIH-supported projects and the laboratories where they are conducted, to define "sponsored by" and "at the institution" (including affiliates, adjuncts and shared facilities), to clarify whether subaward-only funding brings an institution within scope, and to leave wider adoption to the voluntary provisions.

RECOGNITION OF AUSTRALIAN REGULATION ON HANDLING OF BIOHAZARDS

The University supports the Policy’s principle of tiered oversight calibrated to risk. The main gap for an Australian institution is that the Policy does not recognise foreign regulatory systems. The import, export, use, storage and transport of biological materials in Australia are already governed by Federal and State legislation, regulatory schemes, and technical standards. These protect Australian public health and safety, prevent the introduction and spread of infectious diseases and pests, safeguard the environment and give effect to Australia’s international treaty obligations. Non-compliance carries serious consequences including suspension of research, loss of licences and permits, and criminal penalties. Most of the Policy’s scope therefore already has a regulated counterpart in Australia, as the table below shows. Requiring foreign institutions to meet both systems would duplicate processes for the same work without improving safety and runs against the Draft’s stated aim of reducing red tape.

Biological Handling	Legislations/Standards	Biosafety Consideration	Regulator
General exposure to biological hazards at work	Work Health and Safety Act 2011 (NSW) & Work Health and Safety Regulation 2025 (NSW)	Employer's due diligence in minimising worker's exposure to the biological hazards at work	SafeWork NSW [State]
Work involved genetic manipulation or usage of genetically modified organisms (GMOs)	Gene Technology Act 2000 Gene Technology Regulations 2001	Management of unintentional release of biological materials posed by gene technology and genetically modified organisms through regulatory framework of organisation accreditation, facility certification, dealings classification, licensing, monitoring, inspection and reporting. Accredited organisations operate statutory Institutional Biosafety Committees established under the Regulator's guidelines, which assess and supervise dealings.	Office of the Gene Technology Regulator (OGTR), Department of Health [Federal]
Materials listed on Security Sensitive Biological Agents (SSBA) Regulatory Scheme	National Health Security Act 2007 (Cth), Part 3 National Health Security Regulations 2018 (Cth) SSBA Standards	The Scheme aims to designate biological agents that are of security concern to Australia and enforce a regulatory framework that limit opportunities for act of bioterrorism whilst maintain access to SSBAs for those with a legitimate need within secure laboratories.	Australian Centre for Disease Control [Federal]
Import permits for biological materials and subsequent control of materials of biosecurity concern under an Approved Arrangement	Biosecurity Act 2015 (Cth)	Imported biological material is regulated under a permit regime whereby materials are risk assessed for potential impact on the environment and economy. If a risk is found substantial, the material must enter an Approved Arrangement that allow handling under strict conditions of containment protocols, treatments, verification methods, documentation and record keeping. The organisation that handling Approved Arrangement materials is subject to regular, fee-for-service monitoring audits every 6 months.	Department of Agriculture, Fisheries and Forestry [Federal]
Biological materials on Dual-use of Defence &	Defence Trade Controls Act 2012	The Scheme runs on a permit regime under which the supply and brokering of listed human and animal	Defence Export Control, a

Strategic Goods List (DSGL)		pathogens and toxins, including intangible transfers to overseas collaborators is subject to strict conditions and approval by the Regulator. The listing overlaps substantially with the SSBA List and with Risk Group 3 and above organisms.	Commonwealth Regulator [Federal]
Reporting of notifiable infections	Public Health Act 2010 (NSW) and Regulation	Notification obligations relating to scheduled medical conditions, and NSW Health requirements engaging the University where clinical or diagnostic material is handled in shared precinct facilities.	NSW Health [State]
Transport of infectious substances	Australian Dangerous Goods Code and IATA Dangerous Goods Regulations	Classification, packaging, marking, documentation and consignor training for Category A and Category B infectious substances, including all inbound and outbound transfers of high-risk material.	Referenced by all the above regulators
Micro-organisms Risk Group classification and Physical Containment Level classification and requirement (equivalent to BSL 1-4)	AS/NZS 2243.3:2022 *Safety in laboratories, Part 3: Microbiological safety and containment*	The Standard is widely referenced by Australian regulatory instruments and regulators for the risk classification and containment requirements for handling microorganisms, and becomes binding where incorporated into legislation, licence conditions, facility certification or permit conditions.	Referenced by several of the above regulators

The current NIH Guidelines already recognises this. Section I-C-1-b(3) provides that, for NIH-supported research performed abroad, if the host country has established rules for the conduct of recombinant or synthetic nucleic acid research, the research must comply with those rules; only where the host country has no such rules must the research be reviewed by an NIH-approved Institutional Biosafety Committee or equivalent body and accepted by the host country's national authority. The Draft Policy contains no equivalent provision. Australia's Gene Technology Act 2000 already requires accredited organisations to operate Institutional Biosafety Committee under the Regulator's guidelines, so the oversight structure NIH seeks already exists in Australian law.

As currently drafted, research that falls under the "purview of another federal agency" may proceed under that agency's oversight, but this appears limited to U.S. agencies. We ask NIH to extend this recognition to foreign institutions operating within mature, nationally regulatory frameworks, such as Australia's, where equivalent oversight mechanisms already exist.

Recommendation: We ask NIH to retain the host-country deference in Section I-C-1-b(3) of the current NIH Guidelines and to establish an equivalency or foreign assurance pathway, under which institutions may certify compliance with their national biosafety law while committing to the Policy's core principles, including risk assessment before work begins, proportionate biosafety oversight using a tiered review approach, and appropriate containment and approval requirements.

PUBLIC POSTING AND INCIDENT REPORTING OBLIGATIONS

While the University supports transparency and prompt incident reporting, we have concerns about the requirements for an Australian institution.

- Application beyond NIH-funded research is unclear: Section II extends the Policy to non-NIH-funded research at any institution that receives NIH funding, but the posting and reporting requirements do not say whether they follow. It is unclear whether minutes and incident reports covering non-NIH-funded work must be posted or notified to NIH, or whether the requirements apply only to NIH-supported research.
- Duplication of established incident reporting systems: Institutions in Australia already operate established systems for reporting, investigating and responding to workplace incidents as obligated under Australia's legislation and regulations. Notifiable incidents affecting worker's health and safety are notified to the regulator SafeWork NSW, which can investigate and require corrective action. Incidents involving genetically modified organisms are reported to the Office of the Gene Technology Regulator, and notifiable infections to State health authorities where applicable. An additional overseas obligation to notify NIH within 24 hours of defined significant incidents (including laboratory-acquired infections, potential community releases, BSL-3/4 incidents and compliance violations) would duplicate this chain of reporting, investigation and response, without adding protection to the workers or the community.
- Conflicting with other Australian regulations on disclosure: A blanket requirement to publish minutes and incident reports may conflict with existing Australian regulation on security, privacy and commercial confidentiality. For example, work with security sensitive biological agents under Australia's SSBA Scheme is controlled not only at the materials handling but also the information and systems that support it, with vetting required for personnel who have access. Publishing minutes or incident reports that describe agent inventories, facility details, or security gaps would conflict directly with the regulatory requirement. Incident reports involving exposures or infections may also contain health information about identifiable workers, the disclosure of which is restricted under Commonwealth and NSW privacy and health records legislation. While the Draft allows "appropriate and allowable redactions," it does not define what redactions are permitted or whether obligations under foreign laws may override these requirements.

Recommendation: We ask NIH to:

i) Limit mandatory reporting to NIH-supported research and the facilities where it is conducted, rather than all research at any institution with any NIH funding. To support transparency while avoiding local legal and regulatory conflict, there should be a public summary section in the incident and minutes templates, separate from a confidential record, for organisations to fulfill NIH obligation.

ii) Specify which redactions are allowed from public posting, and confirm that security, privacy and commercial-confidentiality obligations under Australian law qualify and may override disclosure requirements;
iii) Accept a single incident investigation report that satisfies both NIH and the Australian regulators, and tier reporting by severity so that administrative lapses are not on the same 24-hour clock as potential laboratory-acquired infections.

TRANSITION, ASSURANCE PROCESS AND COST

The Draft would apply to all existing awards six months after the final Policy is published, and no covered research may be conducted until NIH has approved an institution's Assurance. This is too short for institutions to establish or adapt committees, agree arrangements with affiliates and obtain approval. The Draft also does not say how institutions outside the United States obtain an Assurance, or how externally administered or shared IBCs and multi-institution projects are handled. In addition, the Policy adds requirements for biosafety officers, committee administration, training and public posting, while foreign recipients operate under constrained indirect-cost arrangements.

Recommendation: We ask NIH to extend the transition period to 18 - 24 months, with existing IBC approvals continuing until their scheduled renewal; to publish the Assurance process and timelines for foreign recipients, including single-review arrangements for shared IBCs; and to confirm that these compliance costs are allowable on awards to foreign recipients, or acknowledge the unfunded burden.

ENABLING VOLUNTARY ADOPTION

The University of Sydney welcomes the Policy's intention to serve as a model framework. However, a mandatory institution-wide requirement may discourage voluntary uptake and make international collaborations harder to sustain. Voluntary adoption is more likely if NIH offers a path that accommodates existing national regimes. We suggest:

- A verification of alignment with the Policy's principles, available to institutions that already operate under an accredited national biosafety regime, in place of full Assurance;
- A published self-assessment tool and mapping to international standards (the WHO Laboratory Biosafety Manual, 4th edition, and ISO 35001), so institutions can show equivalence;
- Open access to implementation of resources, training materials and templates for institutions not subject to the Policy, adaptable to local law.

The University value the partnership with the NIH and welcome the opportunity to engage further with NIH's Office of Science Policy as the Biosafety Policy is developed.

I am responding: On behalf of myself

Name: Kari Seedle

Name of Organization: University of Hawaii

Type of Organization: Academic Institution

Role: Other

Role - Other: IBC Coordinator

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Educational research

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: I agree with the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA), but would like to add:

Clarification of Key Definitions: Clearly define foundational terms (e.g. biological agent, toxin, genetic modification, laboratory research, genetically modified organism (GDMO) within the policy to ensure consistent interpretation and compliance across institutions.

Clarify Acronyms: Before adding an acronym, spell it out first.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): I agree with the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA), but would like to add:

There is a typo under IBC Functions in the first bullet: Reviewing research for compliance with the Policy as specified in Section IV" Categories of Oversight for Research Based on Risk" and approving, as warranted, research that meets the requirements of the Policy.
If keeping this sentence, fix to: Reviewing research for compliance with the Policy as specified in Section IV "Categories of Oversight for Research Based on Risk" and approving, as warranted, research that meets the requirements of the Policy.

3. Continued utility of Risk Groups: I agree with the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA), but would like to add:

Implementation Resources & National Risk Database: Develop comprehensive guidance tools, including a national database for Risk Group and containment determinations, to foster consistent, evidence-based risk assessments.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): I agree with the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA), but would like to add:

Recalibration of Public Posting: Adjust public disclosure requirements to balance public transparency with institutional security and administrative feasibility. Public posting of incidents as drafted is likely to discourage prompt reporting. If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. Remove wording that IBC rosters must be publicly-posted.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: I agree with the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA), but would like to add:

24-Month Phased Transition Period: Provide a minimum 24-month phased transition period to enable institutions to update procedures, retrain staff, and adapt administrative systems smoothly. Where appropriate, permit conversion at a significant amendment or schedule d renewal, with safeguards and priority for higher-risk work. Preserving staggered renewal cycles will help to avoid unnecessary backlogs.

SUBJECT: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Support for CSHEMA Recommendations

To Whom It May Concern:
I am writing to express support for the National Institutes of Health's (NIH) efforts to modernize biosafety oversight and establish a comprehensive, risk-based framework. I appreciate the opportunity to offer feedback on the draft policy.

As an IBC Coordinator my work would be directly impacted by the proposed NIH biosafety policy. I endorse the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA). CSHEMA'S recommendations appropriately reflects the practical needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

While I support CSHEMA's comments in full, I would like to draw particular attention to several priority areas that are vital to our institution's operations:

- **Clarification of Key Definitions:** Clearly define foundational terms (e.g. biological agent, toxin, genetic modification, laboratory research, genetically modified organism (GDMO) within the policy to ensure consistent interpretation and compliance across institutions.

- **Recalibration of Public Posting:** Adjust public disclosure requirements to balance public transparency with institutional security and administrative feasibility. Public posting of incidents as drafted is likely to discourage prompt reporting. If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. Remove wording that IBC rosters must be publicly-posted.

- **Implementation Resources & National Risk Database:** Develop comprehensive guidance tools, including a national database for Risk Group and containment determinations, to foster consistent, evidence-based risk assessments.

- **24-Month Phased Transition Period:** Provide a minimum 24-month phased transition period to enable institutions to update procedures, retrain staff, and adapt administrative systems smoothly. Where appropriate, permit conversion at a significant amendment or schedule d renewal, with safeguards and priority for higher-risk work. Preserving staggered renewal cycles will help to avoid unnecessary backlogs.

Thank you for your consideration of these comments and for your commitment to advancing biosafety oversight.

Sincerely,

Kari Seedle
Biosafety Program Specialist
IBC Coordinator

Description: WSU Comments on NIH Biosafety Policy for Research Involving Biohazards

WASHINGTON STATE UNIVERSITY

Office of Research Assurances

ELECTRONIC DELIVERY

October 19, 2026

Dear National Institute of Health, Office of Science Policy,

On behalf of Washington State University (WSU), we appreciate the opportunity to provide comments on the proposed Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112). As a public land-grant research university with a broad portfolio spanning biomedical, agricultural, environmental, and life sciences research, WSU has a strong interest in ensuring that biosafety policies effectively support both scientific advancement and responsible oversight.

WSU recognizes NIH's efforts to modernize and consolidate biosafety requirements through the development of a new policy framework intended to replace the NIH Guidelines for Research Involving Recombinant or Synthetic Nucleic Acid Molecules. We support the goals of maintaining robust biosafety practices, promoting public trust in the research enterprise, and providing institutions with clear expectations for the oversight of research involving biological hazards.

Because the proposed policy would establish new requirements affecting institutional governance, investigator responsibilities, reporting practices, and biosafety review processes, it will have substantial implications for the administration of research programs across the academic community and for the researchers themselves. WSU has reviewed the proposal with particular attention to provisions that may affect the effectiveness of biosafety oversight, consistency of implementation, and the administrative resources required to achieve compliance, as well as the impact on the Principal Investigator and research teams.

WSU supports the biosafety community comments included within R. Moritz et. al. document titled “A White Paper on Finalizing and Implementing the Proposed NIH Biosafety Policy.” The comments below are in addition to this document and identify areas where additional clarification or modification would improve the policy's effectiveness while continuing to support NIH's objectives of protecting researchers, the public, and the environment.

Section II

Scope: The draft policy extends oversight beyond recombinant or synthetic nucleic acid research to include wild-type biological agents that cause human disease but omits pathogens that affect only animals or plants. The addition of wild-type organisms previously outside the scope of the NIH guidelines may add significant burden to institution’s IBC review volume. WSU recommends the NIH to identify frameworks for non-zoonotic animal-pathogen oversight.

Plants: As a land-grant institution with a significant agricultural research portfolio, WSU conducts and oversees numerous projects involving genetically modified plants. WSU is

concerned that excluding genetically modified plants from the scope of the proposed policy may create gaps in biosafety oversight and risk management.

Although current research involving genetically modified plants or modified microorganisms associated with plants is conducted under established containment and stewardship practices, potential loss of containment remains a concern. Such events could result in environmental impacts, economic consequences, and reputational harm to research institutions and the broader research enterprise. WSU believes that including genetically modified plants within the policy would promote a more comprehensive and consistent approach to biosafety oversight across federally funded research activities.

For consistency, WSU therefore recommends that the IBC Membership section include the requirement of a plant expert on the IBC when institutions conduct plant research that falls within the policy's scope. Furthermore, in the Laboratory Research section, WSU recommends explicitly incorporating Plant Biosafety Levels within the definition of laboratory research. Doing so would help ensure that plant research activities are appropriately addressed within the policy framework and that containment standards are applied consistently across research systems. Finally, in Section IV-2 Research That Requires IBC Review and Approval Before Initiation, WSU recommends removing the language that exempts genetically modified plants and plant cells.

Toxin: WSU seeks clarification as to the proposed definition of toxin as protein-based, as it may be interpreted too narrowly. The definition does not expressly account for biologically derived, non-proteinaceous toxins that may pose significant risks to human and animal health. Examples include, but are not limited to, saxitoxin, lipopolysaccharide (LPS), and tetrodotoxin. These substances can present substantial hazards despite not being protein-based and should be considered within the policy's risk management framework.

Section III-A/B/C

Incident Reporting: WSU is concerned that requiring incident reports to be posted on publicly accessible websites using the proposed template creates unintended risks to Principal Investigator and researcher safety and privacy. The goals associated with this transparency are most effectively obtained when the information disclosed enhances public understanding, accountability, and confidence in the oversight process. The requirement of routine publication of investigator names, grant numbers, internal project numbers, sensitive animal information, select agent information, proprietary research details, identifying facility information, or other details likely compromises safety, security, or personnel protection. Furthermore, public disclosure requirements of this nature may have a chilling effect on incident reporting. Institutions and investigators may be less willing to report incidents promptly and comprehensively if doing so results in broad public dissemination of investigator-specific information.

Minutes: Similarly, WSU is concerned that requiring institutions to use the proposed meeting minutes template as written would substantially increase administrative burden for IBC staff while providing information that is largely duplicative of existing IBC review and documentation practices. Furthermore, certain requirements may create unnecessary risks to Principal Investigator privacy and safety. Specifically, the proposed template requires inclusion of PI names, Project Overview, Risk Assessment and Discussion, and Occupational Health Representative Review. These elements are largely redundant within

meeting minutes, as a comprehensive risk assessment already incorporates project-specific information, including an overview of the research and relevant occupational health considerations. Requiring these topics to be documented separately in meeting minutes would duplicate information already reviewed and maintained as part of the protocol review process without providing significant additional value. Furthermore, the proposed policy requires research protocols to include risk assessments, and those protocols may be subject to disclosure through public records processes. If the intent is to enhance transparency and public trust, WSU notes that existing IBC composition requirements already address this objective by requiring community representatives who are responsible for representing the interests of the surrounding community with respect to public health and environmental protection. WSU recommends template flexibility, including the following sections as optional rather than mandatory elements: Project Overview, Risk Assessment and Discussion, and Occupational Health Representative Review.

WSU recommends further clarification on allowable redactions, namely deidentification of people and details that compromise safety and security, for both publicly posted Incident Reports and Minutes.

Record Retention: WSU notes that the proposed policy requires institutions to maintain all IBC records for three years following submission of the final financial report, consistent with 2 CFR 200.334. However, the proposal also requires that IBC meeting minutes be retained for a minimum of five years to comply with NIH Grants Policy Statement requirements. Clarification between these standards would ensure greater compliance.

Initial submission, Periodic, and *de novo* protocol review: The proposed requirement for research protocols to undergo *de novo* review every three years in addition to periodic reviews is unclear. Under current practices, IBC protocols are generally maintained as living documents that are continuously updated as research activities evolve. Protocols are typically subject to periodic renewal and ongoing review, allowing committees to evaluate significant modifications, changes in risk, and continuing compliance throughout the life of a project. This approach provides sustained oversight while avoiding unnecessary duplication of effort. Implementation guidance for currently approved protocols and whether they would need to be reviewed again or be grandfathered until renewal is also needed.

Biological Safety Officer (BSO): WSU recognizes the important role that the Biological Safety Officer plays in supporting institutional biosafety programs and ensuring compliance with biosafety requirements. However, WSU is concerned that the proposed responsibilities outlined in this section appear to assume that all BSO functions must be performed by a single individual. At many institutions, effective biosafety oversight is achieved through a team-based approach in which responsibilities are appropriately shared among associate BSOs, biosafety professionals, and other qualified personnel. Delegation helps ensure continuity of operations, promotes timely completion of required activities, and reflects the organizational structures commonly used to support modern research programs. Additionally, the provision that institutions that do not designate a BSO must assign another official to fulfill BSO responsibilities lacks clarity. Without clearly defined minimum qualifications, institutions may face uncertainty regarding compliance expectations and the level of expertise necessary to adequately perform these responsibilities. Accordingly, WSU recommends adding language that explicitly permits the delegation of appropriate responsibilities to qualified designees under the oversight of a designated BSO. WSU further

recommends establishing minimum qualifications and competency expectations for any alternate official designated to perform BSO responsibilities when a BSO has not been appointed.

Principal Investigator (PI): WSU requests clarification regarding the final paragraph of this section, which encourages the submission of reports concerning near-misses, secondary containment failures, and procedural issues to the National Biosafety Data and Safety Analysis Center (NBDSAC). As written, it is unclear whether the policy intends Principal Investigators to submit such reports directly, or whether the recommendation is directed toward institutions through their Institutional Biosafety Committees (IBCs) or other institutional oversight mechanisms. The paragraph references “institutions,” but its placement within the section describing PI responsibilities creates ambiguity regarding who is responsible for reporting and under what circumstances. Clarification of what information should be submitted to NBDSAC, how these should be redacted or de-identified, who may access this identifiable information, and whether and how records may be disclosed. It should also be clarified that this voluntary reporting remains separate from mandatory compliance reporting.

Section IV
Research That Requires Review and Approval Before Initiation and May Be Delegated to an Individual or Subgroup of IBC Members: Clarification of research criteria permissible under a designated review model versus full committee would ensure compliance with the policy. Without clearly defined criteria, institutions may apply differing risk thresholds when determining whether research qualifies for delegated review. This variability could create uncertainty for investigators and oversight committees and may result in inconsistent levels of review for research activities with similar risk profiles. WSU is concerned that the terms “low-risk transgenes” and “well-characterized cell lines” are not clearly defined within the proposed policy. Because these categories may be used to determine eligibility for delegated review, ambiguity in their definitions could result in inconsistent interpretation and implementation across institutions. Additionally, a definition of “clinical research” is needed to ensure all activities have proper oversight. WSU recommends that the policy provide clear, objective, and risk-based definitions for “low-risk transgenes.” For example, the policy could specify characteristics that would exclude a transgene from this category, such as transgenes encoding oncogenic factors, clinically relevant antibiotic resistance determinants, toxins, or other products that could reasonably increase risks to human health, animals, plants, or the environment. Similarly, WSU recommends that the policy define what constitutes a “well-characterized cell line,” including the minimum information or documentation necessary to establish a cell line's origin, properties, history of use, and associated risk profile. Clear criteria would help ensure consistent application of delegated review processes across institutions and provide greater transparency for investigators and oversight committees.

Conclusion
WSU supports NIH's commitment to maintaining a strong and effective framework for biosafety oversight and appreciates the effort invested in developing a modernized policy for research involving biohazards. The proposed policy presents an important opportunity to strengthen institutional biosafety programs while promoting consistency, transparency, and public confidence in federally supported research. WSU believes that well-defined requirements and appropriately tailored oversight mechanisms will enhance institutional

compliance and allow biosafety resources to remain focused on activities that present the greatest risks.

We appreciate NIH's willingness to engage with the research community during this process and welcome continued dialogue on the development of a practical, effective, and science-based biosafety framework. Thank you for the opportunity to provide comments on the proposed policy.

Sincerely,
Washington State University

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: Policy Comments:

The definition of a "biological agent" as any bacteria, viruses, fungi or parasites that specifically causes human disease does not align with current scientific terminology in use. This term and definition has the potential to cause extensive confusion when compliance/safety personnel communicate with the broader scientific community and should be revised.

Mandatory de novo review required specifically at three years would substantially increase workload for many investigators, BSOs, IBC staff, committee members, and institutional officials. Permit IBC approvals for up to five years which has been commonly utilized in this field. Authorize temporary administrative extensions for currently approved work when a subsequent a de novo institutional review is in progress.

Permit delegated review when primary cells may contain an RG2 agent, consistent with the delegated-review pathway for work conducted directly with wild-type RG2 biological agents.

Define what information must be included for a delegated approval to be “reported in full.” Permit institutions to report each delegated approval using information such as institutional registration number, general research category, type of submission or amendment, broad biological materials, containment level, approval date, and material conditions with opportunity for committee discussion and request for full review.

NIH should also establish a process for publishing and reusing its RG determinations. The draft requires NIH to publish approved lower-containment determinations for RG3 and RG4 agents, but it is less explicit about publishing all determinations for emerging, novel, or zoonotic agents. NIH should maintain a searchable repository that institutions may rely upon when proposed work involves the same agent or a materially equivalent agent, construct, attenuation, and experimental procedure.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Comments on Incident Reporting :

Limit reporting of facility or equipment failures to failures that compromise containment and/or create a risk to personnel, the public, or the environment. The current language is overly broad. Clarify that failure of any single component of facility or equipment does not constitute a reportable event when redundant containment systems or strategies function as intended and no release or potential exposure occurs. A failure of a component or equipment does not necessarily result in a loss of containment or potential exposure, particularly when redundant systems and strategies function as designed by the institution. This is the purpose of these risk mitigation systems and strategies and is a reflection that they functioned correctly. Notification and reporting should focus on failures that compromise containment and/or create a risk to personnel, the public, or the environment.

Remove the requirement for institutions to publicly post PI name and specific grant identifiers for incidents. Effective biosafety programs depend on prompt reporting, candid investigation, and meaningful analysis of contributing factors. Public disclosure of overly detailed project specific identifiers such as those mentioned may permit public identification of affected individuals (especially for small research groups) even when specific personnel identifiers are removed and may discourage personnel from reporting due to negative consequences of public identification.

Limit federally reportable compliance violations to substantive violations that materially compromise biosafety oversight or result in covered research being conducted without required approval or containment. Permit institutions to document and correct minor administrative discrepancies without immediate federal notification when the discrepancy does not affect safety or oversight.

Start the 24-hour notification period when the BSO, IBC Chair, IBC office, institutional official, or another designated institutional authority has sufficient information to reasonably determine that the event meets NIH reporting criteria and require the initial notification to include only information reasonably available at the time of reporting.

I am responding: On behalf of myself

Name: Nancy Connell

Name of Organization: Rutgers University (Rutgers NewJersey Medical School)

Type of Organization: Academic Institution

Role: Institutional Review Oversight Committee Member

Date Submitted: 10/19/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): infectious disease research (pathogenesis, drug discovery, medical countermeasures); science policy; biosafety and biosecurity

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The proposed scope is limited by its focus on known or potential risk to human health. Plants, animals and their relationship to the environment -and to humans - are not addressed. How will NIH coordinate with other agencies? Will the gaps in oversight be filled? Furthermore, what exactly is meant by "known or potential risk to human health"? Is the institution responsible for evaluating and positioning research with respect to the "threshold" vs the enumerated biohazard categories? In other words, it is not clear whether "relatively low-risk research, including genetically modiied RG1 biological agents, BSL-1/ABSL-1 transgenic organisms,
well-characterized cell lines, and certain plasmids and low-risk transgenes" must also be determined to pose risk to human health, or whether just including some of these biohazards means the research is covered. If the latter is the case, there will be huge increase in oversight infrastructure and many universities and colleges will be unable to accommodate this kind of work. This would be a real loss to the scientific enterprise as a whole, as labs begin to shut down one by one.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: Risk Groups should not serve as a classification that drives laboratory oversight for the following reasons:
• The RGs describe risk to healthy adults in the community and are purported to reflect the potential effect on a healthy human adult. In a laboratory, no one can verify that a oworker is healthy, and some individuals are more susceptible because of
medications, immune status, or pregnancy.
• They reflect community exposure, not laboratory conditions. Laboratory concentrations, volumes, and manipulations differ greatly from what occurs in the
community or environment.
• They have no baseline for novel constructs. Recombinant and synthetic nucleic acid work and synthetic cells do not exist in the community until they have been studied in the laboratory,
• They cover only human etiologic agents. The Policy’s definition of biohazards is broader than agents

that cause human disease, so RGs cannot be the basis for classifying biohazardous material.
• They are misinterpreted. Researchers and Federal agencies treat the RG number as a containment requirement. This becomes a potential safety issue for laboratory
personnel and for the environment outside the laboratory.
In fact, the policy appears to conflate RG with biosafety level.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: There is no clear biosafety or public safety rationale provided to clarify the public interest or biosafety rationale for requiring PI identification in individual incident reports. NIH should consider whether such identification is necessary when it does not materially contribute to understanding or
preventing these incidents.
Publication of IBC minutes could compromise the privacy scientists and other workers, and may also reveal over time important scientific intellectual property.

Description: Alliance for Vision Research Response to RFI

October 19, 2026

Jay Bhattacharya, MD, PhD
Director
Office of the Director
National Institutes of Health
1 Center Drive MSC 0122
Bethesda, MD 20892

RE: Comments on Draft NIH Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112)

Dear Director Bhattacharya:

On behalf of the Alliance for Vision Research, we appreciate the opportunity to submit comments on the National Institutes of Health (NIH) Draft Biosafety Policy for Research Involving Biohazards (NOT-OD-26-112).

The Alliance for Vision Research is a national nonprofit advocacy organization dedicated to advancing federal investment in vision research and championing policies that accelerate scientific discovery, foster innovation, and support the development and delivery of new treatments and cures for blinding eye diseases and vision disorders. We strongly support rigorous biosafety protections, responsible institutional oversight, transparency, and NIH's efforts to modernize a framework historically focused on recombinant and synthetic nucleic acid research. We also welcome NIH's stated objective of reducing unnecessary oversight for lower-risk research.

However, the Alliance is concerned that several provisions, unless further defined and refined, could subject routinely conducted, appropriately controlled research to requirements disproportionate to its actual biological risks. An effective policy should distinguish meaningful, reasonably anticipated hazards from theoretical possibilities; establish clear and consistent oversight pathways; and protect both safety and the continuity of valuable biomedical research.

These distinctions are especially consequential for vision research, which relies on a diverse range of human- and animal-derived approaches—including genetically modified mice and zebrafish, donor ocular tissues, primary retinal and anterior-segment cells, retinal organoids, and gene-delivery technologies. Their risks vary according to the source and characteristics of materials, experimental manipulation, potential routes of exposure, and containment measures. The use of a particular model or genetic modification should not, by itself, be treated as evidence of a significant human-health hazard.

Clarify Policy Scope and Apply Risk-Proportionate Oversight (Sections II and IV)

The draft's institutional applicability may extend to research conducted at NIH-supported institutions even when individual projects receive private or other non-NIH funding. NIH should clarify its application to privately sponsored studies, collaborations, shared facilities, and institutional storerooms, including how relevant state requirements and existing federal oversight intersect with the new policy. Institutions need clear guidance about which activities require full Institutional Biosafety Committee (IBC) review and which may be addressed through documented institutional assessment or delegated review.

NIH should provide practical examples for commonly used vision-science methods, including well-characterized, low-risk genetically modified animals, human-derived cells and tissues, and nonreplicating gene-delivery systems. These examples should establish a consistent, risk-based approach without imposing new review requirements solely because a model involves genetic modification or a particular biological source.

Define Adventitious Agents and Appropriate Thresholds for Primary Cells (Section IV-2)

The Alliance is particularly concerned about the proposed coverage of "primary cells that may be contaminated by adventitious agents." Without a definition of "adventitious agent" or a meaningful risk threshold, this language could be interpreted to encompass nearly any primary human or animal cell or tissue for which the absence of every conceivable agent has not been conclusively demonstrated. In vision research, that could include donor-derived retinal tissue, retinal pigment epithelial or corneal cells, patient-derived ocular specimens, and nonhuman primate cells and tissues.

Certain biological specimens warrant heightened precautions. Nevertheless, a purely hypothetical possibility of contamination should not automatically trigger full-committee review. NIH should distinguish known or reasonably anticipated hazards from remote or theoretical possibilities and explain how donor screening, testing, specimen provenance, supplier documentation, handling conditions, and plausible exposure pathways inform the assessment. Eye banks supplying donor ocular tissue for corneal transplantation already operate under applicable federal infectious-disease screening and testing requirements; relevant documentation and safeguards should be appropriately recognized rather than unnecessarily duplicated.

The final policy should specifically address commercially supplied primary cells, specimens held in institutional storerooms or repositories, patient-derived material, primary animal tissues, and nonhuman primate material, recognizing that risks differ by source and species. NIH should identify examples of materials that are included and excluded, allow appropriately documented low-risk activities to proceed through delegated review, and clarify how screening and source documentation contribute to a comprehensive biosafety assessment.

This clarification is particularly important as NIH encourages human-based research and New Approach Methodologies (NAMs). An expansive interpretation of the primary-cell provision could inadvertently discourage the use of organoids, tissue-based disease models, and other emerging methodologies, creating delays and administrative costs without a corresponding, demonstrated safety benefit.

Coordinate Oversight for Animal Models and Existing Institutional Requirements

Genetically modified mice and zebrafish remain important for investigating retinal development, inherited and age-related retinal degeneration, glaucoma, dry eye disease, optic nerve injury, and visual recovery. Where hazards are well characterized and containment is appropriate, streamlined review should be available. NIH should support coordinated documentation and clearly distinguish IBC responsibilities for biosafety from institutional animal-care and animal-welfare oversight to avoid unnecessary duplication or recurring approvals for low-risk activities.

The final policy should also distinguish routine husbandry incidents from events that present a meaningful biosafety concern. Aligning these processes would preserve protections while limiting delays to research conducted under established safeguards.

Support Human-Derived Models, Gene Delivery, and Translational Research

Human retinal organoids, induced pluripotent stem-cell-derived systems, gene-edited cell models, and viral and nonviral delivery tools are essential to understanding disease mechanisms and evaluating promising therapies. Oversight should reflect whether biological material is infectious or replication-competent, whether experimental manipulation meaningfully changes risk, and whether a plausible route of exposure exists—not simply the presence of gene editing or a delivery platform.

NIH should publish examples of appropriately characterized cell systems and delivery approaches eligible for streamlined or delegated review. Consistent expectations across institutions and approved international collaborations would be particularly valuable for multisite research and early-career investigators who are less equipped to absorb unpredictable administrative requirements.

Promote Transparency Without Compromising Research Security (Section III)

The Alliance supports public accountability and meaningful reporting of biosafety incidents. However, requirements to publicly post IBC minutes and incident reports should include clear, standardized safeguards for personnel privacy, unpublished findings, proprietary techniques, sensitive facility information, and research security. NIH should establish uniform redaction standards and permit public summaries where disclosure of detailed records would not meaningfully improve public understanding.

Similarly, reporting thresholds should differentiate serious or potentially consequential incidents from minor, contained events appropriately handled through routine institutional processes. Reporting requirements should encourage prompt internal disclosure, corrective action, and institutional learning, rather than create disincentives to report or permit routine laboratory occurrences to be mischaracterized as substantial safety failures.

Allow Realistic Implementation and Proportionate Compliance (Sections II–V)

The proposed six-month implementation period may be insufficient for institutions to revise policies, expand IBC capacity, train investigators and staff, and harmonize oversight across funding sources. NIH should evaluate administrative burden, staffing, operational costs, and institutional readiness, and provide model procedures, templates, training, and practical examples

before implementation. A longer, phased transition would better position institutions to implement the policy effectively and consistently.

NIH should also calibrate compliance actions to the nature and severity of a violation, the actual risk posed, and the adequacy of corrective action. Isolated, minor procedural lapses should not automatically jeopardize unrelated NIH-supported awards or disrupt laboratories, trainees, clinical research, and patients who depend on the continuity of vision research.

Finally, NIH should explicitly address whether the policy applies retroactively to collections of cells or tissues obtained before its effective date, particularly materials that have been used safely for years. NIH should specify any additional screening, documentation, or review obligations for existing collections and account for the risk of disrupting ongoing studies or rendering valuable research resources impractical to use.

Recommendations

To advance NIH's biosafety objectives while sustaining rigorous and innovative biomedical research, the Alliance for Vision Research respectfully recommends that NIH:

1. Define "adventitious agent" and establish clear thresholds tied to known or reasonably anticipated human-health risks for primary human and animal cells and tissues, with practical included-and-excluded examples.
2. Provide explicit delegated or streamlined pathways for appropriately characterized low-risk primary tissues, cell models, genetically modified animals, and gene-delivery systems.
3. Clarify the policy's reach across funding sources, shared institutional facilities, and collaborations, while recognizing applicable federal, state, and institutional oversight.
4. Coordinate IBC responsibilities with existing animal-care and other institutional review processes, avoiding duplicative documentation and ongoing approvals where risks are already well characterized.
5. Establish consistent standards for public disclosure, redaction, and incident reporting that protect research security and distinguish consequential biosafety events from minor or routine incidents.
6. Provide implementation tools, training, realistic burden and cost assessments, and a longer, phased transition that reflects institutional capacity and readiness.
7. Adopt risk-proportionate enforcement and meaningful opportunities for corrective action so minor violations do not unnecessarily interrupt unrelated ongoing NIH-funded research.
8. Clarify whether and how the policy applies to previously collected cells and tissues, including any retrospective documentation, testing, or review requirements, to protect continuity of established research.

The Alliance for Vision Research shares NIH's commitment to protecting research personnel and the public while maintaining confidence in the integrity of the biomedical research enterprise. These goals are fully compatible with clearly defined, scientifically grounded biosafety standards that apply oversight in proportion to actual risk. For patients and families affected by blinding eye diseases and vision disorders, avoidable delays in research can ultimately delay the discoveries and therapies they are waiting for.

We respectfully urge NIH to refine the proposed policy and accompanying guidance to ensure that strong biosafety protections do not unintentionally create unnecessary barriers to well-characterized animal- and human-based research, including the innovative methodologies NIH seeks to advance. By providing clearer definitions, consistent risk assessments, streamlined review where appropriate, and realistic implementation expectations, NIH can strengthen both laboratory safety and the nation's ability to advance vision research.

Thank you for the opportunity to provide comments on this important proposal. If you have questions or would like to discuss these recommendations, please contact me at 202-742-1885 or dan@eyeresearch.org. The Alliance for Vision Research welcomes continued engagement with NIH and the research community as the policy and implementing guidance are finalized.

Sincerely,

[redacted]

Dan Ignaszewski
Executive Director
Alliance for Vision Research

SUBJECT: Comment on NIH Effort to Modernize and Strengthen Biosafety Oversight – Support for CSHEMA Recommendations

To Whom It May Concern:
I am writing to express support for the National Institutes of Health's (NIH) efforts to modernize biosafety oversight and establish a comprehensive, risk-based framework. I appreciate the opportunity to offer feedback on the draft policy.

As a community member of the University of Hawaii IBC, my work with the IBC will be impacted by the proposed NIH biosafety policy. I endorse the comments submitted by the Campus Safety, Health, and Environmental Management Association (CSHEMA). CSHEMA'S recommendations appropriately reflects the practical needs and perspectives of higher education and research institutions working to maintain safe, compliant biosafety programs.

While I support CSHEMA's comments in full, I would like to draw particular attention to several priority areas that are vital to our institution's operations:

- **Clarification of Key Definitions:** Clearly define foundational terms (e.g. biological agent, toxin, genetic modification, laboratory research, genetically modified organism (GDMO) within the policy to ensure consistent interpretation and compliance across institutions.

- **Recalibration of Public Posting:** Adjust public disclosure requirements to balance public transparency with institutional security and administrative feasibility. Public posting of incidents as drafted is likely to discourage prompt reporting. If public posting is retained, NIH should allow redaction of PI names, grant identifiers, and other redactions necessary for the protection of proprietary and security-sensitive information. Remove wording that IBC rosters must be publicly-posted.

- **Implementation Resources & National Risk Database:** Develop comprehensive guidance tools, including a national database for Risk Group and containment determinations, to foster consistent, evidence-based risk assessments.

- **24-Month Phased Transition Period:** Provide a minimum 24-month phased transition period to enable institutions to update procedures, retrain staff, and adapt administrative systems smoothly. Where appropriate, permit conversion at a significant amendment or schedule d renewal, with safeguards and priority for higher-risk work. Preserving staggered renewal cycles will help to avoid unnecessary backlogs.

Thank you for your consideration of these comments and for your commitment to advancing biosafety oversight.

Sincerely,

Paul M. Fox, Ph.D.

530. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy should address genetically modified plants (specifically greenhouse work), plant-associated harmful organisms, genetically modified plant pathogens, animal only pathogens (non-zoonotic), and work with agricultural animal in a research setting. There should also be clarity on where the USDA or other federal agencies have oversight that satisfy NIH policy on biosafety and how the IBC should mange such overlap.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: N/A

531. N/A

I am responding: On behalf of myself

Name:

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: N/A

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): The expansion of the proposed policy to require NIH approval on emerging, novel, or zoonotic agents that lack a Risk Group classification or containment level according to the BMBL for material otherwise handled at BSL-1 or -2 will be a huge burden on local institutions and IBCs and extremely hard to manage or capture. Some of these agents come up during routine screenings or when using gene libraries to find an intended product but produce other side mutations that are unwanted and then discarded. The Policy should allow local IBCs with SMEs to make these risk assessments and determinations whether further NIH review is needed, such as when there is significant environmental consequences.

3. Continued utility of Risk Groups: Well characterized human cell lines are either captured under OSHAs BBP Standard or have been downgraded to safely handle at BSL-1 under set parameters. The policy could add such parameters, such as required testing for BBP and cell banking. Following vetted downgrade guidelines should not require additional IBC or NIH review. There is no additional risk assessment required for human cells beyond an initial assessment to identify source and potential contamination risk. Most modified human cells don't pose an additional risk beyond that. Requiring all well characterized human cell lines to be registered separately is a huge administrative burden that would more harm the biosafety program and provide any benefit.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Review by NIH of minor incidents that are then required to be publicly posted seems more punitive than helpful. Low-risk incidents and near misses should be managed thru the local IBC and biosafety program to encourage such reporting by researchers to the biosafety team, which then follows up, learns from, and instructs to avoid such incidents in the future. Requiring the publication of such incidents will cause lab staff to rather not report for fear of retribution.

6. Other feedback relevant to this resource: N/A

532. Marie-Luise Faber

I am responding: On behalf of myself

Name of Organization:

Type of Organization: Not Applicable

Role: Member of the Public

Date Submitted: 10/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): N/A

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: The policy does not address current work that has been approved by IBCs or biosafety programs at institutions. Will the policy only focus on research and new material being brought in after the final draft or will existing research also fall under the new policy. If that later is to be implemented, how will this be done. Will existing exemptions issues under the NIH Guidelines be kept in place? Will new risk determinations by the NIH apply to all institutions, as they have in the past, or will each institution or lab be required to apply for approval or exemption? The proposed policy reaches far beyond what most IBC register today. How will this existing material and research be folded into the new policy?

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): N/A

3. Continued utility of Risk Groups: N/A

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): N/A

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: N/A

6. Other feedback relevant to this resource: Federal funding is needed to support this policy if it is to be successful and robust. The NIH needs to pilot pieces of the new policy, such as meeting minutes, incident reporting systems, and delegated review tools, by working with large and small institutions, rural and urban, or resource rich and poor to see what works best and what customization is needed for varying institutions to achieve a uniform outcome. There will also be a need for additional training of biosafety professionals to adapt new requirements to current research. The NIH will need to assess the cost and impact of the new policy on al the entities listed above before requiring implementation.

533. La Trobe University

I am responding: On behalf of an organization

Name: Alistair Duncan

Name of Organization: La Trobe University

Type of Organization: Academic Institution

Role: Organizational Official

Date Submitted: 10/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): La Trobe University's research portfolio covers a broad range of disciplines, including biomedical, microbiological, infectious disease, molecular and cell biology, agricultural, veterinary, environmental, and biotechnology research.

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: La Trobe University supports NIH's objective of strengthening and modernizing biosafety oversight for research involving biohazards. For international institutions, however, clarification is needed regarding the scope of application. The draft policy appears capable of extending oversight obligations beyond NIH-funded activities to broader institutional research programs. We recommend that the policy apply to NIH-funded research and activities that directly support or are materially connected with NIH-funded research. Australian universities already operate under mature statutory and institutional biosafety systems, including the Australian Gene Technology Scheme, biosecurity legislation, institutional biosafety committee oversight, and Australian/New Zealand standards for microbiological safety and containment. Where institutions operate within established national biosafety frameworks, the policy should recognize equivalent biosafety outcomes rather than requiring duplication of US-specific requirements. NIH should also provide clear guidance on how the policy applies to foreign recipients, subrecipients and collaborators, particularly where domestic legal or regulatory requirements differ from NIH requirements.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): La Trobe University supports a tiered, risk-based oversight model that calibrates requirements according to the level of biosafety risk. We encourage NIH to ensure that oversight remains proportionate and avoids imposing unnecessary administrative requirements on lower-risk activities or research already subject to robust oversight under established national regulatory systems. For international institutions operating within mature biosafety frameworks, local oversight mechanisms should play a primary role, with additional federal requirements focused on areas of elevated risk or where specific NIH interests require additional assurance. A risk-based approach should minimise duplication while maintaining high biosafety standards.

3. Continued utility of Risk Groups: Risk Groups remain a useful reference point for assessing intrinsic agent hazards; however, containment and operational requirements are ultimately implemented through facility and procedural controls. For institutions outside the United States, it is important that NIH provide guidance on how alternative classification systems relate to the proposed framework. Australian institutions typically use Physical Containment (PC) classifications rather than Biosafety Levels (BSL). NIH should therefore clarify how PC levels, Risk Groups, BSL and ABSL classifications align for the purposes of compliance and oversight. Such guidance would improve consistency and reduce the risk of unnecessary duplication or conflicting interpretations.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should consider establishing a foreign-assurance or equivalency pathway for institutions operating under mature domestic biosafety systems. Under such a framework, institutions could demonstrate that their regulatory environment and internal governance arrangements achieve biosafety outcomes comparable to NIH expectations without requiring full duplication of US-specific processes, terminology or committee structures. A proportionate assurance mechanism would encourage continued participation by international collaborators while maintaining appropriate accountability and biosafety standards.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: The draft templates appear useful for promoting consistency and transparency. For international institutions, NIH should consider allowing reasonable flexibility where local reporting frameworks, incident notification requirements, recordkeeping standards or committee procedures differ from US practice. The templates should be positioned as models that can accommodate equivalent information generated through established institutional and national systems. This approach would reduce unnecessary administrative burden while preserving the intent of consistent reporting and oversight.

6. Other feedback relevant to this resource: Additional guidance would be particularly valuable for foreign recipients and collaborating institutions. Priority areas include: Clarification of the scope of activities covered by the policy. Criteria for determining when research is materially connected to NIH funding. Guidance on managing conflicts between NIH requirements and domestic legal obligations. Mapping of international biosafety classification systems, including Australian Physical Containment levels, against NIH Risk Groups and Biosafety Levels. Development of a foreign-assurance or equivalency framework. Worked examples involving institutions with mixed NIH-funded and non-NIH-funded research portfolios. A reasonable transition period to enable institutions to assess impacts and implement any required governance changes.

Description: Email Submission from: La Trobe University

La Trobe University Response to the Draft NIH Biosafety Policy for Research Involving Biohazards

La Trobe University supports NIH's objective of strengthening and modernising biosafety oversight and recognises the importance of maintaining robust, transparent and risk-based governance arrangements for research involving biohazards.

As an Australian university, La Trobe operates within an established regulatory framework that includes the Australian Gene Technology Scheme, biosecurity legislation, institutional biosafety committee oversight arrangements, and Australian/New Zealand standards governing microbiological safety and physical containment. These systems provide legally enforceable biosafety requirements and are supported by institutional governance, training, monitoring and incident management processes.

Our principal concern is that the draft policy may be interpreted as applying beyond NIH-funded research to broader institutional research activities that have no direct relationship with NIH funding. We encourage NIH to limit the scope of the final policy to NIH-funded research and activities that directly support, or are materially connected with, NIH-funded research.

We also encourage NIH to recognise equivalent biosafety outcomes achieved through mature host-country regulatory systems. Requiring international institutions to duplicate US-specific terminology, classifications, review processes, committee structures and reporting arrangements may create significant administrative burden without necessarily improving biosafety outcomes.

To support international engagement while maintaining appropriate accountability, NIH should establish a foreign-assurance or equivalency pathway for institutions operating within established national biosafety frameworks. Such an approach could allow institutions to demonstrate that domestic regulation and institutional oversight achieve outcomes comparable to NIH expectations without requiring wholesale duplication of US administrative requirements.

Additional guidance would be beneficial regarding the application of the policy to foreign recipients, collaborators and subrecipients, particularly where domestic legal obligations differ from NIH requirements. Guidance mapping Australian Physical Containment classifications to NIH Risk Groups and Biosafety Levels would also assist implementation.

La Trobe University supports strong, risk-based biosafety oversight and remains committed to meeting appropriate requirements for NIH-supported research. We encourage NIH to adopt a proportionate framework that provides assurance to NIH

while recognising effective host-country regulatory systems and avoiding unnecessary duplication for international institutions.

RE: Comments on the Draft NIH Biosafety Policy for Research Involving Biohazards

October 16, 2026

I am the Biological Safety Officer for an R1 institution and have spent the past decade in the biosafety profession. Before that, I was the principal investigator (PI) of a biomedical research laboratory for more than a decade. I have a PhD in cell biology and hold the Registered Biosafety Professional (RBP) credential from the American Biological Safety Association. **These comments are my own and do not represent the opinions of my current or past employers.**

During my 25 years as a researcher (including 3 years as an undergraduate, 5 years of graduate school, 6 years of postdoctoral training, and 11 years as PI), much of my research was directly or indirectly funded by the NIH. For decades the NIH has supported the training of the biomedical workforce and enabled biomedical innovations that save lives.

I applaud the NIH for seeking to modernize its biosafety and biosecurity framework by replacing the now dated *NIH Guidelines*, and for sincerely engaging with the biosafety and research communities as well as the public during this process.

This is a significant overhaul, not minor tweaks of the longstanding *NIH Guidelines*. There is much to laud in the draft NIH Biosafety Policy for Research Involving Biohazards and there is room for improvement. **I therefore urge the NIH to provide the opportunity for additional public comments on the next draft of the Biosafety Policy before it is finalized and institutions are directed to implement it.**

My specific comments on this draft are provided below.

<u>What the policy gets right:</u>

- Reinforcing institutional accountability for biosafety programs through the addition of the Biosafety Assurance statement
- Limiting the scope to biomedical research, which fits within the mission of the NIH
- Expanding the scope to include non-recombinant/synthetic nucleic acid-based biohazards such as wildtype pathogens and biological toxins
- Removing prescriptive containment levels and practices and empowering the Institutional Biosafety Committee (IBC) to apply local risk assessments
- Using risk groups (RGs) as a starting point for risk assessment, not the endpoint
- Creating a delegated review level for lower risk research

- Narrowing the circumstances when NIH approval is needed to those with greater uncertainty or higher risk
- Narrowing and more precisely defining when incidents must be reported to NIH
- Committing to NIH generating and publishing an Annual Incident Summary Report to identify trends that may guide safety training and incident prevention programs

Areas where improvement is needed:

- **The scope of the policy is unclear.** Section II defines the scope as limited to research involving known or potential risk to human health, but this is muddied throughout the policy by references to ecological and environmental risks and inclusion of RG1 organisms and transgenic animals at BSL1/ABSL1.
- **The timeline for implementation is too short.** Implementation of the new Biosafety Policy will require significant overhauls at many institutions, including revamped IBCs and committee workflows, biosafety protocol software updates, and new or expanded staffing models. Six months may fall within a single fiscal year, making it challenging to adjust budgets or allocate additional resources. This is particularly true for smaller institutions that cannot rapidly deploy resources and public schools that rely on state commitments.
- **Many key definitions are poor or missing.** Risk groups are mentioned throughout the policy but are not defined in it. GDMOs are mentioned but not defined. "Biological agent" should be changed to "Biohazardous agent", as not all biological materials cause human disease. A toxin is defined as a "protein or peptide … that causes harm in humans", but not all toxins are proteinaceous, and not all harmful proteins are toxins.
- **Biosafety Officers (BSOs) are given more responsibility without accompanying authority.** The NIH Biosafety Policy sets forth oversight responsibilities for the BSO (e.g., conducting inspections, investigating incidents), but does not require institutions to give BSOs the authority to correct problems that they identify. The policy does not define the qualifications for BSOs. Institutions are not even required to have a BSO unless they have research at BSL3/BSL4 or GDMOs. BSOs should be analogous to Institutional Officials that support IACUCs and oversee animal programs, with authority commensurate with their responsibilities.
- **Posting incident reports on a public website compromises personal privacy and endangers safety culture.** While I appreciate the NIH's attempts to improve transparency, publicly sharing incident reports will deter reporting. For smaller laboratories or those working in specialized areas, the inclusion of details such as PI name, specific research materials, and position titles will make it all too easy to identify individuals involved in incidents. This compromises privacy and makes it easier for nefarious actors to target individuals (e.g., animal rights extremists). The inclusion of treatment information can inadvertently reveal information about an individual's personal health status. Together, these considerations will create a safety culture in which unsafe conditions and practices go unreported and unaddressed out of fear of reprisal or adverse consequences.

- **Mandating use of specific templates adds administrative burden.** While I appreciate that the NIH is creating tools to aid implementation of the policy, requiring the use of specific templates does not allow institutions the flexibility to tailor implementation to fit existing processes and workflows. For example, many institutions use software programs to automate creation of IBC minutes. Requiring a specific template be used will mean either reprogramming software or manually creating the minutes. This adds burden without improving safety.
- **The NIH sets timelines for institutions but not for themselves.** Institutions are given six months to implement the new Biosafety Policy; the NIH intends to provide implementation resources but has made no commitment to have these available when the clock starts ticking. Institutions must submit initial incident reports within 24 hours and full incident reports within 30 days, while the NIH commits to no specific turnaround for reviewing and responding to incident reports, saying only that these will be done "in a timely manner". Requests to lower containment are also reviewed "in a timely manner" and no timeframe is given for publishing approved determinations. Why is the NIH not held to the same standards as the institutions they fund?
- **Delegated review shifts but does not reduce administrative burden.** Delegated review will allow the IBC to allocate more of its meeting time where it is needed most, the review and discussion of higher risk research. It does not, however, reduce the number of biosafety protocols that researchers need to create and institutions must process, review, and track. The *NIH Guidelines* specifically described exemptions for certain low-risk materials, but if these exist under the draft Biosafety Policy, they are no longer explicitly called out.

<u>Summary of my recommendations:</u>

- Clarify the scope of the policy, preferably by explicitly limiting it to research that poses a <u>direct</u> known or potential risk to human health (e.g., pathogen or vector of human disease)
- Extend the timeline for implementation to two years
- Every institution that has research with biohazardous materials subject to the policy should be required to have a BSO(s)
- BSOs should be given the authority to enforce the NIH and institutional policies related to biosafety and biosecurity
- Replace the requirement to post individual incident reports on a public website with a requirement to post aggregated and anonymized incident data
- Provide templates but make their use optional
- Provide implementation guidance at go-live, including online FAQs, a monitored email address and dedicated phone number for live assistance
- Set a standard timeline for the NIH to respond to incident reports and requests to set or lower containment, including publication of these determinations
- Explicitly exclude lower risk research and research that falls under the oversight of another federal agency to reduce unnecessary administrative burden, including:

- Genetically modified organisms at BSL1/ABSL1, especially common animal models such as laboratory-bred rodents, fish, frogs, fruit flies, and non-parasitic nematodes
- Recombinant RG1 organisms that are not modified such that they pose a risk to human health, especially common host vector systems used for cloning and protein purification such as RG1 *E. coli* and *S. cerevisiae*
- Genetically modified cell lines that do not produce and have not been administered biohazardous agents
- *Ex vivo* work with isolated plasmids or constructs that do not pose a risk to human health outside of an organism
- Human-derived materials covered by the OSHA Bloodborne Pathogen Standard 29 CFR 1910.1030
- Select agents and toxins covered by 7 CFR Part 331, 9 CFR Part 121, and 42 CFR Part 73

Thank you for the opportunity to provide feedback on the draft NIH Biosafety Policy.

Sincerely,

Andrea N. Ladd, Ph.D., RBP (ABSA)

535. Oak Ridge National Laboratory

I am responding: On behalf of an organization

Name: Anuj Kapadia

Name of Organization: Oak Ridge National Laboratory

Type of Organization: Government Agency

Role: Organizational Official

Date Submitted: 10/20/2026

Domain of research most important to you or your organization (e.g. cognitive neuroscience, infectious epidemiology): Biosecurity, Biodefense, Computational drug discovery

1. Appropriateness of the scope of the new policy, including the definition of biohazards for the purpose of oversight and any inadvertent gaps in oversight that should be addressed: ORNL supports expanding oversight beyond recombinant and synthetic nucleic-acid research. Biological risk can arise from wild-type pathogens, toxins, prions, serial passage, reassortment, directed evolution, and other methods not captured by the current framework. ORNL already reviews biological hazards under DOE requirements, including 10 CFR 851, Appendix A, Section 7, using BMBL principles.
However, the definition should be limited to a reasonably foreseeable, non-de minimis risk under the proposed experimental conditions. For example, genetic modification or use of a toxin should not automatically trigger substantive review without considering pathogenicity, dose, route, scale, replication competence, environmental stability, and available countermeasures.
NIH should recognize equivalent oversight by DOE, defense and national-security agencies, CDC/USDA, and other federal authorities. Receipt of any NIH funding should require an adequate institutional biosafety program but should not automatically give NIH project-level authority over classified, controlled, proprietary, or non-NIH-sponsored research. The cognizant federal agency should serve as the lead authority.
The policy should also address AI-biotechnology convergence. Purely computational research should not automatically fall under IBC oversight, but review may be warranted when computational work is linked to creating or validating a biological agent or producing an actionable information hazard. NIH should coordinate with the July 2026 USG high-risk life-sciences policy and provide guidance on biological design data, model access, third-party AI systems, cybersecurity, export controls, and foreign-national access.

2. Appropriateness of tiered oversight and calibration to risk (i.e., federal vs local): A tiered system is appropriate. Local IBCs should remain the primary reviewers because they understand institutional facilities, personnel, procedures, and emergency capabilities. Delegated review is appropriate for well-characterized, lower-risk work; full IBC review should focus on significant or uncertain hazards; and federal review should be reserved for novel or emerging agents, initial reductions in containment for RG3/RG4 agents, and research with potentially high-consequence implications.
The final policy should establish a lead-federal-agency and mutual-recognition principle. Research reviewed under equivalent DOE, defense, intelligence-community, Select Agent, or other federal

requirements should not undergo duplicative NIH approval. The cognizant sponsor should be primary for approval, enforcement, incident response, and information control.
For classified or controlled work, NIH should permit review by the sponsoring agency or an appropriately cleared institutional body and accept an unclassified certification in place of protected project details. Defined review timelines, expedited review for urgent public-health or national-security work, an appeal process, and a transition period for existing projects are also needed.

3. Continued utility of Risk Groups: Risk Groups and Biosafety Levels are complementary, not competing. RG provides a useful baseline assessment of an agent's intrinsic hazard. BSL describes the facilities, practices, equipment, and controls necessary to perform a specific activity safely and is therefore an outcome of the experiment-specific risk assessment.
NIH should retain RG classifications as an initial screen while requiring a BMBL-consistent assessment of the agent, modifications, proposed manipulations, route of exposure, aerosol or sharps risk, scale, animal use, environmental stability, available countermeasures, and scientific uncertainty.
For genetically modified agents, the highest RG associated with a source sequence may be a conservative screening consideration but should not automatically determine containment. A short, nonfunctional sequence from an RG3 agent does not necessarily give an RG1 host the same risk profile. Conversely, low-risk components may combine to produce a higher-risk phenotype. Functional properties and experimental context should determine the final BSL. NIH should provide worked examples for attenuated strains, replication-defective vectors, directed evolution, synthetic constructs, and AI-generated (or reverse-engineered) sequences.

4. Mechanisms to encourage and accommodate voluntary compliance for research not subject to the policy (e.g., at non-NIH funded institutions): NIH should encourage voluntary compliance through assistance and incentives rather than unfunded mandates. Useful mechanisms include model policies, decision tools, training, technical consultation, shared or external IBCs, transition funding, and recognition of equivalent federal or accredited biosafety programs.
Voluntary near-miss reporting should be confidential, de-identified, and protected from enforcement or routine public disclosure unless the event involves a material exposure, release, laboratory-acquired infection, or comparable risk. A national laboratory already operating under 10 CFR 851 and the BMBL should be able to demonstrate equivalent compliance without creating a separate NIH-specific system.

5. Comments on Draft Incident Reporting and Draft Meeting Minutes Templates: Standardized templates can improve consistency, but official regulatory records should be separated from public communications.
For incident reporting, 24-hour notification is appropriate for laboratory-acquired infections, consequential releases, significant high-containment failures, and material noncompliance. Lower-risk events managed locally should remain institutional records rather than being individually posted online. Public disclosure of minor events could discourage reporting while obscuring genuinely important incidents.
For NIH-reportable incidents, institutions should submit a complete official report but publish only a de-identified, security-reviewed summary. Public reports should not be required to identify the PI, agent, construct, sponsor, facility, exposure pathway, or security vulnerability when disclosure could compromise national security, personnel safety, export controls, intellectual property, or sponsor confidentiality.
Similarly, full IBC minutes should document the committee's review, while the public version should be a

sanitized summary demonstrating that risks and controls were appropriately evaluated. Absolute prohibitions on redacting PI names or other fields are inappropriate. Classified or controlled work should be reported through sponsor-approved channels, with NIH accepting an unclassified certification or sanitized summary. These protections should align with the July 2026 USG policy, which expressly protects national-security, research-security, business-sensitive, and legitimate intellectual-property information.

6. Other feedback relevant to this resource: Before implementation, NIH should provide:
• Decision trees and examples defining covered, delegated, full-IBC, federal-review, and excluded research.
• Crosswalks among the NIH policy, 10 CFR 851, BMBL, Select Agent requirements, OSHA, export controls, and the July 2026 USG high-risk life-sciences policy.
• Lead-agency, reciprocity, and conflict-resolution procedures.
• Processes for classified, CUI, export-controlled, proprietary, and sponsor-restricted research.
• Guidance on AI-assisted biological design, model weights, training data, cloud AI services, foreign-national access, cybersecurity, and information hazards.
• A process for limiting data or model release when open disclosure could enable harmful biological design or compromise national or economic security.
• Examples translating RG, genetic modification, experimental activity, and uncertainty into BSL decisions.
• Clear thresholds for immediate NIH reporting, local review, near-miss reporting, and events requiring no formal report.
• Uniform standards for security, privacy, proprietary, and sponsor review before public disclosure.
• Guidance on aligning IBC responsibilities with the Institutional Review Entity required by the USG high-risk-research policy.
• Procedures for multisite studies, external IBCs, user facilities, and subcontractors.
• A reasonable transition period, grandfathering of existing approvals, defined NIH response times, and implementation support.
The final framework should create a common national standard while allowing institutions to satisfy it through existing, effective biosafety programs. Success should be measured by improved risk identification and incident prevention, not by the volume of reviews or public records generated.
